delivered by conventional AAV generally exist as extrachromosomal episomes, and are not propagated during the continuous cell division that occurs early in life. Repeat dosing of current AAV platforms is challenging due to the strong anti-capsid immune response in humans, rendering AAV generally unsuitable for gene therapy treatment in pediatric patients. The super piggyBac® DNA insertion system enables stable integration of a therapeutic transgene into the genome, and comprises two components: 1) a piggyBac transposon, containing the therapeutic gene of interest (GOI) expression cassette, and 2) the super piggyBac transposase (SPB), which is responsible for excising the GOI from the transposon and pasting it into the genome. We sought to develop a super piggyBac hybrid system suitable for liver-directed gene therapy, utilizing existing AAV capsids to deliver the transposon, and a novel liver-directed LNP to deliver an mRNA encoding SPB (LNP-SPB). A broad in vivo screening campaign utilizing design of experiment (DoE) models was performed to identify and optimize biodegradable LNP formulations capable of specific and high-efficiency delivery of mRNA to the mouse liver. Expression of the SPB protein in liver was dose-proportional and transient, peaking between 2-4 hours and declining to undetectable levels within several days. Tandem mass spectroscopy studies demonstrated clearance of the novel ionizable lipid from the liver within several hours following intravenous administration. The LNP was well-tolerated, with no clinically significant changes in body weight, complement activation, or clinical chemistry at doses up to 2 mg/kg. Evaluation of the LNP in adult cynomolgus demonstrated a similar liver-tropic biodistribution as in mice, and no clinically meaningful tolerability signals were observed at all doses evaluated. We evaluated three liver-tropic AAV capsids for delivery of a piggyBac transposon: AAV8, AAV9, and KP1. Each capsid was able to be successfully manufactured at small scale with a transposon comprising a therapeutic human gene and the piggyBac inverted terminal repeats. Co-administration of each capsid with the LNP-SPB to neonatal (day=1 of life) mice resulted in substantial (20-60%) transduction of hepatocytes, which was maintained into adulthood. Between 1-4 integrated copies of the GOI per diploid genome were detected by ddPCR in the animals treated with AAV + LNP-SPB. Administration of each capsid alone (without the SPB LNP) to neonatal mice resulted in minimal (<3%) hepatocytes expressing the GOI, presumably due to dilution of the episomal transgene during liver growth. Co-administration of the LNP-SPB with AAV did not result in any detectable tolerability concerns. In a mouse model of the urea cycle disorder ornithine transcarbamylase deficiency (OTCD), we observed that disease resolution could be achieved with significantly lower doses of AAV when combined with the LNP-SPB relative to AAV alone. These data demonstrate the versatility of the piggyBac hybrid platform, which can be deployed effectively in a variety of AAV capsids. Further, we demonstrate the advantage of this system for achieving durable transgene expression when administered early in life and at lower total AAV doses.

1319 Rationally Designed Cardiotropic AAV Capsid Demonstrates Targeted Cellular Distribution in Cardiomyocytes

Youjun Chen[1], Ferzin Sethna[1], Abbie Svancarek[1], Cody L. Evans[1], Joshua T. Hatfield[1], Timothy D. Henry[2], Eugene Chung[2], Sheila Mikhail[1], Roger J. Hajjar[1], Anna P. Tretiakova[1], R. Jude Samulski[1,3]

[1]Asklepios BioPharmaceutical, Inc. (AskBio), Research Triangle Park, NC,[2]The Christ Hospital, Cincinnati, OH,[3]Gene Therapy Center and Department of Pharmacology, University of North Carolina, Chapel Hill, NC

Congestive heart failure (CHF) is a progressive disease that is characterized by the heart's inability to pump adequately to meet the body's demands. This widespread condition has a critical unmet medical need. Recent advances in understanding the molecular basis of myocardial dysfunction have resulted in AAV gene-therapy (GT) clinical trials for heart failure. Cardiac tissue analysis from earlier clinical trials that failed to show efficacy revealed poor vector transduction. A novel cardiotropic and liver de-targeted capsid, AAV2i8, was rationally designed to overcome poor transduction in cardiac tissue. Our clinical trial for the treatment of non-ischemic cardiomyopathy uses the AAV2i8 capsid to deliver a constitutively active protein phosphatase 1 inhibitor 1 (I-1c). We previously reported that molecular evaluation of vector performance from left ventricular biopsy tissue of a subject enrolled in our trial revealed high vector transduction and mRNA expression. We also observed restoration of depressed S16 phosphorylation of phospholamban, which is associated with abnormal intracellular calcium handling, a key cellular abnormality in CHF. The molecular studies performed previously provide a confirmation of our vector efficacy (ASGCT 2022). Here we report development of cellular distribution methods to study our vector behavior at the cellular level. Probes targeting the CMV promoter region and I-1c transgene region were designed for RNAscope, a recently developed in situ hybridization method allowing detection of cellular and subcellular localization of the vector genome DNA and I-1c mRNA in the mouse heart tissue and human biopsy. Wheat germ agglutinin (WGA) was used to label cell membrane and cardiomyocytes were distinguished from endothelial cells that were co-stained with Isolectin B4 (IB4) in mouse heart tissue. Method optimization was performed in control human and mouse hearts. Mice were injected with saline or AAV2i8 I-1c vector through tail vein and sacrificed at 14 days post injection. Heart tissues were harvested, snap frozen on dry ice and cryosectioned at a thickness of 10μm. Heart sections were subjected to fluorescent RNAscope assay followed by WGA and IB4 staining. Nuclei were visualized by 4',6-diamidino-2-phenylindole (DAPI) staining. We found that transduced vector genomes and I-1c mRNA were predominantly observed in cardiomyocytes of mouse heart tissue, demonstrating that our vector efficiently transduces its target cells within the myocardium. Examination of control human heart tissue by RNAscope and cellular and subcellular marker staining showed that I-1c was not detectible in the absence of AAV2i8 I-1c vector administration. Here we present cellular distribution of our vector in the human left ventricular biopsy. These data underscore the importance of obtaining molecular quantitation as well as cellular distribution of vector performance for novel capsids in human tissues, and also support the validity of our GT approach towards the treatment of heart failure.

1320 A Lipid Nanoparticle Toolkit to Correct Cystic Fibrosis in Airway Stem Cells

Ruth Foley[1], Paul Ayoub[2], Emily Duggan[3], Josh Khorsandi[3], Diego Banuet[3], Arunima Purkayastha[3], Donald B. Kohn[3], Brigitte Gomperts[3], Steven J. Jonas[3]

[1]Bioengineering, University of California, Los Angeles, CA,[2]Molecular & Medical Pharmacology, University of California, Los Angeles, CA,[3]Pediatrics, University of California, Los Angeles, CA

Aim: Cystic fibrosis (CF) is a monogenic disorder resulting from mutations in the cystic fibrosis transmembrane conductance regulator (*CFTR*) gene that leads to chronic lung infections & respiratory failure. Effective delivery of biomolecules to self-renewing airway basal stem cells (ABSCs) for gene correction in the CF airway has been especially difficult because of their protected location within the epithelium. We report the design and testing of a gene therapy strategy that utilizes lipid nanoparticles (LNPs) configured to: i) access ABSCs by penetrating the dehydrated mucus layer in the CF airway *via* surfactant-incorporating liposomes engineered for epithelial disruption (LNP 1) and ii) package & deliver *CFTR*-directed CRISPR/Cas9 gene editing payloads to exposed ABSCs (LNP 2). Methods: We utilized electroporation of Cas9 ribonucleoprotein complexes into immortalized human bronchial epithelial cells (16HBE14o-) to screen various single-guide RNA constructs (sgRNAs) for their ability to edit within the endogenous *CFTR* 5' untranslated region (UTR) and integrate a reporter cassette encoding green fluorescent protein (GFP). Integration was measured *via* digital-droplet PCR. LNP formulations were synthesized *via* microfluidic mixing or rapid ethanol dilution and characterized by dynamic light scattering. Primary bronchial cells were cultured at an air-liquid interface (ALI) to mimic the epithelial structure of the human airway. The ALIs were exposed to LNP 1 suspensions, and ABSC exposure and epithelial repair was assessed *via* confocal microscopy. Flow cytometry was used to quantify transfection of 16HBE14o- cells treated with LNP 2 formulations loaded with mRNA transcripts encoding GFP. Particle formulations found to produce transfection efficiencies of >50% were applied to deliver *CFTR* gene editing cargoes. Editing efficiencies in 16HBE14o- cells were evaluated *via* tracking of insertion-deletions by decomposition. Results: We identified a sgRNA with >95% cutting efficiency, no detected off-target editing, and integration rates of 10-15% at the *CFTR* 5'UTR. We incorporated a primary amine with a 6-carbon linker to the 5' end of double-stranded DNA donor cassettes *via* PCR amplification to increase integration by 2-fold over traditional donors. We identified LNP 1 formulations containing the surfactant polidocanol capable of transiently exposing ABSCs in ALI cultures. Compared to polidocanol alone, LNP 1 induced similar degrees of ABSC exposure with more extensive epithelial repair 24h after treatment. We evaluated several LNP 2 formulations integrating different ionizable lipids for RNA delivery. Optimal LNP configurations contained the ionizable lipid SM-102, which, when packaged with mRNA transcripts encoding GFP, achieved transfection rates *ca.* 70% in 16HBE14o- cells and preserved *ca.* 80% cell viability. Editing efficiencies of *ca.* 10% were observed with particles prepared with SM-102 packaged with mRNA transcripts encoding Cas9 and a sgRNA targeting *CFTR*, compared to <3% with particles containing other ionizable lipids. Conclusion: We have designed gene editing biomolecules to effectively target *CFTR,* and demonstrated encapsulation & functional delivery of these reagents to airway epithelial cells. We have further developed strategies to access target ABSCs with minimal injury. The tools and methods developed here serve as building blocks for establishing CF gene therapy solutions poised to accelerate progress toward our collective goal to find a permanent cure for CF.

1321 Production, Purification and Characterization of Engineered ARRDC1-Mediated Microvesicles Using a Scalable Manufacturing Platform

Kristin Luther[1], Ali Navaei[2], Leah Gens[1], Carson Semple[1], Pearl Moharil[1], Ilaria Passalacqua[3], Komal Vyas[1], Qiyu Wang[1], Shu-Lin Liu[1], Lucy Sun[1], Senthil Ramaswamy[4], Davide Zocco[3], Joseph Nabhan[1]

[1]Vesigen Therapeutics, Cambridge, MA,[2]Lonza, Rockville, MD,[3]Lonza, Siena Toscana, Italy,[4]Lonza, Basel, Switzerland

Clinical evaluation of extracellular vesicle-based therapies requires development of robust production and purification processes to enable scalable and consistent GMP manufacturing. Here we report purification and characterization of a class of engineered extracellular vesicles called ARMMs (ARRDC1-mediated microvesicles) using a transient transfection-based or a stable producer cell line production process. For transient transfection, HEK5B8 suspension cells were transfected with ARMMs loading constructs using polyethyleneimine. We also engineered HEK5B8 cells to stably produce ARMMs loaded with GFP as a cost-efficient and consistent source of engineered ARMMs that overcomes the challenges of variability and reduction in viable cell density often observed following transient transfection. Material generated using either ARMMs production approach were evaluated using several analytical methods to quantify size, loading efficiency and homogeneity. The methods used included nanoparticle tracking analysis, western blotting, ELISA and nanoFCM single particle analysis. Data supported using a stable producer cell line for scalable production of engineered ARMMs. HEK5B8 stable ARMMs producers were scaled in a 3L batch process and ARMMs purification was carried out using an optimized industrial process. Lastly, we tested uptake of ARMMs *in vitro*, and *in vivo* in mice. Intravenous administration led to robust uptake of ARMMs in the spleen and liver. These data were in line with lab scale generation and evaluation of ARMMs, supporting their future manufacturability for evaluation in clinical trials.

1322 Comparison between Droplet Digital PCR and Quantitative PCR for Adeno-Associated Virus Infectious Titer Assay

Tam Duong, James McAllister, Khalid Eldahan, Jennifer Wang, Eric Onishi, Kate Shen, Robert Schrock, Bingnan Gu, Peng Wang

Lonza Houston Inc., Houston, TX

Recombinant adeno-associated virus (rAAV) has been utilized successfully for *in vivo* gene delivery for the treatment of a variety of human diseases. There is a critical need for the development of robust analytical methods to sustain the growth of rAAV gene therapy products and ensure safe and appropriate therapeutic dosages selected for treatment. $TCID_{50}$ assay (50% Tissue Culture Infectious

Dose) is an *in vitro* cell-based method widely used to determine AAV infectivity and this assay is historically viewed as a challenge due to its high variability. Currently, quantitative real-time PCR (qPCR) serves as the end-point method to detect the amount of replicated viral genome after infection. Here, we evaluate how well the droplet digital PCR (ddPCR) can be adapted into $TCID_{50}$ assay as an end-point detection method. By direct comparison between qPCR and ddPCR read-out, we observed a trend of improved inter-assay precision when the ddPCR method is utilized. Particularly, we offer improvements of $TCID_{50}$ infectious titer assay with: (1) higher precision and sensitivity by adapting ddPCR as an end-point method without standard curve preparation; (2) identification of an important second "set threshold" value in infectivity scoring; and (3) application of statistical analysis to identify the acceptance range of infectious titer values. Taken together, we provide an optimized $TCID_{50}$ method with improved accuracy and robustness that is important for rAAV infectious titer testing during process development and manufacturing.

1323 *In Situ* Production of Extracellular Vesicles

Samantha Roudi, Samir EL Andaloussi, Dhanu Gupta
Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden

Introduction: Nucleic acid-based medicines have opened a new avenue in drug discovery, allowing targeting, expression, or silencing of essentially any gene. However, the major challenge for their therapeutic utility remains functional encapsulation to ensure their stability and efficient delivery. In the past decade, extracellular vesicles (EVs) have emerged as a next-generation drug delivery system owing to their intrinsic ability to efficiently convey macromolecules. As native nanoparticles, EVs benefit from immune tolerance as well as the ability to cross biological barriers to reach distant organs such as the brain and intestine. Importantly, they can be engineered to carry macromolecules of interest. Despite enormous progress in the development of EVs for therapeutic purposes that brought them from pre-clinical studies to various clinical trials, successful transition to clinical applications remains challenging. Current approaches in above-mentioned studies and clinical trials use exogenously produced EVs, manufacturing of which at large scale requires investment in process development capabilities and notably, exert faster plasma clearance, requiring reoccurring administrations. To address this, we have developed a novel platform, "in situ EV production", where we have utilized gene therapy modalities to engineer cells *in vivo* to harness endogenously secreted EVs for delivery of biotherapeutics to hard-to-reach organs. **Methods and results:** Building upon advanced EV engineering strategies to load macromolecules, previously developed in our lab, we tagged an EV sorting domain with Nanoluciferase (NLuc) for highly sensitive tracking of in situ produced EVs. The EV engineering transgenes were administered either as a plasmid DNA via high-pressure injection or as mRNA encapsulated into lipid nanoparticles (LNPs). Importantly, both these delivery strategies have tropism to the liver and in part to the spleen. Consequently, produced EVs are primarily of hepatic origin, which is reflected in the high Nluc signal in liver. Importantly, NLuc tagged EVs showed a body-wide distribution to all major organs, including hard to reach tissues such as the CNS. In other words, we achieved sustained release of engineered EVs in circulation and showed a drastic increase in pharmacokinetic profile over exogenously administered EVs. This approach, however, is only applicable for transient production of EVs due to the relatively short expression of LNP formulated transgenes. To achieve long-term in situ production of EVs, we administered NLuc tagged EV transgenes as a ssDNA incorporated into adeno-associated viruses (AAVs). Over a period of 4 weeks, we observed increasing NLuc activity in serum, proving sustained release of in situ produced Nluc EVs to the bloodstream. At endpoint, we detected NLuc EVs throughout the body, including pancreas, brain and intestine. For assessment of functional protein delivery, we used Cre recombinase loaded EVs in an Ai9 mouse model, which induces expression of the fluorescent reporter TdTomato upon successful recombination. The EV engineered transgene was administered in AAVs and functional transfer of Cre-loaded EVs was assessed by flow cytometry of single cell suspensions and immunohistochemistry of murine tissues. TdTomato positive cell populations were detected in all major organs analyzed, demonstrating functionality of *in situ* produced Cre-loaded EVs. Furthermore, using in situ approach, our preliminary data on therapeutic versatility showed promising results in murine model of Chron´s disease. In summary, we have developed platform for endogenous production of engineered EVs using liver as a biofactory. Considering its applicability for short and long-term EV release, as well as advanced EV engineering approaches, we are confident that this innovative and versatile platform could be repurposed for the delivery of any desired biotherapeutic cargo.

1324 A Simple and Efficient Feeder-Free Workflow for Expanding and Genome Editing Blood Natural Killer Cells

Tim A. Le Fevre, Elaine Ang, Danielle Nguyen Truong, Grace Bodykevich, Jennifer Antonchuk, Andy I. Kokaji, Allen C. Eaves, Sharon A. Louis, Nooshin Tabatabaei-Zavareh
STEMCELL Technologies, Inc., Vancouver, BC, Canada

Natural killer (NK) cells are innate lymphocyte effectors that kill cancerous or virus-infected cells and can modulate immune responses by secreting proinflammatory cytokines. NK cells show immense promise for immunotherapies targeting challenging cancers such as solid tumors. The development of such cellular therapies requires the ability to genetically engineer and generate clinically relevant numbers of functional NK cells. We have developed a serum-, xeno-, and feeder-free culture system that enables the expansion and genetic manipulation of peripheral blood NK cells. Fresh human NK cells were obtained from peripheral blood leukapheresis using EasySep™ magnetic isolation and were either cultured immediately or cryopreserved in CryoStor® CS10. Fresh or thawed NK cells were cultured in ImmunoCult™ NK Cell Expansion Medium in plates coated with ImmunoCult™ NK Cell Expansion Coating Material. NK cells were replated on days 7 and 10, and harvested on day 14 prior to phenotyping and functional assessment. In some experiments, NK cells were cultured until day 21 to obtain higher cell yields. The average frequency of CD56+CD3- NK cells on day 14 was 90 ± 0.7%, with 75 ± 2.1% being CD16+. After 14 days of culture, the NK cells expanded on average 66 ± 9.8-fold (mean ± SEM, n = 78), and increased to 461 ± 129-fold (n = 13) when cultured for 21 days. Cryopreserved NK cells also achieved significant

expansion after 14 days in culture, although lower than freshly isolated NK cells, with an average expansion of 30 ± 6.2-fold (n = 25). Genetic engineering is an important tool utilized in NK cell research. To ensure compatibility with CRISPR-Cas9 genome editing, NK cells were cultured for 3 - 4 days on coated plates prior to ribonucleoprotein (RNP) delivery in ImmunoCult™ NK Cell Expansion Medium. Using electroporation, ArciTect™ CRISPR-Cas9 RNP was delivered into activated NK cells, after which the cells were returned to culture. Guide RNA sequences were designed to target either CD45 or TIGIT as representative cell surface markers expressed by NK cells. Gene editing efficiencies of 91 ± 3% and 88 ± 3% of CD45 and TIGIT were observed 4 days post-electroporation, respectively (n = 4). To assess functionality, the expanded NK cells were co-cultured with K562 cells to assess natural cytotoxicity, or co-cultured with SK-BR-3 breast adenocarcinoma cells in an antibody-dependent cellular cytotoxicity (ADCC) assay. For the ADCC assay, SK-BR-3 cells were treated with anti-HER2 antibody for 30 minutes and washed prior to assessment. On average, intracellular expression of IFN-γ was observed in 49 ± 3.7% (n = 15) of K562-stimulated NK cells, and in 32 ± 4.1% (n = 7) of NK cells cultured with antibody-treated SK-BR-3 cells. Additionally, intracellular expression of TNF-α was observed in 43 ± 3.7% (n = 8) of K562-stimulated NK cells, and in 28 ± 4.1% (n = 7) of NK cells cultured with antibody-treated SK-BR-3 cells. Stimulated NK cells also expressed surface CD107a, a marker of degranulation (73 ± 5.2% for K562 co-culture, [n = 15], and 63 ± 3.3% for ADCC assay [n = 7]). Finally, NK cell target killing was measured in co-cultures. Target cells were treated with a substrate that, when cleaved by activated caspase-3/7, results in the release of a fluorescent dye. At an effector:target ratio of 1:1, an average of 50 ± 2.6% (n = 11) of K562 cells, and an average of 60 ± 2.4% (n = 7) of antibody-treated SK-BR-3 cells were killed. The work presented here highlights the suitability of our NK cell expansion system to edit and expand functional NK cells to aid in the study and development of cellular immunotherapies.

1325 Generation and Persistent Genetic Modification of Virus- and Factor-Free Human iPSCs into Kidney Organoids Using S/MAR DNA Vectors

Anna Hartley[1], Zhaoyu Du[2], Manuela Urban[1], Alicia Roig-Merino[1,3], Julia D. Peterson[1], Mehrnaz Ghazvini[2], Martin J. Hoogduijn[2], Richard P. Harbottle[1]

[1]DNA Vector Laboratory, F160, German Cancer Research Centre, Heidelberg, Germany,[2]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands,[3]MaxCyte, Rockville, MD

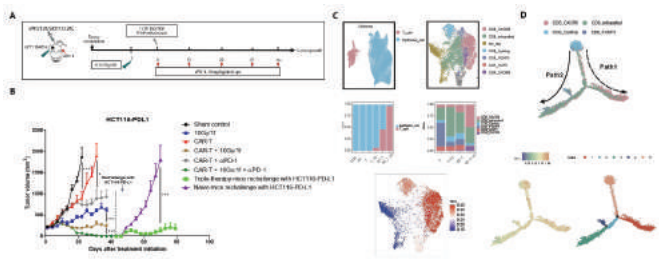
The generation of isogenic or autologous cells for cell- or organoid-based disease modelling and therapies relies on the efficient reprogramming of patient-derived cells. This is often achieved using integrating viral vectors, which carry a danger of insertional mutagenesis and oncogenesis. Alternatively, the most common non-integrative reprogramming technologies still require viral components (EBNA1/oriP, Sendai) or multiple transfection steps (RNA). These methods however cause concerns; cells reprogrammed with viral components have elevated markers of cellular damage and immune signalling, and repeat transfections increase both the cost and the risks of non-compliance with quality standards for clinical use. Therefore, to reduce these risks and improve the potential of the cells for clinical application, we have developed a method to reprogram primary human fibroblasts using fully non-viral DNA vectors, which require only a single transfection. Our vectors are based on the use of a Scaffold Matrix Associated Region (S/MAR), which is a sequence of human origin and drives autonomous episomal replication of the vector in the host cell nucleus. This allows the sustained expression of factors required for reprogramming, with loss of the vector after epigenetic silencing in the late stages of reprogramming, leading to true vector-free, factor-free human induced pluripotent stem cells (hiPSCs). We have shown that hiPSCs reprogrammed with our S/MAR vectors are morphologically and phenotypically indistinct from EBNA/oriP-derived hiPSCs, and express pluripotent stem cell markers (Tra-160, Nanog, Oct3/4, Lin28). We can also use our S/MAR DNA vectors to genetically modify hiPSCs in a stable and heritable way. Importantly, the vectors are maintained episomally at low copy number and do not damage the cells, as they retain their pluripotent capacity. The expression of the vector transgene in hiPSCs is stable over time (>150 days) in the absence of selection, and is not affected by cryogenic cell storage. In addition to this, transgene expression is stable throughout all stages of differentiation into target cell types: we have shown transgene persistence in tri-lineage differentiation of S/MAR-modified hiPSCs into germ layers as well as directed differentiation into embryoid bodies and kidney organoids. We have modified hiPSCs with S/MAR DNA vectors expressing green fluorescent protein (GFP) and erythropoietin (EPO). EPO is an endocrine factor produced by the kidneys in response to hypoxia, which stimulates erythropoiesis. EPO production is disturbed in patients with chronic kidney disease anemia or kidney transplant injury. We differentiated GFP/EPO-modified hiPSCs into kidney organoids and demonstrated that they remained fully functional, forming glomerular and tubular structures marked by podocytes and proximal and distal tubular cells, while retaining high expression levels of both GFP and EPO throughout the differentiation process. Organoids were then subcutaneously transplanted into mice and retained their structure as well as EPO expression, providing a proof-of-concept for the S/MAR DNA vector-based modification of hiPSCs for functional studies of translational applications. This study gives us the possibility to generate and modify patient-derived iPSCs using our S/MAR DNA vectors, and to differentiate these into target cell types and organoids for further study or implantation as disease models and treatments.

1327 Triple-Modality Therapy with a Dual-Targeting CD133/PD-L1 CAR-T and Anti-PD-1 Plus Radiotherapy Maximize Antitumor Response in Solid Tumor

Zhuoran Yao[1], Limei Yin[1], Yijun Wu[1], Kai Kang[1], Ren Luo[1], Hui Wang[1], Yue Zheng[1], Laduona Wang[1], Guo Lin[1], Ruizhan Tong[2], Linlu Yi[2], Jianxin Xue[1], Wenbo Wang[3], You Lu[1]

[1]Thoracic Oncology Ward, Cancer Center and State Key Laboratory of Biotherapy, West China Hospital, Sichuan University, Chengdu, Sichuan, China,[2]Laboratory of Clinical Cell Therapy, West China Hospital, Sichuan University, Chengdu, Sichuan, China,[3]Department of Oncology, Shanghai Tenth People's Hospital, Tongji University School of Medicine, Shanghai, China

Application of CAR-T therapies in solid tumors is largely hindered by tumor microenvironment (TME), which hampered CAR-T infiltration and transduced inhibitory signals to T cells. Introducing novel CAR-T modules and designing combinational strategies are necessary to overcome these obstacles. We co-expressed an αPDL1. CD28 chimeric receptor with a second generation CD133 CAR-T in a bicistronic vector. Remarkably, the αPDL1.CD28 structure **triggered the CD3ζ signaling in cis by forming clusters with CD133 CAR via CD28 dimerization**. Based on this feature, a novel dual-targeting CD133/PD-L1 CAR-T (αPDL1.28/αCD133.28ζ) was designed, which effectively eliminated either PD-L1+ or CD133+ cancer cells while reducing vector CD3ζ redundancy. **Dual CAR-T showed improved cytotoxic function against CD133+ tumor cells both in vitro and in vivo, regardless of basal PD-L1 expression**. Mechanistically, CD133+ tumor cells upregulated PD-L1 when engaging αCD133.28ζ CAR module to suppress CAR-T function, which instead increased their vulnerability to dual CD133/PD-L1 targeting CAR-T cells. The dual targeting CD133/PD-L1 CAR-T successfully hijacked the PD-L1/PD-1 axis and turned the immune escape mechanism of tumor cells into their weakness. Next, we combined our CAR-T cells with radiotherapy to further enhance the efficacy. In tumor-bearing mice, synergistic anti-tumor efficacy of mice treated with hyperfractionated radiation (10Gy/1f) and dual targeting CAR-T cells was further observed. The **triple-modality therapy with CAR T cells and anti-PD-1 plus radiotherapy maximized antitumor responses and induced complete cures in the tumor-bearing mice.**



Graphic 1. A) Treatment scheme of triple-modality therapy; B) Tumor growth in each treatment group (including rechallenge); C) Single-cell transcriptome analysis of CAR-T cells in TME, a unique CXCR6+ CD8+ CAR-T subset was identified in RT-T & RT-T-ICI group, which posed a high Trm signature; D) Pseudotiming analysis revealed that in RT+T & RT+T+ICI group, CAR-Trm was derived from cycling CAR-T cells.

Single-cell transcriptional profiling of the CAR-T cells in TME revealed that radiation induced a unique tissue-resident memory CAR-T subset that highly expressed CXCR6. In vitro co-culture of radiated tumor cells and CAR-T cells also induced a higher proportion of CAR-Trm cells. Therefore, we conclude that radiation promoted the differentiation of CAR-Trm to prolong persistent anti-tumor toxicity. **In summary**, our study for the first time introduced a novel CAR-T design with two CAR structures sharing a single CD3ζ through a membrane CD28 dimerization. Dual-targeting CD133/PD-L1 CAR-T effectively enhanced anti-tumor toxicity by overcoming the inhibitory signals from TME. More importantly, we demonstrated a rationale and efficacy to combine the novel CAR-T and anti-PD-1 with radiotherapy in solid tumor, which was a paradigm-shifting finding and was implicational for future clinical use. Our study was fully fleshed out and ready to be published.

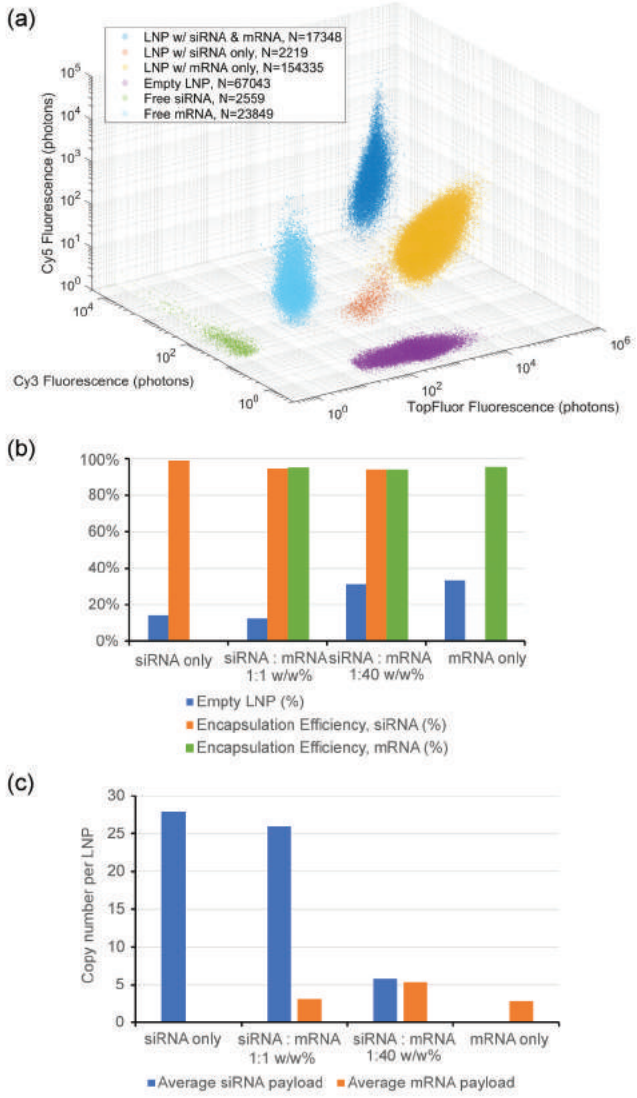
1328 Single-Nanoparticle Characterization of Co-Encapsulated Multi-Nucleic Acid Species in Lipid Nanoparticles

Sixuan Li, Yizong Hu, Jinghan Lin, Lai Wei, Kuangwen Hsieh, Fangchi Shao, Tza-Huei Wang, Hai-Quan Mao

Johns Hopkins University, Baltimore, MD

Introduction: Co-encapsulation of multi-nucleic acid species in lipid nanoparticles is an important approach of co-delivery strategies for gene editing (guide RNA and mRNA) and transcriptional modulation (mRNAs and siRNAs) [1]. In such systems, both cargos need to enter the same cell to achieve the intended functional outcomes; therefore, high co-encapsulation efficiency and tunability of the loading level of each cargo are of interest. However, current characterization techniques have limited capability to examine these features on the single-nanoparticle and populational levels, and this lack of tools is hampering the optimization efforts of the formulations. Here, we apply a recently developed technique[2] to elucidate the payload content and distribution of the RNAs in a benchmark formulation for siRNA and mRNA co-encapsulation. The findings of this study will contribute to a comprehensive understanding of the co-delivery effect. **Methods**: We used Cylindrical Illumination Confocal Spectroscopy (CICS) to examine the LNPs with Cy3-siRNAs, TopFluor-PC lipids, and Cy5-mRNAs. Fluorescence coincidence analysis was performed to classify the LNP subpopulations, and deconvolution analysis was applied to the resolve siRNA and mRNA payload in LNPs. A benchmark formulation was prepared with the dosage of ionizable lipid DLin-MC3-DMA, cholesterol, helper lipid DSPC and DMG-PEG2000 at a molar ratio of 50: 38.5: 10: 1.5. The siRNA and mRNA were mixed at a weight ratio of 1:1 or 1:40, in addition to the mRNA only and siRNA only conditions. The LNPs were formulated by rapid mixing in a T-junction at pH 4.0 and dialyzed against PBS at pH 7.4. **Results**: Using the CICS technique, we screened the LNPs at single nanoparticle resolution and identified six subpopulations including (a) LNPs with both siRNAs and mRNAs, (b) LNPs with siRNAs only, (c) LNPs with mRNAs only, (d) empty LNPs, (e) free siRNAs, and (f) free mRNAs (Fig. 1a). LNPs with siRNA: mRNA at 1:1 weight ratio had the same level of empty LNPs as LNPs with only siRNAs (Fig. 1b, 1st and 2nd group, blue bar), while LNPs with siRNA: mRNA at 1:40 weight ratio had a similar level of empty LNPs as LNPs made with only mRNAs (Fig. 1b, 3rd and 4th group, blue bar). All four formulations showed >94% encapsulation efficiency for both RNAs (Fig. 1c). The payload analysis of RNAs co-encapsulated in LNPs showed that: at 1:1 weight ratio, LNPs could accommodate around the same total number of siRNAs and mRNAs (mean = 26.0, 3.1, respectively) as the LNPs formulated with only

siRNAs (mean = 27.9) or mRNAs (mean = 2.8). Nonetheless, increasing the mRNA:siRNA weight ratio to 40:1 elevated mean mRNAs contents in the co-encapsulated LNPs to 5.4 from 2.8 for LNPs with only mRNA, which suggests that co-encapsulated siRNA may increase the loading capacity of mRNA in LNPs.



Conclusions: A new single particle analysis method is developed to characterize the co-encapsulation ability of two RNA species in lipid nanoparticles. Our findings of the distribution of the two payloads in co-encapsulated LNPs compared to LNPs formulated with single RNA species suggest that the payload capacity and co-loading efficiency may be influenced by the ratio of siRNA and mRNA. These findings in the complex assembly behavior of the RNA co-delivery in LNPs could benefit the designs of LNPs for multi-nucleic acid cargos. **References.** (1) *Nat. Nanotechnol.* **2022**, *17* (7), 777-787. (2) *Nat. Commun.* **2022**, *13* (1), 5561.

1329 Elucidating Mechanisms of *Cis* and *Trans* Cleavage to Engineer Improved Cas12a Variants

Anthony Newman

The Australian National University, Canberra, Australia

CRISPR-Cas9 gene editing technology has proven great potential for gene therapy in pre-clinical models. However outstanding issues such as on-target and off target effects, or accessibility to T-rich targets remain to be solved. CRISPR-Cas12a (formerly Cpf1) enzyme provides a complementary approach to Cas9 on T-rich regions in the genome. Commonly used Cas12a orthologues are less efficient than Cas9 for target cleavage, although editing results in fewer translocations at the target site. In addition to target cleavage, Cas12a possesses a collateral and indiscriminate '*trans*' cleavage activity, useful for molecular diagnostic applications but not considered ideal for gene editing. Our extensive study of the target cleavage preferences of three well described Cas12a orthologues have allowed the precise dissection and identify key elements in the CRISPR-Cas12a system for target cleavage, and collateral cleavage reactions. We harnessed these mechanistic insights to engineer improved variants of Cas12a; with slower off-target cleavage for more precise gene editing and modulation of the collateral cleavage activity. Overall, these engineered Cas12a variants will enable safe precision editing in T-rich genomic regions.

1330 Current Approaches and Considerations for Viral Clearance for Cell & Gene Therapy

Kathleen O'Hagan

BioPhorum, Sheffield, United Kingdom

The assurance of viral safety in Cell and Gene Therapy (CGT) products poses a unique challenge as the inclusion of a viral vector is a key component of both *in vivo* and *ex vivo* gene therapies. Although viral clearance strategies for general biological drug manufacture and vaccine production will be applicable to these products, there will be unique challenges and considerations for cell and gene therapy manufacture. Therefore, members of the BioPhorum's Cell & Gene Therapy validation work stream have provided a publication that is intended to indicate in a single location all relevant existing guidance and advice on viral clearance for viral vectors with emphasis on Adeno-associated viral (AAV) vectors. Additionally, the team aims to highlight the unique considerations and potential options to resolve the identified challenges and recommend a 'gold standard' requirement for viral clearance for manufacture of cell and gene therapies. The aim of this publication is to help companies identify the challenges, current guidance and potential solutions for viral clearance within the cell and gene therapy field.

1331 Rapid High-Throughput Screening and Uninduced Recovery of AAV Producer Cell Lines

Dawson Ray

Berkeley Lights, Inc., Berkeley, CA

Adeno-associated virus (AAV) vectors are a powerful tool for gene therapy applications due to their ability to efficiently and specifically deliver therapeutic genes to target cells. However, current

standard manufacturing methods are not capable of producing titers necessary to treat large patient populations with systemic doses due to challenges in scaling and cost of goods (COGs). Stable producer cell lines (PCLs) are emerging to overcome these challenges, since they can be cultured at scales similar to antibody therapeutic production and do not require transfection with costly plasmids prior to harvest. Some research demonstrates additional benefits such as increased titer and better product quality, such as a higher capsid full/empty ratio, in the crude product compared to the conventional triple-plasmid, transient transfection production method. Despite these advantages, PCLs account for a small proportion of clinical-stage manufacturing techniques due to the additional development time required to engineer a PCL platform, create monoclonal lines, and assess clone productivity. This work describes a microfluidic approach to sort, assay, and recover uninduced clones from a polyclonal PCL pool of thousands in under two weeks to address the need for shorter development time of stable AAV producer cells.

1333 Elucidation of Minimal Adenoviral Helper DNA Sequences Essential for Recombinant Adeno-Associated Virus Production

Jiten Doshi[1], Jillian Staiti[1], Julio C. Sanmiguel[1], Luk H. Vandenberghe[2], Nerea Zabaleta[1]

[1]Mass Eye and Ear Infirmary, Boston, MA,[2]Cien Dias/Mass Eye and Ear Infirmary, Boston, MA

Recombinant adeno-associated viral vector (rAAV) is increasingly being used for gene therapy applications because of its non-pathogenic nature, superior safety profile and ability to transduce both dividing and non-dividing cells. The increased usage has led to a considerable surge in demand for clinical grade rAAV vectors. Triple plasmid transient transfection of HEK293 cells is the current state of the art method used to meet the demand for clinical grade rAAV vectors. This method uses three plasmids constituting of: Rep-Cap, adenoviral helper genes and ITR-flanked transgene for producing rAAV vectors. Previous research has identified adenoviral E1A, E1B, E2A, E4orf6 and VA RNA genes essential for rAAV production. Although the essential genes have been identified, the minimal helper DNA sequence sufficient for rAAV production has not been clearly established. The commonly used helper gene plasmid (referred as DeltaF6) still contains several adenoviral complete or partial coding sequences that do not play any direct role in rAAV production. Considering the GMP perspective, accurately defining genetic sequences is extremely significant and is still lacking in case of adenoviral helper genes. Although the adverse effects of the presence of these sequences is not known, they may have an impact on production quality and yield. By selective elimination process, we constructed adenoviral helper gene plasmids that are devoid of these extra sequences and our preliminary data suggests that these newly constructed plasmids positively impact rAAV production while reducing genetic footprint by ~3kb. Furthermore, our research is extending towards identification of minimal sequences (regulatory and protein-coding) of E2A, E4orf6 and VA RNA genes, essential for rAAV production. In conclusion, our work lays the foundation for accurate definition of minimal genetic components necessary for rAAV production while having a positive impact on yield and possibly in future incurring an indirect influence on the gene therapy cost.

1334 Targeted CRISPR/Cas9 Screen Identifies Superior HEK293 Cell Lines for AAV9 Production

Francis Grafton, Ryan Feitzinger, Kaylin Fisher, Lily Leveque-Eichhorn, Chris Reid, Mo Mandegar

Innovation Hub, Ascend GCTx, San Francisco, CA

There are two dominant AAV production platforms: transient transfection of mammalian cells and baculovirus infection of Sf9 insect cells. Academic and industry-led studies have shown Sf9 cells produce higher titers of rAAV, but it comes at a cost of vector quality and potency for some rAAV serotypes. Few studies have reported on systematically engineering cell systems to enhance both viral production capacity and potency. To address this, we used clonal isolation and high-throughput screening to develop a proprietary clonal suspension-adapted HEK293 cell line (AC001.230) that produces AAV9 with increased potency compared to HEK 293F cells. Through a targeted CRISPR/Cas9 screen, we identified 3 classes of targets that significantly increased AAV9 production compared to our wild-type clonal cell line. From this work, we have developed two independent suspension-adapted knockout cell lines (AC003 and AC010) that show greater than 2-fold improvement in AAV9 production capacity. We have confirmed these findings using capsid titer and vector genome quantification using a reporter construct. Studies are underway to evaluate the potency of these cell lines for production of FDA-approved therapeutic transgenes using multiple AAV serotypes and in a large-scale bioreactor system.

1335 SKG0106 is a Promising Gene Therapy Vector with Great Therapeutic Potential for the Treatment of Patients with Neovascular Age-Related Macular Atrophy

Yanqun Shu, Byron Li, Qiongqiong Ren, Peilu Li, Huimin Kong, Lumei Xiao, Bing Wu, Sijia Huang, Jinxin Deng, Zheng Luo, Dianyang Chen, Jay Hou

Skyline Therapeutics, Cambridge, MA

Introduction: Neovascular age-related macular atrophy (nAMD) is a progressive disease that leads to severe vision loss in the elderly population. Vascular endothelial growth factor (VEGF) is overexpressed in the eyes of nAMD patients and interacts with VEGFR2, resulting in abnormal blood vessel proliferation and leakage. Recombinant Anti-VEGF proteins that developed for nAMD need to be injected every 4-8 weeks for the rest of patients' lives. We have developed a proprietary AAV vector SKG0106 carrying a transgene encoding an Anti-VEGF protein Nb24. By a single intravitreal (IVT) injection, the continuously expressed Nb24 targets ocular overexpressed VEGF in the lesion area, stopping or slowing down the neovasculature growth and leakage. We tested the binding affinity of Nb24 to human rhVEGF-A and the inhibitory potency of Nb24 to block the interaction of human rhVEGF-A with VEGFR2, with Lucentis, Beovu and Eylea as controls. The therapeutic efficacy and biodistribution of SKG0106 and a reference vector were also compared in NHP CNV model. **Methods:** Binding affinity of Nb24 protein, Eylea, Beovu and Lucentis with rhVEGF-A protein were conducted by SPR or ELISA. A cell-based study was conducted to compare the inhibitory potency of Nb24 and Eylea to block the interaction of rhVEGF-A with VEGFR2 by using VEGFR2 / NFAT Reporter - HEK293

Recombinant Cell Line. In the pharmacological study using NHP CNV model, vehicle, Eylea, SKG0106 and a reference vector were administered via a single IVT injection. The efficacy of Nb24 was assessed on blocking the leakage of the fluorescein in the eyes, and the animals were sacrificed at 43 days. Tissue and blood samples were collected to evaluate the biodistribution and expression of Nb24. **Results:** The KD values of Nb24 and Eylea binding to rhVEGF-A protein were 1.98e-13M and 1.68e-13M, respectively, by SPR assay. In the functional ELISA assay, the EC50 values of Nb24 and BEOVU to rhVEGF-A were 0.21 nM and 0.29 nM, respectively. The IC50 values of Nb24 and Lucentis in blocking the binding of human VEGF-A with human VEGFR2 were 25.56 nM and 62.08 nM, respectively, by competitive ELISA assay. Nb24 and Eylea also inhibited the luciferase expression induced by human VEGF-A in VEGR2/NFAT-HEK293 reporter cells, and the IC50 values of Nb24 and EYLEA were 0.24 nM and 0.32 nM, respectively. In the pharmacological study, SKG0106 completely blocked the fluorescein leakage in the treated NHP eyes and was better tolerated than the reference vector. In addition, the biodistribution and expression levels of SKG0106 and Nb24 were meticulously assessed. The results indicated that the vector and the protein were primarily located in ocular tissues and fluids, with no detection in peripheral tissues. **Discussion and Conclusions:** Nb24 has a high affinity to VEGF-A. The protein potently blocked the interaction of human VEGF-A with its receptor VEGFR2, therefore inhibiting the signal transduction of VEGF-A, implicating that it has a potential to block the VEGF-A mediated neovascularization in the eyes of nAMD patients. Furthermore, SKG0106, an AAV vector delivering Nb24, robustly inhibited abnormal fluorescein leakage via IVT injection in the eyes of NHP CNV model (also in rabbit RNV model, data not shown), indicating that the vector can function effectively in vivo. Quantification of Nb24 by ELISA revealed that the protein was mainly located in the ocular space and was not detectable in most peripheral tissues, suggesting that the vector did not affect peripheral tissues. Importantly, SKG0106 was well-tolerated in the study and others (poster submitted separately). In conclusion, SKG0106 is a potent efficacious vector for the treatment of nAMD and has an excellent safety profile. It has the potential to be the next generation drug for the treatment of nAMD.

1336 Treatment of Recessive Dystrophic Epidermolysis Bullosa by Transplantation of Col7A1 Transgenic Tissue-Engineered Skin Graft

Xiaogang Deng[1], Weili Cong[1], Zhiming Chen[2], Zheng Zhang[1], Xian Liu[1], Wenjing Bai[1], Yijun Li[1], Xi Wang[1], Yingcun Wang[1], Qianqian Chen[1], Liwen Zhang[1], Xihui Gu[1], Yi Zhang[2], Kailiang Sun[1], Xiaoyang Wu[1], Yong Yang[2], Tian Xu[1]

[1]GeCell Therapeutics, Shanghai, China,[2]Chinese Academy of Medical Sciences and Peking Union Medical College, Nanjing, China

Recessive dystrophic epidermolysis bullosa (RDEB), caused by loss of function mutations in the COL7A1 gene encoding type VII collagen, is a devastating, often fatal, inherited blistering disorder lacking curative therapies. Epidermal stem cells/keratinocytes derived from skin tissue can be expanded, engineered with functional COL7A1 gene and further differentiated into the whole epidermis in vitro, which hold great promise for the treatment of RDEB. Here, we generated a gene-corrected tissue-engineered skin graft from RDEB epidermal stem cells via non-viral vector-Piggy/Bac transposon under the serum-free and chemical-defined culture media. The resultant COL7A1 transgenic tissue-engineered skin graft could integrate into mouse skin for a long period, restoring the COL7A1 expression without tumorigenicity risk. Moreover, clinical data from Investigator-Initiated trial (IIT) showed good efficacy and tolerance on RDEB patient indicated with partial restoration of the COL7A1 expression, good wound healing and no adverse effects after autologousCOL7A1 transgenic tissue-engineered skin graft transplantation. Collectively, our COL7A1 transgenic tissue-engineered skin grafts are promising for RDEB treatment in the future clinical study.

1337 Process is Product: High Yield NK Cell Production Processes Reshape Product Quality Profile

Zhimei Du, Gregg Nyberg

Landmark Bio, Kenilworth, NJ

Robust manufacturing production of natural killer (NK) cells has been challenging in allogeneic NK cell-based therapy. Here, we compared the impact of cytokines on NK cell expansion by developing recombinant K562 feeder cell lines expressing membrane-bound cytokines, mIL15, mIL21, and 41BBL, individually or in combination. We found that 41BBL played a dominant role in promoting up to 500,000-fold of NK cell expansion after a 21-day culture process without inducing exhaustion. However, 41BBL stimulation reduced the overall cytotoxic activity of NK cells when combined with mIL15 and/or mIL21. Additionally, long-term stimulation with mIL15 and/or mIL21, but not 41BBL, increased CD56 expression and the CD56bright population, which is unexpectedly correlated with NK cell cytotoxicity. By conducting single-cell sequencing, we identified distinct subpopulations of NK cells induced by different cytokines, including an adaptive-like CD56brightCD16- CD49a+ subset induced by mIL15. Through gene expression analysis, we found that different cytokines modulated signaling pathways and target genes involved in cell cycle, senescence, self-renewal, migration, and maturation in different ways. Together, our study demonstrates that cytokine signaling pathways play distinct roles in NK cell expansion and differentiation, which sheds light on NK cell process designs to improve productivity and product quality.

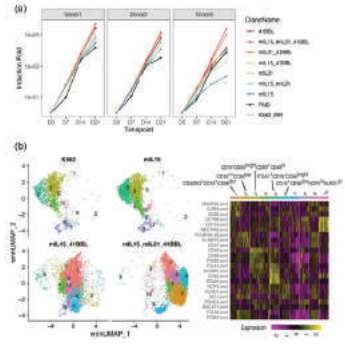


Figure 1: Developing robust NK cell manufacturing processes with high yield and desired differentiation subsets

(a) NK cell expansion fold induction (y-axis in log10 scale) from three donors with indicated process conditions.
(b) Single cell analysis. TotalSeqC panel measured RNA expression and surface protein expression, reveals 10 NK cell clusters. Different process conditions drive NK cells to follow distinct differentiation trajectories, leading to divergence in cellular composition that affect the bioactivities of the cellular products.

1338 Enhancing SaCas9 Target Specificity by Rational Directed Mutagenesis

Hind Ghezraoui, Gloria Mesa-Gil, Richard Parker-Manual, Ryan Cawood, David Brighty, Suzanne Snellenberg

OXGENE (A WuXi Advanced Therapies Company), Oxford, United Kingdom

Innovative development of the CRISPR/Cas9 system is beginning to make therapeutic gene editing a viable biomedical objective. *Staphylococcus aureus* Cas9 (SaCas9) is sufficiently compact to be packaged into AAV and is therefore commonly used for *in vivo* genome editing. However, fidelity remains a critical barrier to clinical translation. While high-fidelity SpCas9 variants have been reported, few SaCas9 variants have eliminated off-target editing, leaving cleavage error-prone repair of non-target genomic sites a critical issue to be resolved for this ortholog. Here, we developed a traffic light reporter system that examines on- and off-target editing efficiency and used it to screen rationally engineered SaCas9 variants. Using this system, we identified SaCas9 variants (variants harbouring mutations at position Y256, R314, Q414 and R654) with enhanced-accuracy and single base mismatch discrimination while maintaining robust on-target activity comparable to WT-SaCas9. Sanger and next generation sequencing allowed us to confirm dramatically reduced off-target editing (2- to 255-fold improvements) of our variants compared to WT-SaCas9 at three genomic loci. Finally, when delivered by an AAV vector our variants showed no detectable off-target activity when targeting SHLD1 locus in HeLa cells compared with WT-SaCas9. Thus, our variants could be used for genome editing applications where high precision and fidelity are required.

1339 The Unrealised Utility of Unique Molecular Identifiers ('Barcodes') as Quantifiable Reporter Elements - Demonstrations in the Study of ITR Integrity in the rAAV Vector System

Patrick Wilmott[1], Kimberly L. Dilworth[1], Suzanne Scott[1], Lawrence O. M. Wilson[2], Leszek Lisowski[3]

[1]Translational Vectorology, Children's Medical Research Institute, Sydney, Australia,[2]Australian e-Health Research Centre, Commonwealth Scientific and Industrial Research Organisation, Sydney, Australia,[3]Children's Medical Research Institute, Westmead, Australia

The need to clonally amplify AAV ITR sequences in one form or another underlies the production of all recombinant AAV vectors on the globe. These sequences are centrally involved in numerous intracellular process needed to generate and direct nonviral DNA sequences into their capsid delivery vehicles. It is therefore plainly a problem that plasmid materials used to rAAV vectors are typically heterogenous in one or both ITR loci due to poor stability in prokaryotic culture. ITR sequences have a recalcitrant reputation among rAAV researchers and we have yet to benefit from sustained efforts to understand their heterogeneity and its implications for rAAV vector manufacturing and performance. As is true for many salient challenges, the variability within and between the myriad of active rAAV production systems, and the consequences of stepwise losses and gains, call for an especially robust methodological infrastructure if durable scientific progress is to be achieved. Scientists in rAAV research have been responsible for ground-breaking methodological innovations exploiting massively parallel sequencing technology in the analysis of nucleic acid copies with mixed origins, made distinguishable and countable by short, localised sequence variations often referred to as 'barcodes', most prominently in capsid biodistribution studies. The core analytical principles are conceptually versatile and outstandingly well suited to the task of making robust and precise quantitative measurements of like nucleic acid subpopulations. Its unique quantification mechanism makes it an exceptional complement to dPCR or qPCR for molecular biologists writ large and in many contexts a superior choice. In the present study, this technique was used to track rAAV vector genomes derived from subclonal isolates of an rAAV plasmid with various deletions in the 3'ITR sequence. Barcodes were used to track these genomes and their products through multiple stages of vector synthesis in adherent HEK293 cultures, as well as in *in vivo* transduction of murine liver and skeletal muscle over an eight-week period. The study had a dual goal of showcasing the versatility and metrological capabilities of the barcode analysis strategy, as well as initiating a sustained and rigorous enquiry into the question of rAAV ITR integrity. The strategy resulted in quantitative consistency between samples replicated wholly from the point of transfection comparable with qPCR replicates of single vector samples. Reducing the fraction of intact ITRs in the transfection did not result in a clear decrease in total vector yield, though this particular study was not designed for the detection of incremental differences. Astoundingly clear by contrast were linearly predictable changes to subpopulation composition reflecting ITR-specific variations in process efficiency within a transfected culture. Intriguingly, the greatest variations in stable *in vivo* transduction were observed between vectors derived from intact plasmids, with the effects of whole deletions less prominent in comparison. These results form one component of a larger doctoral dissertation that will be submitted for examination by the time abstracts enter review.

1340 Development of UX055 AAV Gene Therapy for Cyclin-Dependent Kinase-Like 5 (CDKL5) Deficiency Disorder (CDD), a Rare Neurological Disorder

Jan Thomas Panteli[1], Julie Wei[1], Sara Potter[1], Jun Li[1], James Warren[2]

[1]Ultragenyx Pharmaceutical Inc., Woburn, MA,[2]Ultragenyx Pharmaceutical, Woburn, MA

Ultragenyx is developing UX055, a new adeno-associated viral vector-based gene therapy product for the potential treatment of Cyclin-dependent Kinase-like 5 (CDKL5) Deficiency Disorder (CDD). UX055 is a non-replicating recombinant adeno-associated virus serotype 9 (rAAV9) gene therapy containing a single-stranded DNA vector with the human CDKL5 gene under control of a neuron-specific transgene promoter. This gene therapy approach involves the transfer of a normal copy of the human CDKL5 gene to neurons, thereby enabling expression of functional CDKL5 protein for a prolonged period following a single injection via intracisternal magna (ICM) delivery, to directly address the underlying cause of the disease. Development of AAV gene therapies for rare neurological disease in pediatrics

requires a significant focus on safety and efficacy considerations in the development of the GMP manufacturing process. In developing potential gene therapy treatments for rare genetic disorders targeted to the central nervous system (CNS), careful considerations on route of administration, formulation selection, drug product concentration, dosing strategy, including dosing volume and endotoxin limits, and delivery device must all be assessed to ensure patient safety is maintained at an achievable efficacious dose. Ultragenyx has incorporated these key considerations for CNS administration into the UX055 Clinical Development Plan to achieve a safe, robust, and scalable GMP manufacturing process, that enables rapid generation of clinical material at 2000L scale to enable dosing of children with CDD.

1341 Visualizing Non-Encapsidated DNA in the Adeno-Associated Virus (AAV) Samples by Immuno-Localization Transmission Electron Microscopy (Immuno-TEM)

Magda Tušek Žnidarič, Mojca Janc, Polona Kogovšek, David Dobnik

National Institute of Biology, Ljubljana, Slovenia

Adeno-associated viruses (AAV) are most often used vectors for in vivo gene therapy. Their advantages are stability, size, as they are small enough to cross the blood-brain barrier, and generally mild immune response. In the process of preparing a clinically pure solution of the viral vectors, the detection of present impurities is very important. Among the most commonly present nucleic acid impurities are the remains of the plasmids used in transfection, and host cell DNA. Molecular assays are usually used for quantification of those impurities, however, it is still not totally clear, whether all detected impurities are encapsidated or not. We have developed and optimized an immuno-localization transmission electron microscopy (immuno-TEM) for visualization of non-encapsidated DNA in the preparation of AAV samples. Immuno-localization was performed by anti-dsDNA antibodies (ABCAM) and IgG with bound gold grains of diameter 6 nm. The method was used on the AAV samples and we were able to show the presence of non-encapsidated DNA, mostly bound to the surface of the viral particles. Some of this residual DNA remained present on the surface of the capsids even after nuclease treatment. The presence of bound, nuclease resistant, non-encapsidated residual DNA presents a challenge for purification and might pose a concern for patients.

1342 Lipid Nanoparticle Library Towards Development of Next Generation Genomic Medicines

Nikita Jain[1], Cece Nazaripour[1], Z. Chen[1], Suraj Abraham[1], L. Yee[1], Sadat Sadat[2], G. Namala[1], Helena Son[1], Sijo Chemmannur[2], K. Tickner[1], M. Anantha[1], R. Sharma[1], Sri Abbina[1], S. Thambatti[1], V. Mayya[1], E. Soon[1], J. Paquette[1], Anitha Thomas[1]

[1]Precision NanoSystems, Vancouver, BC, Canada,[2]Precision NanoSystems Inc., Vancouver, BC, Canada

Ionizable amino lipids are a major constituent of the lipid nanoparticles for delivering nucleic acid therapeutics (e.g., DLin-MC3-DMA in ONPATTRO®, ALC-0315 in Comirnaty®, SM-102 in Spikevax®). Scarcity of lipids that are suitable for cell therapy, vaccination, and gene therapies continue to be a problem in advancing many potential diagnostic/therapeutic/vaccine candidates to the clinic. Herein, we describe the development of novel ionizable lipids to be used as functional excipients for designing vehicles for nucleic acid therapeutics/vaccines in vivo or ex vivo use in cell therapy applications. We first studied the transfection efficiency (TE) of LNP-based mRNA formulations of these ionizable lipid candidates in primary human T cells and established a workflow for engineering of primary immune T cells. We then adapted this workflow towards bioengineering of CAR constructs to T cells towards non-viral CAR T therapy. Lipids were also tested in rodents for vaccine applications using self-amplifying RNA (saRNA) encoding various antigens. We have then evaluated various ionizable lipid candidates and their biodistribution along with the mRNA/DNA translation exploration using various LNP compositions. Further, using ionizable lipids from the library, we have shown gene editing of various targets in rodents. We believe that these studies will pave the path to the advancement in nucleic acid based therapeutics and vaccines, or cell & gene therapy agents for early diagnosis and detection of cancer, and for targeted genomic medicines towards cancer treatment and diagnosis.

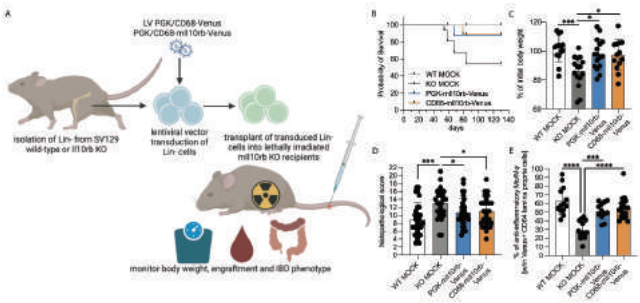
1343 HSPC Gene Therapy Using Transcriptional Targeting to Macrophages Ameliorates Very Early Onset IBD Due to IL10R Deficiency

Adele Mucci[1,2], Denise Klatt[1,2], Kayla Wright[1], Chi Yuan Zhang[1], Scott B. Snapper[3,4], David A. Williams[2], Christian Brendel[1,2]

[1]Gene Therapy Program, Dana Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, MA,[2]Division of Hematology/Oncology, Boston Children's Hospital, Harvard Medical School, Boston, MA,[3]Division of Gastroenterology, Hepatology, and Nutrition, Department of Pediatrics, Boston Children's Hospital, Boston, MA,[4]Division of Gastroenterology, Brigham and Women's Hospital, Boston, MA

Mutations in the IL-10 gene or its receptor lead to life-threatening Very Early Onset-Inflammatory Bowel Disease (VEO-IBD). Allogeneic stem cell transplant is the only curative option, leading to prolonged disease remission and survival. Because gene therapy represents an attractive therapeutic alternative, we evaluated the efficacy of two different lentiviral vector-based gene therapy approaches for IL-10 receptor beta chain (*mIl10rb*) deficiency. The first one utilizes the PGK promoter for ubiquitous transgene expression. The second approach exploits the CD68 promoter for myeloid cell-targeted transgene expression with maximum activity in mature macrophages. Gene transfer into murine *Il10rb* KO lineage negative (Lin-) HSPC restores responsiveness to IL-10 in vitro using both vectors, as measured by phosphorylation of STAT3 in differentiated macrophages. Mice treated with gene therapy or healthy donor cells (A) showed increased survival (B) and regained body weight within 20-60 days from treatment returning to more than 90% of their weight before irradiation (C), indicating amelioration of the disease, while mock-treated mice progressively lost weight dropping below 80% of their initial weight. Histopathological analysis of colon sections revealed improved tissue architecture after

gene therapy, including reduced inflammatory cell infiltration, reduced hyperplasia and improved recovery of secretory goblet cells with pathological scores significantly reduced to 10.6±3.6 and 10.8±3.7 in PGK and CD68-treated animals respectively compared to mock-treated being at 13.31±3.4 (D). On the cellular level, macrophage cell populations in the lamina propria are believed to be central to regulating immune responses. After gene therapy, we observed increased anti-inflammatory macrophages from 29.15±10.34% in mock-treated to 51.43±9.69% and 54.95±12.69% (E) and reduced proportions of inflammatory macrophages from 20.54±9.13% in mock-treated to 3.9±3.67% and 4±3.1% in lamina propria extracts in PGK- and CD68- gene therapy groups respectively. While both vectors performed comparably regarding therapeutic efficacy, we unexpectedly observed selective loss of vector copy numbers in the PGK- group. In competitive transplantation assays, we confirmed the progressive loss of cells transduced cells over time. While gene marking remained relatively stable in HSC/MPP, a pronounced 2-fold reduction of gene marking was seen in committed progenitors and mature cell lineages. This competitive disadvantage could be bypassed by expressing *mIl10rb* under the control of the CD68 promoter, which led to stable gene marking. This study demonstrates the therapeutic efficacy of a lentiviral-based HSPC gene therapy approach in a relevant mouse model of VEO-IBD, comparing constitutive and myeloid-specific promoters and demonstrating that myeloid-specificity is superior for the permanent correction of clinical features.



1344 Gene Therapy for GM1 Gangliosidosis Mediated by AAV Vector Carrying BBB-Penetrable Enzyme

Saki Matsushima[1], Sayoko Iizuka[1], Masafumi Kinoshita[2], Haruna Takagi[2], Shunsuke Iizuka[2], Kota Ohtsuki[2], Atsushi Imakiire[2], Takashi Nagashima[3], Shinichiro Okamoto[4,5], Takashi Higuchi[1], Yohta Shimada[1], Hiroyuki Hioki[4], Hiroyuki Sonoda[2], Ayako M. Watabe[3], Toya Ohashi[6], Hiroshi Kobayashi[1]

[1]Division of Gene Therapy, Research Center for Medical Sciences, The Jikei University School of Medicine, Tokyo, Japan,[2]JCR Pharmaceuticals Co., Ltd., Kobe, Japan,[3]Institute of Clinical Medicine and Research, Research Center for Medical Sciences, The Jikei University School of Medicine, Chiba, Japan,[4]Department of Neuroanatomy, Juntendo University Graduate School of Medicine, Tokyo, Japan,[5]Advanced Research Institute for Health Sciences, Juntendo University, Tokyo, Japan,[6]The Jikei University of School of Nursing, Tokyo, Japan

[Background] GM1 gangliosidosis (GM1) is a lysosomal storage disease in which mutations in the GLB1 gene result in reduced or absent lysosomal β-galactosidase (βgal) activity. βgal deficiency leads to accumulation of the substrate GM1-ganglioside in the central nervous system (CNS) resulting in progressive neurological decline. There is currently no effective treatment for the disease and in the infantile form is fatal within a few years of onset. Therefore, there is an unmet need for the development of new treatments.Although several gene therapy trials using AAV have been reported for the treatment of GM1, the effect on the CNS has been limited due to the blood-brain barrier (BBB). Recently, we reported an anti-transferrin receptor antibody (TfR) fused enzyme that could cross the BBB and formulated as Pabinafusp Alfa for MPS II enzyme replacement therapy (ERT). Here we report the combination of the TfR system and AAV mediated gene therapy to treat GM1 murine models. [Methods] AAV9s were designed to express the βgal (AAV-βgal) or the TfR-βgal (AAV-TfR-βgal) genes under the control of the mouse albumin promoter to allow the liver-specific expression.Ten-week-old male GM1 mice were intravenously injected with each of the AAVs at $1x10^{12}$ (low dose) and $5x10^{12}$ (high dose) vg/kg. The enzyme activity in serum was measured over time after administration of each virus. Twenty-three weeks after the treatment, quantification of the enzyme activity and the amount of GM1-ganglioside were performed in peripheral organs and CNS. The therapeutic effect was also evaluated by several behavioral experiments. [Results and Discussion] Biochemical quantification showed that the serum βgal activity of each AAV-treated mice was approximately 10-fold higher than that of the wild-type control at 6 weeks post-infection, and this activity was maintained throughout the experiment. In the liver and spleen, βgal activity was higher in the AAV-treated groups than in the wild type. In contrast, in the CNS, such as the cerebrum, βgal enzyme activity increased only in the TfR-βgal group, and was approximately 50% of that of the wild type in the high-dose group. GM1-ganglioside accumulation in the cerebrum, cerebellum, and hippocampus was reduced in a dose dependent manner only in the TfR-βgal treated groups. The amount of GM1-ganglioside in the group treated with low dose of TfR-βgal downed in half and with high doses of TfR-βgal was found to be at the same level as in wild-type mice. Furthermore, TfR-βgal treated mice exhibited improvements in some

of the behavioral experiments such as open field test. These results show that intravenous administration of AAV- TfR-βgal is an effective approach for the treatment of GM1 at such a low viral dose.

1345 Advanced Characterization of DNA Molecules in rAAV Vector and Plasmid DNA Manufacturing Preparations by Next Generation Sequencing

Esko A. Kautto, Apollinaire Ngankeu, Adam Davis, Frank Agbogbo, David J. Dismuke
Forge Biologics, Grove City, OH

Adeno-Associated Virus (AAV) based gene therapies have demonstrated clinical success, resulting in a growing demand for clinical- and commercial-grade manufacturing. To support this success, manufacturing highly pure AAV vector preparations at large scale and quality is a focus area for many groups. Characterization of rAAV vector and plasmid DNA for both research grade (non-GMP) and GMP-grade has relied on the gold standard of chain-terminating dideoxynucleotide (Sanger) sequencing for identity testing. However, Sanger sequencing has technical limitations and drawbacks that limit its use for comprehensive sequencing-based characterization of gene therapy products. Therefore, alternative methods that can more comprehensively screen products while increasing throughput rates and decreasing the time to results are needed for continued growth and quality oversight of drug products. Newer sequencing technologies, such as sequencing by synthesis (SBS), have become the *de facto* standard for many clinical and research applications. The massively parallel capacity exceeds that of Sanger sequencing and can provide highly accurate data. More recently, single-molecule sequencing has been commercialized by other groups that allows for full-length vector and plasmid sequencing. In our study comparing these methods, we have assessed sequencing-based methods for analyzing both plasmids and recombinant AAV gene therapy products. We compared the strengths, weaknesses, and overall utility of three sequencing platforms (from Illumina, PacBio, and ONT) for the characterization of rAAV vectors. We developed methods for optimizing sequencing workflows and analyzed vectors sequenced on all three platforms to compare their utility in various quality control tests, such as sequence identity confirmation and contaminant analysis. We then designed a comprehensive plasmid characterization and manufacturing workflow, allowing for the confirmation of plasmid identity and genome integrity, contaminant analysis. The workflow allows us to assess and ensure plasmid quality throughout the production lifecycle, leading to higher-quality products. We show that, by leveraging the strengths of sequencing-based analytics, we can accurately and unambiguously screen and characterize plasmids and vectors, both for research-grade production and GMP-grade drug products. This improves quality and production standards, resulting in high-quality and safe products with faster turnaround times.

1346 RNA-Templated Editing Using Type V CRISPR Effectors

Noah Jakimo, Fu-Kai Hsieh, Jeff Haswell, Pratyusha Hunnewell, Colin McGaw, Zachary Maben, Malini Varadarajan, David A. Scott, Tia DiTommaso, John Murphy, Gregory Hoffman
Arbor Biotechnologies, Cambridge, MA

The programmable nature of RNA-guided CRISPR nucleases stimulated a genome editing revolution, and RNA-templated systems promise to enable precise genomic repair. In this work, we present new systems for genome-primed Reverse Transcriptase-editing (RT-editing) that operate with a CRISPR Type V nuclease. Our implementation with the Type V system demonstrates precision editing within human cells mediated by optimized versions of Type V CRISPR RT-editing systems. The compact nature of the Type V effectors and their gRNAs confer advantages regarding delivery and manufacture relative to existing precision editing systems. RT-editing using a Type V nuclease has shown significant precision editing in therapeutically relevant cell types including T-cells and iPSCs, an editing profile that can be well suited to addressing specific classes of human disease. This work highlights an initial proof of concept in expanding RNA-templated editing to the broad biochemical and mechanistic diversity of Type V CRISPR systems, potentially enabling additional translational potential of RT editors.

1347 Development of AAV Mediated Gene Therapy Approach for Usher Syndrome Type 2

Anil Chekuri, Weiwei Wang, Luk H. Vandenberghe
Schepens Eye Research Institute, Boston, MA

Purpose: Usher syndrome type 2 (USH2) is the leading cause of deaf blindness with autosomal recessive inheritance. Several pathogenic mutations in *USH2A* gene have been reported to cause USH2 and non-syndromic retinitis pigmentosa (RP). Majority of *USH2A* mutations are frameshift or non-sense mutations leading to loss of function. Development of genetic therapies for USH2 have been mainly hampered due to the large size of the gene (15.6kb). USH2A protein contains several repetitive domains, and it is plausible that some of these are dispensable for its function. AAV-mediated gene supplementation is the most effective and feasible therapeutic approach making it as an expedited path for the treatment of inherited retinal degenerations (IRDs). With the aim to miniaturize *USH2A* that is amenable for AAV mediated gene therapy, we have assembled and validated *USH2A* minigene constructs for their ability to rescue ciliary phenotype in vitro. Using split intein protein trans-splicing system, we have showed the reconstitution of minigene in vitro with the potential for clinical translation in future. **Methods:** To generate *USH2A* minigenes, we used the coding sequence of the short non-repetitive region of *USH2A* as a backbone and the repetitive motifs as building blocks to generate minigenes with motif deletion in different length/region. We have evaluated the functional efficacy of these clonal minigene constructs using an *Ush2a* null Ock-1 cell line and identified a functional *USH2A* minigene (minigene-4). Immunofluorescence was performed to analyze the ciliary morphology and number in *Ush2a* null cells. Expression, localization, and reconstitution of full length minigene

was analyzed by cellular fractionation and western blotting. **Results:** Our data confirmed the expression and cellular localization of minigene-4 in periciliary region. Furthermore, our results indicate that in vitro supplementation of minigene-4 resulted in ciliary rescue in *Ush2a* null cells. Additionally, we have showed the reconstitution of minigene-4 in vitro using split intein mediated protein transplicing approach. **Conclusion:** Our results indicate the identification of functional *USH2A* minigene which can rescue ciliary defects in vitro. Our data indicate the reconstitution of minigene-4 for the utility and suitability for future clinical applications. These findings highlight the therapeutic potential of minigene-4 for treatment of USH2.

1348 Exon Skipping and Dystrophin Production with ENTR-601-45, a Novel EEV-Conjugated, Exon 45 Skip Amenable PMO in Preclinical Models of DMD

Ziqing Leo Qian, Nelsa L. Estrella, Amy N. Hicks, Ajay Kumar, Avery Guan, Sara Blake, Scarlett Cheon, Xiang Li, Anushree Pathak, Mahboubeh Kheirabadi, Patrick G. Dougherty, Wenlong Lian, Nanjun Liu, Ningguo Gao, Daniel Wang, Matthew Streeter, Mohanraj Dhanabal, Mahasweta Girgenrath, Natarajan Sethuraman

Entrada Therapeutics, Boston, MA

Duchenne muscular dystrophy (DMD) is a rare, X-linked neuromuscular disorder caused by mutations in the *DMD* gene resulting in a lack of functional dystrophin. Antisense phosphorodiamidate morpholino oligomer (PMO)-mediated exon skipping therapies have been approved for several mutations but produce only a very modest amount of dystrophin in skeletal and cardiac muscle, likely due to poor distribution to target tissues and a limited ability to escape the target cell endosome. To overcome these limitations, we designed a family of proprietary cyclic cell-penetrating peptides that form the core of our Endosomal Escape Vehicle (EEV™) technology. This EEV-PMO approach demonstrated exon skipping and dystrophin production in the D2-*mdx* mouse model of DMD. Furthermore, a single intravenous dose of ENTR-601-44 (a *DMD* exon 44 splice modulating EEV-PMO) showed durable exon skipping in skeletal and cardiac muscle in human dystrophin-expressing (hDMD) mice and non-human primates for at least 12 weeks post-dose. To further address unmet needs in the treatment of DMD, we developed an EEV-conjugated PMO for the treatment of patients amenable to exon 45 skipping therapy (ENTR-601-45). Treatment of DMD patient-derived skeletal and cardiac muscle cells with ENTR-601-45 resulted in robust exon skipping and dystrophin production. Additionally, a single IV dose of ENTR-601-45 resulted in high levels of exon skipping in hDMD mouse skeletal and cardiac muscle after 1 week. These results demonstrate the therapeutic potential of ENTR-601-45 and suggest potential for further study in patients with DMD amenable to exon 45 skipping.

1349 Selective Regulation of Gene Expression by THO/TREX Complex in Human Neuronal Cells

Chulsung Park[1], Junho K. Hur[2], Yundoo Chung[3]

[1]Department of Biomedical Science, Graduate School of Biomedical Science & Engineering, Hanyang University, Seoul, Korea, Republic of,[2]Department of Genetics, College of Medicine, Hanyang University, Seoul, Korea, Republic of,[3]Department of Life Science, University of Seoul, Seoul, Korea, Republic of

THO/TREX complex is a multi-subunit complex conserved from yeast to human. It is known to be required for transcription and nuclear export of some RNAs. Also, THO/TREX complex prevents DNA; RNA hybrid formation (R-loop) to bind nascent RNA for genome stability during transcription. When THO/TREX complex is depleted, R-loop formations are increased, and DNA of R-loop regions is damaged. In this study, we sought to understand how the depletion of THO/TREX complex leads to changes in RNA expression patterns, selective retention of RNAs in the nucleus, and changes in R-loop formation. We observed that knock out of THO/TREX complex using CRISPR led to decreased cell viability. We conducted transcriptome analyses of THO/TREX knock out cells and found that the genes with most reduced expression levels were related to cell cycle. We found that several genes which are highly expressed in the neuronal cells and are retained in the nucleus of knock out cells. Also, we found the regions of R-loop formation are increased in knock out cells. Analyses of clinical data suggested that certain single nucleotide polymorphisms in components of THO complex are associated to severe neurocognitive and growth disorder. However, the molecular mechanism of how THO/TREX complex are related to neuronal disorders is not completely understood. The results in the study suggests that the selective intervention of R-loop formation of select genes that are regulated by THO/TREX may have therapeutic effects for the neurological disease caused by depletion.

1350 Gene Supplementary Therapy in Dent's Disease Mouse Models for Sustained Therapeutic Effects

Qingqi Li[1], Manish Yadav[1], Kyung Yoo[1], Thomas Jentsch[2], Anthony Atala[3], Baisong Lu[1]

[1]Wake Forest Medical School, Winston Salem, NC,[2]2Leibniz-Forschungsinstitut für Molekulare Pharmakologie (FMP)/Max-Delbrück-Centrum für Molekulare Medizin (MDC), Berlin, Germany,[3]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC

Introduction: Type 1 Dent disease is caused by changes in chloride voltage-gated channel 5 (*CLCN5*) gene on chromosome X, which causes the lack or dysfunction of chloride channel ClC-5. Affected subjects show proteinuria and hypercalciuria, and eventually develop end-stage kidney disease. Currently there is no cure for this disease. This work aims to develop a gene therapy for Dent's disease. **Methods:** CRISPR/Cas9-mediated gene mutagenesis was used to develop a *Clcn5* mouse model with 95% of the ClC-5 coding region deleted. Lentiviral vectors were used to deliver human *CLCN5* cDNA into the kidneys of mutant mice by retrograde ureter injection. Urine was collected before and after gene delivery to examine therapeutic effects. **Results:** *1. Evident but short-term therapeutic effects were observed when mutant mice were treated at adulthood.* For the first 3 months, gene therapy greatly ameliorated Dent-like phenotypes, including decreased

urinary calcium and protein excretion. However, the therapeutic effects diminished 4 months after gene therapy, and immune responses to the transgene products most likely caused the loss of gene therapy effects. *2. Long-term therapeutic effects were observed when the mice were treated at new born*. We treated the mutant mice right after birth, when the immune systems of the mice are not developed, and observed evident and long-term (>8 months, the longest time examined) therapeutic effects. 3. *Gene therapy achieved evident therapeutic effects in Dent model mice with dysfunctional CIC-5*. About 1/3 Dent's patients are cause by missense mutations that express dysfunctional CIC-5 protein, which functions as homodimers. Two questions remain unanswered regarding gene supplementary therapy in these subjects: 1) Will the endogenous dysfunctional CIC-5 protein interfere with the function of the exogenous wild type protein and impair the effectiveness of the gene therapy? 2) Will the immune responses be less severe due to the pre-exposure of the immune system to dysfunctional CIC-5 protein? We performed gene therapy in adult mice with dysfunctional CIC-5^{E211A} and observed normalized diuresis after gene therapy. We are currently examining whether long-term therapeutic effects can be achieved in these mice. **Conclusions:** Gene therapy in new born babies could be a strategy to achieve sustained therapeutic effects in subjects affected by Dent's disease. Gene supplementary therapy is effective for Dent's disease caused by missense mutations although CIC-5 functions as homodimers.

1351 What Does the ICHQ5A Revision Mean for Your Cell & Gene Therapy Product?

Danielle DiTirro, Leyla Diaz, Anna Woodward, Armstrong Alison

Contract Testing Services, MilliporeSigma, Rockville, MD

Any Cell & Gene therapy (CGT) manufacturing strategy requires extensive characterization and release testing to assess quality, safety and efficacy of the intended final product. While national regulatory agencies (i.e., FDA, EMA, NMPA, etc.) provide guidance on the type and degree of testing expected the recommendations may not align. To address this, The International Council of Harmonisation (ICH) is a body of pharmaceutical regulatory experts tasked with harmonizing these quality and safety guidelines to benefit the global development of new pharmaceuticals. The ICH's quality chapter on viral safety testing for biological products (ICHQ5A) has recently been revised and now brings into scope a variety of CGT products. While the revision is still in draft the final revision is expected in 2024 and has significant implications to the quality control and viral safety testing accepted and expected for viral-vector, viral-vector modified and donor-derived products. This presentation provides a description of 1) the CGT products now within scope of the ICHQ5A guidance, 2) where alternative technologies can replace traditional testing strategies, 3) the additional viral clearance studies some vector products are expected to complete, and 4) how these changes will influence the viral safety testing strategies for future CGT products. Case studies will be presented to support the implications and changes expected from the ICHQ5A (R2) guidance.

1352 Development of Master iPSCs with Switchable HLA Genes by Megabase-Scale Genome Engineering

Yasunori Aizawa[1,2,3]

[1]Tokyo Institute of Technology, Yokohama, Japan,[2]Logomix,Inc., Tokyo, Japan,[3]KISTEC, Ebina, Japan

We recently developed a genome engineering platform for cells having long and complex genomes such as human cells, called Universal Knock-in System or UKiS (*Nature Communications* 13, 4219, 2022). UKiS allows for precise substitution of megabase-scale regions into synthetic genomic sequences of our design in allele-specific and scarless manners in human induced pluripotent stem cells (iPSCs); both alleles of your interest in autosomes can be efficiently modified and any unnecessary sequences such as loxP or markers are not left at the engineered regions. UKiS expands our capability of multi-functionalization of human cell for various industrial uses including therapeutic one. We are currently applying this genome engineering platform for generating new types of iPSCs for future allogeneic cell therapy, which avoids virus- and transposon-based integration of transgenes and knockout of B2M and CIITA genes. In this presentation, we introduces two types of master iPSCs that we created to deepen our understanding of HLA-mediated cell-cell interactions between immune and target cells and to develop allogeneic therapeutic cells. The first master cell (HLA-I free master iPSCs) has ~400 kb deletion of all the six HLA class I gene loci and integration of the UKiS donors at both alleles, whereas the second one (All HLA free master iPSCs) has ~1 Mb deletion of all of the six HLA class I and all the 11 HLA class II gene loci and integration of the UKiS donors at both alleles. The UKiS donor alleles can be used as landing pads which can be efficiently replaced with any gene cassettes of your interest. Here, to demonstrate usefulness of our master iPSCs, we created two different iPSC lines from HLA-I free master iPSCs by replacing both UKiS donor alleles with the following gene fragments: 1) anti-CD19 CAR & the entire gene territory of HLA-E*01:01:01 gene containing the signal sequence of HLA-A or 2) the entire gene territories of HLA-A*24:02:01, HLA-B*07:02:01, HLA-C*07:02:01 and HLA-E*01:01:01. In both cases, ~10 kb-long integration of the entire HLA gene territories including promoters and introns was effectively performed and all the integrated HLA genes were expressed in the endogenous manner because B2M was intact. These master iPSCs are advantageous in investigating the HLA-mediated interaction rules between immune cells and their target cells as well as in developing cell modality for allogeneic cell therapy and regenerative medicine.

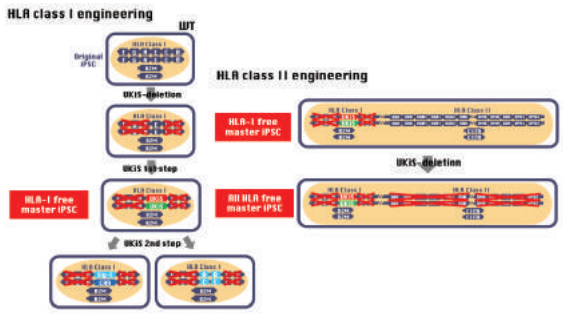


Figure. Schemes of two master iPSC development by Mb-scale genome engineering at HLA locus using Universal Knock-in System (UKiS).

1353 Development of Off-the-Shelf Hematopoietic Stem Cell-Engineered Invariant Natural Killer T Cells for COVID-19 Therapeutic Intervention

Yanruide Li

University of California, Los Angeles, Los Angeles, CA

New COVID-19 treatments are desperately needed as case numbers continue to rise and emergent strains threaten vaccine efficacy. Cell therapy has revolutionized cancer treatment and holds much promise in combatting infectious disease, including COVID-19. Invariant natural killer T (iNKT) cells are a rare subset of T cells with potent antiviral and immunoregulatory functions and an excellent safety profile. Current iNKT cell strategies are hindered by the extremely low presence of iNKT cells, and we have developed a platform to overcome this critical limitation. We produced allogeneic HSC-engineered iNKT (AlloHSC-iNKT) cells through TCR engineering of human cord blood CD34+ hematopoietic stem cells (HSCs) and differentiation of these HSCs into iNKT cells in an Ex Vivo HSC- Derived iNKT Cell Culture. We then established in vitro SARS-CoV-2 infection assays to assess AlloHSC-iNKT cell antiviral and anti-hyperinflammation functions. Lastly, using in vitro and in vivo preclinical models, we evaluated AlloHSC-iNKT cell safety and immunogenicity for off-the-shelf application. These results support the development of AlloHSC-iNKT cells as a promis- ing off-the-shelf cell product for treating COVID-19; such a cell product has the potential to target the new emerging SARS-CoV-2 variants as well as the future new emerging viruses.

1354 CRISPR/Cas9 Edited Hematopoietic Stem and Progenitor Cells for Friedreich's Ataxia

Anusha Sivakumar[1], Rafael Andres Badell-Grau[2], Rita Wan[1], Veenita Khare[3], Stephanie Cherqui[4]

[1]Pediatrics, University of California, San Diego, La Jolla, CA,[2]UCSD, La Jolla, CA,[3]UCSD, San Diego, CA,[4]University of California, San Diego, La Jolla, CA

Friedreich's ataxia (FRDA) is a multi-systemic, autosomal recessive neurodegenerative disorder caused by homozygous GAA repeat expansion mutation within intron 1 of the frataxin gene (*FXN*). The mutation reduces FXN expression, a mitochondrial protein required for iron metabolism and respiratory complex assembly. FRDA is characterized by ataxia, areflexia, sensory loss and muscle weakness but cardiomyopathy is the predominant cause of mortality. Symptoms typically begin between 5 to 15 years of age and patients are wheelchair-bound within 10-15 years of onset. Currently, there is no treatment for FRDA. We previously showed complete rescue of neurologic, muscular and cardiac complications of FRDA in YG8R mice with a single, systemic infusion of wild-type hematopoietic stem and progenitor cells (HSPC), and rescue was mediated by FXN transfer from engrafted HSPC-derived microglia/macrophages to diseased neurons and cardiac/muscular myocytes. Considering that GAA expansion mutation is seen in 98% of the FRDA patients, is in the intron region, and that overexpression of frataxin is toxic, we developed an ex *vivo* CRISPR/Cas9 gene editing approach for excising the GAA mutation in FRDA patients' $CD34^+$ HSPCs. The present study investigates the *vivo* safety and efficacy of our CRISPR/Cas9 gene editing approach in YG8s$(GAA)_{>800}$ mice model of FRDA that carries human *FXN* (h*FXN*) with >800 GAA repeats. Because the mice carry h*FXN*, we used the same CRISPR/Cas9 components of human $CD34^+$ cells. Lethally irradiated, 2-month-old mice were transplanted with or without *ex vivo* gene edited $Sca1^+$ HSPCs and analyzed 7-month post-transplant. With ~22% of editing efficiency in transplanted $Sca1^+$ HSPCs, we observed ~ 14% gene editing in blood, 4.25% in bone marrow cells, 2.67% in spleen and 4% in thymus. Gene editing in primary organs affected in FRDA such as heart and spinal cord was at ~2% and less than 1% in the brain and skeletal muscle. HSPC-derived cells abundantly increased hFXN protein across the affected tissues, particularly in the spinal cord and heart, despite the limited gene edited level in tissues. Preliminary data suggest decreased pathological cardiac hypertrophy, improved mitochondrial biogenesis, reduced inflammation, and oxidative damage in mice receiving gene-edited cells compared to mock. Altogether, the preliminary data from the *in vivo* studies demonstrate that single infusion of *FXN* gene corrected HSPCs engraft in the bone marrow niche to become a reservoir of healthy cells that can integrate into the injured organs for local and systemic delivery of frataxin protein.

1355 Re-Dosing of Liver-Targeted AAV within and across Clades in Mice: Effects of Neutralizing Antibodies and Vector-Specific Factors

Daisy Huynh[1], Laura Van Lieshout[2], Gordon Sears[1], Emma Kerimo[1], Monicah Kivaa[3], Deiby Faulkner[1], Jamie Ritondo[1], Arnold Sengooba[1], Arthur Tzianabos[3], Teresa Wright[2], Omar Francone[3], Mijeong Kim[1]

[1]Immunology, Homology Medicines Inc., Bedford, MA,[2]Homology Medicines, Bedford, MA,[3]Homology Medicines, Inc., Bedford, MA

Recombinant adeno-associated virus (rAAV)-based gene therapy is a promising approach for the treatment of inherited diseases. Since AAV vectors are non-replicating, episomal transgene expression may wane over time, either due to dilution as a result of organ growth in pediatric patients or in response to tissue injury or inflammation. The formation of neutralizing antibodies (nAb) and memory T cells in response to the initial AAV vector treatment may limit the ability to re-dose. Here, we demonstrate that re-dosing among different AAV clades, including Clade F, is possible as evaluated in the the pre-clinical Pah^{enu2} mouse model of phenylketonuria, which has elevated serum phenylalanine (Phe). Two studies are described below. In the first study, the first cohort of mice were dosed intravenously (I.V.) at 5E+12 vg/kg with an AAVHSC15 (Clade F) vector expressing phenylalanine hydroxylase (PAH) and then after 4 weeks, the mice were re-dosed I.V. at 5E+13 vg/kg with AAV5, AAV6 (Clade A), AAV8 (Clade E), AAV9 (Clade F), AAVHSC15 (Clade F), or AAVHSC17 (Clade F) vectors expressing Factor IX (FIX). Blood levels of FIX and Phe were measured throughout the study from Day 3 through Day 98. Mice in the first cohort (initially dosed with 5E+12 vg/kg of AAVHSC15-PAH) showed reduction of serum Phe to normal levels as early as Day 3, and subsequent re-dosing at 4 weeks with 5E+13 vg/kg of AAV5-FIX, AAV6-FIX, or AAV8-FIX (non-Clade F vectors), resulted in successful expression of human FIX in plasma. Re-dosing with a Clade F vector did not lead to normalization of serum Phe levels. In the second cohort, mice were dosed I.V. at 5E+13 vg/kg with AAV5, AAV6, AAV8, AAV9, AAVHSC15, or AAVHSC17 vectors expressing FIX. After 16.6 weeks,

the mice were re-dosed I.V. at 5E+13 vg/kg with AAVHSC15 expressing PAH. Blood levels of FIX and Phe were measured throughout the study from Day 3 through Day 203. Mice in the second cohort (initially dosed with 5E+13 vg/kg of AAV5-FIX, AAV6-FIX, AAV8-FIX, AAV9-FIX, AAVHSC15-FIX or AAVHSC17-FIX) showed expression of human FIX as early as Day 3, and subsequent re-dosing with 5E+13 vg/kg of AAVHSC15-PAH resulted in normalization of serum Phe in mice first dosed with the non-Clade F vectors (AAV5/6/8-FIX) but not with a Clade F vector expressing FIX (AAVHSC15/17-FIX). Interestingly, only one of three mice dosed first with 5E+13 vg/kg AAV8-FIX achieved complete Phe correction. We hypothesized that this variability in the liver transduction efficiency of the second dose could be due to the presence of AAV vector genome (vg) from the first dose. The vg analysis on the terminal liver samples demonstrated that the mouse that exhibited Phe correction post-dose with a Clade F vector had the lowest FIX vg as compared to the mice that did not exhibit Phe correction. In a subsequent study, the interval between the first and second AAV doses was shortened from 16 weeks to 4 weeks. When mice were re-dosed with AAVHSC15-PAH at 4 weeks post-AAV8-FIX dose, every mouse showed successful expression of FIX whereas mice showed little to no reductions in Phe level. These data indicate that the presence of a high level of vg residing in the cells from the first dose in a given timeframe could itself inhibit the transduction of the second dose, which is an additional mechanism beyond the presence of nAb. These data support the potential for successful AAV re-dosing across AAV clades while also highlighting the importance of the initial dose's potency. It is possible that re-dosing with certain clades is dependent not just upon nAb activity, but on the capacity of the liver to be transduced when high levels of AAV vgs are present. Further studies are warranted for translation into human patients.

1356 Toward an *In Vivo* Approach to Knock-Out the HIV Co-Receptor CCR5 in Hematopoietic Stem Cells Using HDAd Vectors Expressing Base Editors

Anna Anderson, Aphrodite Georgakopoulou, Andre Lieber, Chang Li

University of Washington, Seattle, WA

One of our goals is HIV prophylaxis/therapy by knocking out the HIV co-receptor, CCR5, in hematopoietic stem cells (HSCs) by a simple, cost-efficient, one-day treatment that involves only intravenous injections and could therefore be applicable in resource-poor countries in which AIDS is endemic. Knock-out of CCR5 in HSCs would be passed on to all HSC progeny cells including HIV target cells in the blood and HIV reservoir tissues (gastro-intestinal/genital tracts, brain…). It would therefore block the infection and spread of the virus and lead to a life-long cure/protection. We tested three strategies to knock out CCR5 expression: i) creating a premature stop codon, ii) eliminating the ATG start codon and iii) mutating the splice acceptor sites to skip CCR5 exons. To achieve this, we used base editors (BEs), enzymes that are capable of introducing precise cytidine or adenine substitutions with minimal occurrence of undesired DNA changes at the target site. Here we employed an advanced adenine base editor version (ABE8e) and an early version of cytidine base editor (CBE). ABE8e and CBE are targeted to their desired sites in the genome by a single guide RNA (sgRNA) expressed from a polymerase III U6 promoter. The editing machinery was delivered with helper-dependent adenovirus vectors (HDAd5/35++) that efficiently infect HSCs in vitro and in vivo. Two guide sequences were screened for each of the three strategies. In a CCR5-positive cell line (TZM-bl), transfection with these six all-in-one base editor plasmids generated 13-50% target site editing rates measured by Sanger sequencing. The percentage of CCR5 knockout was 2.93 to 39%. One guide sequence targeting the start codon (referred to as sgSTOP2) and one guide sequence that creates a premature stop codon (referred to as sgR5-1) were demonstrated to mediate higher on-target editing rates as well as CCR5 down-regulation and therefore were selected for downstream experiments. Using miRNA-regulated gene expression and suppression of BE expression with anti-CRISPR inhibitors, we successfully produced two HDAd5/35++ vectors: HDAd-ABE8e-sgSTOP2 and HDAd-CBE-sgR5-1. We then tested the two vectors in TZM-bl cells transduced with increasing vector doses (0-5000 viral particles/cell). Overall, editing rates were higher with the ABE8e vector than with CBE vector, which was most likely due to the higher activity of ABE8e. After infection with HDAd-ABE8e-sgSTOP2 vector at 5000 vp/cell, more than 50% of CCR5 alleles were edited. The percentage of CCR5-negative cells did not differ as much between the two vectors as the editing rate indicating that HDAd-CBE-sgR5-1 blocks CCR5 gene expression more efficiently. Next, we studied whether CCR5 base editing in TZM-bl cells protects them from HIV infection. TZM-bl cells are susceptible to HIV infection (through CD4 and CCR5) and infection can be measured as a function of a reduction in Tat-induced luciferase reporter gene expression. Compared to cells without HDAd transduction, the luciferase activity was 40% and 95% lower in HDAd-ABE8e-sgSTOP2 and HDAd-CBE-sgR5-1 infected cells. This indicates that the HDAd-CBE-sgR5-1 vector is more efficient in blocking HIV infection. The next steps are to further improve this vector by using more active CBE platforms, e.g. TadA-derived CBEs and inserting a $MGMT^{P140K}$ expression cassette that would allow for in vivo expansion of edited HSCs and HSC progeny in animal studies. The improved vectors will then be tested in primary human PBMCs and HSCs that were differentiated into T-cells.

1357 Development of Genome-Modified Generation M (GenM) AAVrh74 Vectors with Improved Transgene Expression in a Mouse Muscle Cell Line and in Primary Human Skeletal Muscle Cells

Jakob Shoti[1], Keyun Qing[1], Arun Srivastava[2]

[1]University of Florida, Gainesville, FL,[2]University of Florida College of Medicine, Gainesville, FL

We have previously reported that the distal 10-nucleotides (nts) in the AAV2 D-sequence share partial homology to the consensus half-site of the glucocorticoid receptor-binding element (GRE), and that replacement of the distal 10 nts with a full GRE site leads to generation Y (GenY) ssAAVrh74 vectors that mediate up to 6-fold higher transgene expression in primary human skeletal muscle cells compared with those containing the wild-type (WT) D-sequence (*Mol. Ther.*, 30: 237-238, 2022). In the current study, we evaluated if this approach could be extended to include muscle cell-specific transcription factors. The myoblast determination protein 1 (MyoD) and myocyte enhancer factor 2 (MEF2C) have been previously shown

to cooperate in transcription activation during myogenesis (*Mol Cell Biol*., 18: 69-77, 1998). We designed a novel AAV-ITR in which the entire D10-sequence (**Figure 1A**) was replaced with MyoD and MEF2C binding site sequences (**Figure 1B**). Additionally, we replaced part of the stem A-domain to be complementary to the MyoD sequence to ensure that the rerminal resolution site (*trs*) was conserved to allow AAV Rep-mediated resolution, rescue, replication, and packaging. Encapsidation of these genomes containing a muscle cell-specific promoter (MHCK7)-driven hrGFP espression cassette into AAVrh74 capsids led to the development of Generation M (GenM) AAVrh74 vectors. The transduction efficiency of WT and GenM MHCK7-hrGFP AAVrh74 vectors was evaluated in differentiated C2C12 mouse myotubules. As can be seen in **Figure 1C**, the GenM AAVrh74 vectors averaged ~3-fold increased transgene expression compared with that from the WT AAVrh74 vectors (p<0.01). These vectors were further evaluated in differentiated primary human skeletal muscle cells, and shown in **Figure 1D**, mediated ~2-fold increased transgene expression (p<0.01), compared with that from the WT AAVrh74 vectors. These data suggest that genome-modifications involving the AAV D-sequence is a useful strategy to achieve improved transgene expression from ssAAV vectors. Studies are currently underway to optimize the design of the GenM ITR involving an orientation that is speculated to be more conducive of positive transcription factor interaction. Additional studies are also planned involving packaging of GenM genomes into capsid-modified NextGen AAVrh74 vectors leading to the generation of optimized GenM vectors (Opt^{M}) AAVrh74 vectors for high-efficiency transduction as well as augmented transgene expression in murine skeletal muscles following systemic delivery, which has implications in the optimal use of these vectors in the potential gene therapy of muscular dystrophies in humans.

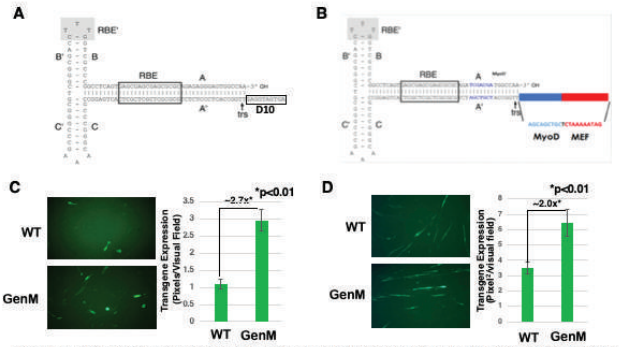

Figure 1: Schematic structures of the WT **(A)** and GenM **(B)** AAV-ITRs. Transduction efficiency of WT and GenM AAVrh74 vectors in differentiated mouse C2C12 **(C)** and primary human skeletal muscle **(D)** cells. Cells were transduced with WT and GenM AAVrh74 vectors at 37°C for 2 hrs, and transgene expression was visualized under a fluorescence microscope following differentiation. Data were quantitated using the NIH ImageJ software.

1358 Gene EXPRESSion Platform: Enabling Early Potency Development and Stability Assessment

Eugenia Fandunyan

Oxford Biomedica Solutions, Bedford, MA

Measuring the potency of your product throughout development is critical for program success. While assays that measure the biological activity of your product are the gold standard for potency assay measurements, these assays typically have long lead times, necessitating an alternative strategy to support early development. We have established a platform gene expression assay to bridge this gap. This poster will walk through the experiments necessary to build a robust gene expression platform assay. The result is a platform assay with a short development timeline for new products (<1 month) that can be used in the early phases of product development. This platform assay can be used to support initial assessments, including candidate screening, scale up comparability, and formulation studies. This poster will also highlight data from a stability indicating assessment that demonstrates that the gene expression platform assay is the most stability indicating assay in our toolbox demonstrating a loss of potency and stability before other analytical methods.

1359 Oncolytic Cell-Based Therapy to Overcome Virus Inactivating Immune Response in Small Cell Lung Cancer Models

Dae Hong Kim[1], Jackie Lara[1], Erika Yap[1], Linda Flores[1], Marisa McDonald[1], Gary Ngai[1], Emma Eriksson[2], Dan Raz[1], Rachael G. Mooney[1], Angelica SI Loskog[3], Karen S. Aboody[1], Mohamed Hammad[1]

[1]Beckman Research Institute of the City of Hope, Duarte, CA,[2]LOKON Pharma, Uppsala, Sweden,[3]Uppsala University, Uppsala, Sweden

Small cell lung cancer (SCLC) is one of the most detrimental cancers. There are about 30,000 new cases of SCLC patients in the US each year with 80-90% death rates in 2 years. Although many patients experience significant tumor response to their first chemotherapy, these fast-growing cancer cells soon develop chemo-resistance and rebound in a couple of years. Considering these trends, more effective treatments for the SCLC patients are urgently needed including Oncolytic virotherapy (OV). However, OV is found to be restricted by the immune response. Fortunately, with the development of oncolytic virus packaged in stem cells, oncolytic virotherapy now can successfully overcome the barrier of immune response and deliver robust and safe way of tumor killing in patients. In our studies, we loaded clinically safe neural stem cell line (NSCs) with tumor selective oncolytic adenovirus LOAd703 (NSCs. LOAd703) and studied their tumor killing activities in vitro and in vivo. This conditionally replication-competent oncolytic adenovirus was released from NSCs and then selectively replicated within tumor cells and destroyed them in situ via direct lysis. Once lysed, the cells then freed additional viral particles that continued to infect neighboring tumor cells. In addition, this oncolytic virus (OVs) induced tumor cell lysis and consequently exposed the tumor antigens that promoted immune recognition of tumor cells and caused the cascading effect of tumor-killing activities in patients. Through in vitro and in vivo models of humoral immunity-mediated virus inactivation, NSCs. LOAd703 maximized the effect of OV by multiplying the infectious virus particles. They also minimized the blockage of the therapeutic effect of oncolytic viruses (OVs) by the immune barriers and thus protected the OVs from immune mediated inactivation and therefore enhanced the anti-cancer effects.

1360 Engineering AAV Vectors for Sustained Gene Expression in Dividing Cells

Travis Blaze McMurphy[1], Andrew Park[2], Patrick Heizer[1], Crystal Card Bottenfield[1], Yasuhiro Ikeda[2], Suddhasil Mookherjee[1]

[1]Cell Therapeutics and Viral Technologies, AstraZeneca, Gaithersburg, MD,[2]AstraZeneca, Gaithersburg, MD

Recombinant adeno-associated viral vectors are powerful tools for *in-vivo* gene delivery. Their non-pathogenic nature, low immunogenicity, and ability to persist episomally without genomic integration make them ideal for gene therapies targeting terminally differentiated cells. However, episomal DNA is lost rapidly in dividing cells, and transgene expression is susceptible to promoter silencing. To overcome these limitations, we designed AAV vectors capable of maintaining themselves episomally in mitotic cells by incorporating scaffold/matrix attachment region (S/MAR) and replication initiation (IR) sequences into an expression cassette. A panel of S/MAR or S/MAR and IR-containing constructs were screened *in-vitro* in Hek293 cells for their ability to sustain gene expression in dividing cells. Eight promising constructs were further evaluated *in-vivo*. CMV-Luciferase reporter constructs were packaged into AAV9 capsid and administrated intravenously to C57/BL6 mice for *in-vivo* assessment. Luciferase reporter gene expression was monitored periodically and terminally by IVIS imaging for 130 days. Three constructs were observed to be superior to controls in maintaining gene expression *in-vivo.* A replicated analysis with three constructs resulted in the identification of single most promising construct. Further analysis was done to map the critical region in the vector for its functionality. A bait-capture deep sequencing study revealed no significant difference in the genomic integration pattern between samples injected with the control vector and the S/MAR-IR vectors. Our modifications to the AAV expression cassette enhanced and sustained expression in dividing cells and *in-vivo,* laying the foundation to expand the utility of AAV vectors

1361 A Cell-Based Potency Method to Assess the Impact of Forced Degradation Methods on AAV Drug Product

Lakmini Wasala[1], Amanda Bries[1], Robert Damitz[2], Vickie Dowling[1], Wayne Yount[3]

[1]Analytical Development, Kriya Therapeutics Inc., Research Triangle Park, NC,[2]Kriya Therapeutics, Morrisville, NC,[3]Kriya Therapeutics, Redwood City, CA

Identification of degradation pathways is a critical aspect of AAV drug product development. A cell-based assay was developed to assess AAV drug product potency and was used to elucidate degradation pathways affecting transduction and protein expression. The vector was subjected to multiple forced degradation processes, high temperature, low pH, high pH and oxidation. Forced degraded vector was tested for capsid titer and viral genome (vg) titer analysis by Gyros and droplet digital PCR, respectively. To determine the transduction efficiency of the force-degraded vector, HEK293 cells were transduced at different MOI's. At 52h post-transduction, the cells were immunostained with a product specific antibody and analyzed by flow cytometry. Gyros assay was performed to quantify the protein expression. All samples were compared to a reference vector lot, non-force degraded. High temperature treatment had no or minimal impact on vg titer and capsid titer, but the vector potency was significantly reduced compared to the reference. Acidic and alkaline pH's reduced the vg titers and capsid titers similarly. The vector potency was significantly reduced for acidic pH treated vector compared to the alkaline pH treated vector. The impact of oxidation on vector was highest when vector was treated with a higher percentage of peroxide, which reduced the vg titer, capsid titer, and vector potency compared to the reference. This assay provides essential insight into the impact of common degradation pathways on AAV drug product potency.

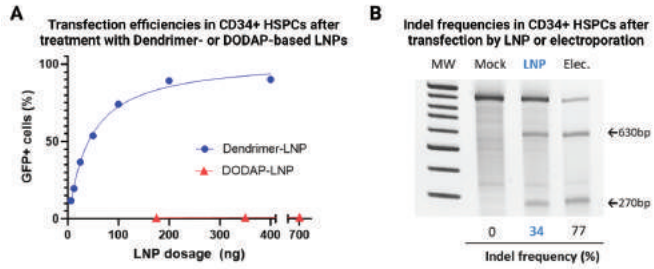
1362 Dendrimer-Based Lipid Nanoparticles for Efficient, Low-Toxicity Gene Editing of Human Hematopoietic Stem and Progenitor Cells

Anirudh Rao[1], Richard Smith[1], Olga Vasalatiy[2], Kelly Lane[2], Rolf Swenson[2], Andre Larochelle[1]

[1]Cellular and Molecular Therapeutics Branch, National Heart Lung and Blood Institute (NHLBI), National Institutes of Health (NIH), Bethesda, MD,[2]Chemistry and Synthesis Center, NHLBI, NIH, Bethesda, MD

Current gene therapy approaches to the treatment of hematopoietic diseases primarily rely upon *ex vivo* delivery of therapeutic transgenes in human hematopoietic stem and progenitor cells (HSPCs) via integrating retroviral vectors. In contrast, CRISPR/Cas9 technology enables precise editing of cellular genomes, obviating concerns associated with retrovirus-mediated insertional mutagenesis. Additionally, systemic delivery of CRISPR/Cas9-based gene editing cargoes would circumvent the complexity of the *ex vivo* process and the toxicities of preparative regimens necessary for HSPC engraftment after *ex vivo* gene correction. Accordingly, we sought to develop a lipid nanoparticle (LNP)-based strategy for high-efficiency delivery of CRISPR/Cas9 components with minimal cytotoxicity in *ex vivo*-cultured human HSPCs, with the long-term goal of adapting this strategy to targeted delivery of ligand-conjugated LNPs to HSPCs *in vivo*. A recent investigation (*Adv. Mater.* 33, 2006619 [2021]) identified the ionizable amino dendrimer lipid 4A3-SC8 with advantageous properties for gene editing applications. In this study, we characterized LNP formulations based on 4A3-SC8 dendrimers for the ability to deliver various RNA cargos to human HSPCs *in vitro*. As proof-of-concept, LNPs were first encapsulated with GFP-encoding mRNA transcripts at a dendrimer to core lipid molar ratio of 38.5:30:30:1.5 (Dendrimer:DOPE:Cholesterol:DMG-PEG) and validated by physicochemical characterization. Encapsulation using total lipid concentrations of 4-6 mM in the organic phase in combination with low-pH, aqueous phase RNA solutions (nucleic acid concentration 50 ng/uL; pH 3.5) was determined to yield an optimal particle diameter (130-170 nm) and polydispersity index (< 0.2), as well as high encapsulation efficiency (50-90%). To assess the transfection efficiency, LNPs encapsulating GFP mRNA were applied to primary human HSPCs *in vitro,* and GFP expression was quantified by flow cytometry. A dose-response experiment demonstrated highly efficient GFP expression (>80% GFP+ cells) at LNP dosages ≥200 ng per 2.5 x 10e5 cells, with minimal associated cytotoxicity (viabilities 85-99%). In contrast, as characteristically observed with lipid-mediated transfection approaches in primary hematopoietic cells, human HSPCs were refractory to transfection based on LNPs formulated by substituting 4A3-SC8 with the commonly used ionizable cationic lipid DODAP (Fig. A). Moreover, colony forming unit assays of HSPCs transfected

with GFP mRNA-encapsulated 4A3-SC8 LNPs demonstrated preserved colony forming potential. In additional experiments, dendrimer-based LNPs were individually formulated with Cas9 mRNA and single guide RNA (sgRNA) targeting the human AAVS1 locus. Importantly, indel frequencies of up to 34% were achieved in human HSPCs with a single application of Cas9/sgRNA encapsulated LNPs, providing a tractable alternative to electroporation-mediated transfection approaches known to impair HSPC long-term repopulating function *in vivo* (Fig. B). Overall, dendrimer-based LNPs provide a novel low-toxicity and promising platform for human HSPC gene therapy. Future experiments will examine the ability of antibody-conjugated LNPs to target HSPCs *in vivo*.



1363 Peptide Discovery Pipeline Identifies Presented Neoepitope Targets for T Cell Receptor-Gene Therapies

Elise C. Wilcox[1], Miranda C. Lahman[1], Chenwei Lin[2], Lisa A. Jones[2], Philip R. Gafken[2], Roland K. Strong[3], Stanley C. Lee[4], Aude G. Chapuis[1]

[1]Program in Immunology, Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]Proteomics Shared Resource, Fred Hutchinson Cancer Center, Seattle, WA,[3]Division of Basic Science, Fred Hutchinson Cancer Center, Seattle, WA,[4]Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, WA

T cells genetically modified to express a high affinity T cell receptor (TCR) specific for tumor cell-expressed antigens and adoptively transferred into patients have considerable potential for the treatment of cancer. However, substantial uncertainty remains as to which peptide/HLAs should be targeted. To identify protein-derived peptide/HLA pairs that are specific to and continuously expressed on tumor cells, we have developed a pipeline for identifying protein-specific peptides presented across HLA types (ARTEMIS). Briefly, HLA-specific single chain dimers (SCDs), which have a His-Tag instead of the transmembrane domain allowing secretion of the peptide/HLA in the supernatant, are co-transduced with target proteins for downstream mass-spectrometry analysis. We used this versatile platform to identify HLA-specific peptides resulting from point mutations in p53 and alternative splicing events induced by a mutation in SRSF2. Mutations in tumor protein 53 (TP53 or p53) occur in 40-50% of cancer patients. These mutations prevent the function of p53 which controls cell division and cell death and are "driver" mutations on which cancer cells rely for continued proliferation. The top 9 mutations make up approximately 30% of tested cases, making them an ideal target. Previous reports have shown that most common p53 mutation results in presentation of a targetable non-self peptide on HLA-A2. To validate this targeting strategy and expand the eligible patient population, peptide/HLA pairs must be identified for additional mutations across several HLAs. Using the ARTEMIS system, we were able to rapidly screen for mutation-derived peptides bound to 5 different HLAs (HLA-A1, A2, A3, A11, and A24) which cover greater than 90% of phenotype of the US. With SCDs, each individual HLA can be interrogated separately without the complex result deconvolution required by traditional immunoprecipitation methods. Mutations in SRSF2 (Serine and arginine Rich Splicing Factor 2), a protein involved in pre-mRNA splicing, are prevalent across multiple types of high-risk myeloid neoplasms. Experiments with cell lines modified to express a SFSR2-P95H/+ mutation showed mis-regulation of hundreds of splicing events potentially exposing a large pool of unique, tumor-associated peptides that could be targeted by TCR gene therapy. ARTEMIS allows us to directly assess HLA-specific presented neoepitopes resulting from alternate splicing events. We identified thousands of peptides exclusive to mutant P95H/+ K562s cells for HLA-A11 and A24. Next, computational analysis of RNA sequencing data from wild type and P95H/+ cells narrowed the list of peptides to those which resulted from alternate splicing events, against which T cell lines can be developed. This technique can easily be adapted for other cell lines and mutations associated with RNA or protein processing. To validate the identified peptides, we screened for T cell lines against these shared peptide/HLA pairs and assessed their ability to recognize and kill cell lines carrying the p53 or SRSF2 mutations. This work demonstrates a robust pipeline to discover novel HLA/peptide pairs specific to mutated, cancerous cells and thereby extend the reach of engineered TCR-based therapies.

1364 Therapeutic Genome Editing for Tay-Sachs Disease with a Simple CRISPR-Cas9 System

Joshua E. Hung[1,2], Reid A. Brewer[1,2], Evgueni A. Ivakine[1,2]

[1]Genetics & Genome Biology Program, The Hospital for Sick Children, Toronto, ON, Canada,[2]Department of Physiology, University of Toronto, Toronto, ON, Canada

Introduction: Tay-Sachs disease is a fatal neurodegenerative disorder caused by pathogenic mutations of *HEXA* encoding the α-subunit of Hex-A, an αβ heterodimer that catalyses degradation of GM2 ganglioside in the brain and spinal cord. The most prevalent *HEXA* mutation is a tetranucleotide duplication in exon 11 (1278insTATC), which completely inactivates Hex-A, leading to rapid neurological deterioration from infancy as undegraded GM2 accumulates in neuronal lysosomes. In an engineered cell model, we investigated whether CRISPR-Cas9-induced double-stranded breaks (DSB) within the 1278insTATC duplication could induce productive DNA repair outcomes that restore Hex-A activity. In addition to precise duplication removal via microhomology-mediated end joining (MMEJ) repair following DSB lesions at or near the duplication junction, we posited that therapeutic editing could also occur by non-homologous end joining (NHEJ) insertions/deletions (indels) that re-establish the mRNA open reading frame. Indel-reframed mRNA would yield a Hex-A variant with amino acid alterations yet may still possess physiologically sufficient function. **Methods:** Canonical PAM sequences for natural Cas9 endonuclease species that would permit cutting at or near the 1278insTATC duplication junction were not

present. Thus, we sought to circumvent PAM constraints by using the SpRY nuclease, an engineered variant of *Spy*Cas9 with heavily relaxed PAM requirements. SpRY nuclease activity and concomitant editing were evaluated for 18 guide RNAs (gRNA) targeting all 9 positions on both DNA strands spanning the 1278insTATC duplication. **Findings:** 16 of 18 gRNAs did not yield detectable nuclease activity or generated no therapeutically relevant reframing indels. The gRNA targeting 1nt (nucleotide) downstream of the junction on the antisense strand yielded precise deletion of the duplication at ~19% of all detected alleles alongside a range of non-corrective indels together comprising 67% of all alleles, including 2-nt insertions that theoretically reframe the mRNA found at 22% frequency. Another gRNA, targeting 4nt downstream of the junction on the sense strand, generated a heterogeneous population of non-corrective indels, including a 1-nt deletion at 37% frequency, which is expected to also produce an mRNA-reframed product. Hex-A enzyme activity was fluorometrically assayed using the synthetic Hex-A substrate 4-MUGS to examine how generated editing outcomes ultimately correspond to functional recovery. Perfect deletion of the duplication resulted in full restoration of wildtype Hex-A activity levels. In contrast, three variants with either the 1-nt deletion or 2-nt insertion exhibit little to no recovery of Hex-A function. Western blotting indicates these indels do not lead to high expression of a Hex-A polypeptide, suggesting low tolerance for amino acid perturbations like insertions and substitutions resulting from mRNA-rescuing indels. **Conclusions**: We hypothesise that the lack of therapeutic effectiveness of the reframed mRNA (mutant α-subunit) is due to improper folding leading to reduced stability. Our ongoing mutagenesis work aims to create a larger collection of variants from the 1278insTATC mutation that contain 1-nt deletions putatively restoring mRNA expression. To validate our hypothesis, we will use RT-PCR to confirm the expression of the reframed mRNA and western blot analysis to assess the misfolding issue. The results of this study will provide further insight into the therapeutic potential of CRISPR-Cas9/NHEJ interventions targeting the 1278insTATC mutation.

1365 A Human-Ready Regulated AAV9/mini*MECP2*-miRARE Gene Therapy (TSHA-102) Improves Survival, Weight, and Behavior after Intracerebroventricular (ICV) Dosing in the Neonatal Knockout Rett (RTT) Mouse Model

Kome Okposo[1], Emdadul Haque[1], Chanchal Sadhu[2], Suyash Prasad[2], Mary Newman[2], Michael W. Lawlor[3], Steven J. Gray[4], Sarah E. Sinnett[4]

[1]Department of Research and Development, Taysha Gene Therapies, Dallas, TX,[2]Formerly of Department of Research and Development, Taysha Gene Therapies, Dallas, TX,[3]Diverge Translational Science Laboratory, Milwaukee, WI,[4]Department of Pediatric, University of Texas Southwestern Medical Center, Dallas, TX

Background: Methyl-CpG binding protein 2 (MeCP2) is an X-linked transcription regulator whose loss-of-function and duplication respectively mediate equally severe neurodevelopmental disorders: Rett syndrome (RTT) and MECP2 duplication syndrome. To create an effective gene therapy for RTT while mitigating the risk of overexpression-related side effects, researchers developed a miR-Responsive Autoregulatory Element (miRARE). Insertion of miRARE into the 3'UTR of a mini*MECP2-myc* viral genome was previously shown to improve the therapeutic profile of mini*MECP2-myc* gene therapy. More recently, researchers published an abstract describing the efficacy of TSHA-102, a clinical-candidate version of the AAV9/mini*MECP2*-miRARE vector (lacking the *myc* epitope tag), after intrathecal administration at postnatal day 7 (P7), P14, and P28. To illustrate the full therapeutic potential of TSHA-102, we also evaluated efficacy after neonatal administration. Methods: TSHA-102 was assessed in a pharmacology study in neonatal *Mecp2*$^{-/Y}$ KO mice. This study evaluated the efficacy of TSHA-102 dosing via intracerebroventricular (ICV) route at Postnatal Day 2 (PD2). Efficacy parameters evaluated included body weight (BW), survival, and phenotypic scores (Bird score). Results: ICV administration of TSHA-102 in P2 KO mice at a dose of 8.8 x 10^{10} vg/mouse [Human Equivalent Dose, (HED) 2.86 x 10^{14} vg/participant (Emami et al 2018)] significantly improved survival, BW, and behavior. The median survival for vehicle-treated KO mice was 8.1 weeks. While the longest-lived vehicle-treated KO mouse survived to only 13.3 weeks, ~50% of the treated KO mice survived to 36 weeks of age, the age at which monitoring was ended. TSHA-102 significantly improved BW in KO mice compared to vehicle treated KO mice. Bird score, a composite measure of six different phenotypes, was significantly improved in TSHA-102-treated KO mice. TSHA-102 significantly delayed the average age of onset for severe clasping from approximately 7 to 21 weeks and severely abnormal gait from approximately 8 to 20 weeks. Conclusions: TSHA-102 treatment at 8.8 x 10^{10} vg/mouse extended survival significantly in neonatal *Mecp2*$^{-/Y}$ males, improved weight, improved their overall phenotypic score, and delayed the age of onset for severely abnormal limb clasping and gait.

1366 Scalable Ultra-Purification of Adeno-Associated Viral Vectors - A Novel Standard to Boost Transduction Efficacy and Potency for Cardiac Gene Therapy Development

Andreas Jungmann[1], Eric Meinhardt[2], Philip Schlegel[2], Martin Busch[3], Patrick Most[1]

[1]Molecular and Translational Cardiology, University Hospital Heidelberg, Heidelberg, Germany,[2]Cardiology, University Hospital Heidelberg, Heidelberg, Germany,[3]Heidelberg University Hospital, Heidelberg, Germany

Introduction: A high transduction efficacy and potency of AAV-based cardiac gene therapies is key for the clinical translation in which hereditary and acquired cardiac disorders will be targeted. In light of a rather poor cardiac transduction capability of utilized AAVs that led to the premature termination early clinical AAV-based heart failure trials, ultrapure AAV vectors with superior biological potency may be advantageous for the translatability of pre-clinical cardiac gene therapy programs as it allows, e.g., for greater therapeutic efficacy with lower dosages and lower production needs. **Hypothesis:** We hypothesized that our developed affinity chromatography (AC) based purification system will not only increase AAV recovery but also potency of the vectors due to greater purity. **Approach and Results:** Using the same rAAV9 vector input quantity from the upstream HEK-293 production, the AC-based purification enabled an approximately 13-fold greater vector genome copy (vgc) recovery than a density gradient (DG)-

based purification, using iodixanol. Subsequent mass spectrometry analysis demonstrated ultrapure AAV9 vectors as a result of an AC purification (93.24% rAAV9 protein content vs. 6,76% contaminating proteins) whereas corresponding DG preparations resulted in highly contaminated vectors (5.49% rAAV9 protein content vs. 94,51% contaminating proteins), which mirrored results by in-gel silver staining and electron microscopy analysis of both groups. Biological potency of AC- and DG-purified AAV9 vectors towards cardiac transduction efficacy was then determined by systemic tail vein injections of $4{\cdot}10^{11}$, $4{\cdot}10^{12}$ or $4{\cdot}10^{13}$ vgc/kg body weight (BW) of either AC- or DC-purified AAV9-EGFP in C57BL/6 mice (n=8 each group). AC-purified AAVs achieved a significantly higher cardiac transduction efficacy at every dosage level assessed by comparative bulk myocardial viral vector DNA, EGFP RNA and EGFP protein level analysis after 2 weeks by PCR, RT-PCR and immunoblotting. Therapeutic potency was examined using a recently published novel regulatable target system for chronic heart failure, namely the intravenous applicable relaxin (RLN) ligand and RLN regulatable relaxin receptor 1 (RFXP1). Informed by our in vivo cardiac transduction dose-efficacy curve, a dosage of $2{\cdot}10^{12}$ vgcs of either AC- or DG purified AAV9-RXFP1 vectors were systemically injected via the tail vein and the cardiac contractile performance increase was captured after 2 weeks in mice of both groups. Of note, 10 minutes after RLN administration, the rise in LV $+dp/dt_{max.}$ was already significantly greater in the AC- than the DG-vector treated group (AC: 13594+/-1972 vs. DC: 9822+/-801 mmHg/s; n=8 per group, $p<0.01$) and the plateau effect was likewise significantly greater for AC than DG-purified rAAV9-RXFP1. **Conclusion:** Our data clearly promote AC-based AAV purification as a novel standard for cardiovascular basic and translational research. Higher consistency in results, higher therapeutic effects and superior biological potency, e.g., in murine models as demonstrated here, can be expected from higher production yields of ultrapure AAVs already at comparably low clinical dose regimens.

1367 Standardization of Flow Cytometric Measurement on Antigen Expression

Jerilyn Izac[1], Ningchun Xu[1], Linhua Tian[2], Heba Degheidy[3], Paul Patrone[4], Anthony Kearsley[4], Lili Wang[5]

[1]Biosystems and Biomaterials, NIST: National Institute of Standards and Technology, Gaithersburg, MD,[2]National Institute of Standard and Technology (NIST), Gaithersburg, MD,[3]U.S. Food and Drug Administration, Silver Spring, MD,[4]NIST: National Institute of Standards and Technology, Gaithersburg, MD,[5]National Institute of Standards and Technology, Gaithersburg, MD

Objectives: Cell-based therapies have emerged as a novel approach to treat cancer and other conditions. Response to antigen-based immunotherapy relies upon the level of antigen expression by tumor cells and decreasing levels of antigen expression can be an early indicator of developing resistance to therapy. For targeted immunotherapy in B-cell malignancies, several studies have highlighted the crucial role of quantifying surface CD19 using flow cytometry in providing guidance for proper selection of therapies. However, the lack of adequate reference materials to control assay variability and the complexity of the cytometer instrumentation, in addition to the existence of numerous cytometer platforms have resulted in a lack of comparable and quantitative CD19 expression analysis across different laboratories and hence, no establishment of clinical cut-off values for CD19 targeted therapies. This study is designed to evaluate CD19 expression as potential reference materials and provide an assessment of their suitability to support the development of CD19 reference standards. **Methods:** CD19 expression measurements were made (1) using QuantiBrite PE calibration with the use of unimolar CD19 PE conjugate and (2) a linearity calibration combined with a single point scale transformation with CD4 as the reference marker. This investigation is an extension of our previous study in which commercially available human peripheral blood mononuclear cells (PBMC) made by three different manufacturers, PBMC-A, PBMC-B, and PBMC-C were evaluated for their suitability as cell reference materials for CD19 expression analysis (https://doi.org/10.1371/journal.pone.0248118). Here, a synthetic CD19 B cell material was tested and compared with PBMC-A. The synthetic CD19 B cell material had three levels of CD19 expression. Variables potentially contributing to the differences in CD19 expression, CD19 PE reagent, lot of PBMC-A and synthetic CD19 cell material, operator, two cytometer platforms, and quantification approaches were considered in the material evaluation. **Results & Conclusions:** Mean values of CD19 ABC (antibodies bound per cell) and associated uncertainty are measured for both PBMC-A and synthetic CD19 cell material. The sources of uncertainty from the variables tested and their relative contributions are identified and analyzed. Full understanding of the uncertainty contributions leads to areas of improvement for production of high-quality and robust reference standards for comparable and quantitative expression measurement using flow cytometry. Antigen quantification assays using ABC values and reference materials evaluated in the study enable the result comparability and establishment of clinical cut-off values, and ultimately provide vital information on patients receiving antigen directed immunotherapy.

1368 A Novel Microenvironment Regulated System CAR-T (MRS.CAR-T) for Immunotherapeutic Treatment of Esophageal Squamous Carcinoma

Lihong Wang[1], Yangyang Wu[1], Xiaosa Wang[1], Jingjing Wang[1], Wenping Zhou[1], Jianyao Wang[1], Haoran Guo[1], Yifan Wu[1], Na Zhang[1], Sujuan Fang[1], Lufang Zhang[1], Xuanyu Hu[1], Yuanyuan Zhao[1], Jinxin Miao[2], Zifang Zhang[1], Louisa S. Chard[3], Nicholas R. Lemoine[3], Zhenguo Cheng[1], Yaohe Wang[3]

[1]National Centre for International Research in Cell and Gene Therapy, Zhengzhou University, Zhengzhou, China,[2]Academy of Chinese Medical Sciences, Henan University of Traditional Chinese Medicine, Zhengzhou, China,[3]Centre for Cancer Biomarkers & Biotherapeutics, Barts Cancer Institute, Queen Mary University of London, London, United Kingdom

The poor efficacy and safety of chimeric antigen receptor T cell therapy due to on-target of tumour effects remain a challenge for application of this therapy in human solid tumors. We designed a tumor microenvironment (TME)-regulated system chimeric antigen receptor T (MRS.CAR-T) which can be selectively activated in the solid TME. B7-H3 was selected as the target antigen for esophageal carcinoma. A conditionally regulated element comprising a human serum albumin

(HSA) binding peptide and a matrix metalloproteases (MMPs) cleavage site was inserted between the 5' terminal signal peptide and single chain fragment variable of the CAR skeleton. HSA binds with an HSA binding peptide effectively, physically preventing systemic activation of MRS. CAR-T cells against B7-H3. MMPs in the TME cleave HSA at the MMP cleavage site and expose the B7-H3 binding site, leading to MRS.CAR-T activation in the TME. The anti-tumor function of MRS.B7-H3.CAR-T cells was better compared to classical B7-H3.CAR-T cells, but reduced IL-2 and IFN-γ expression was noted, reducing the potential for adverse reactions associated with cytokine release. Additionally, MRS.B7-H3. CAR-T produced more effector memory T cells compared to classical CAR-T cells. MRS.CAR-T represents a novel strategy to improve the efficacy and safety of CAR-T therapy in solid tumors.

1369 Development of Cell-Based Assay to Study AAV Vector-Mediated Activation of Innate Immune Responses

Alan Baer[1], Nirjal Bhattarai[2]

[1]FDA/CBER, Silver Spring, MD,[2]FDA, Silver Springs, MD

Host immune responses against adeno-associated viral (AAV) vectors pose a safety risk to patients and can reduce therapeutic efficacy of AAV gene therapy. To date, activation of both the innate and the adaptive immune responses against AAV vectors have been well documented in humans during AAV vector-mediated gene therapy. While various strategies have been proposed to reduce the immunogenicity of AAV vectors, due to a lack of predictive in vitro models, these strategies are often tested in animals, which can be time consuming, costly, and often findings do not translate to humans. Thus, development of reliable in vitro assays to assess immune responses against AAV vectors prior to animal studies may help in identifying effective immunomodulatory strategies in a rapid and cost-effective manner. AAV-mediated activation of Toll-like receptor 9 (TLR9) signaling has been shown to contribute to development of both the innate and the adaptive immune responses against AAV vector. However, assessment of AAV-mediated activation of innate immune signaling in vitro has been challenging. Here we screened various human and murine cell lines, along with primary human cells, to assess activation of innate immune signaling pathways by AAV vectors containing single-strand (ss) or self-complementary (sc) genomes. We found that most human and murine cell lines, which are responsive to TLR4, TLR7 or TLR9 ligands or type-I interferons (IFNs), did not respond to AAV vectors. However, primary human monocytes and a THP-1 (human monocyte) cell line were activated to varying degrees by AAV vectors. Interestingly, TLR9 inhibition alone did not completely rescue AAV mediated cellular activation, suggesting TLR9-indepependent mechanisms may also play a role. To further characterize AAV mediated responses in both THP-1 and monocytes, a cytokine array was performed, which identified several novel cytokines upregulated by AAV vectors. Currently, studies are underway to validate identified inflammatory cytokine(s) as a marker of innate immune activation during AAV vector-mediated gene therapy and develop a novel, cost-effective in vitro assay to assess innate immune responses against AAV vectors.

1370 Efficient Messenger RNA Delivery for Universal *Ex Vivo* Modification of Natural Killer Cells for Cancer Immunotherapy

Stefania Douka[1], Lisa Brandenburg[1], Monica Raimo[2], Jan Spanholtz[2], Enrico Mastrobattista[1], Massimiliano Caiazzo[1]

[1]Pharmaceutics, Utrecht University, Utrecht, Netherlands,[2]Glycostem Therapeutics, Oss, Netherlands

Natural killer (NK) cells are innate immune effectors that have remarkable potential in eliminating cancerous and virally infected cells via germline-encoded surface receptors. NK cells have gained attention as an alternative to T cells for adoptive cell therapy (ACT), as they can be generated off-the-shelf from allogeneic sources and have shown favorable outcome and lower toxicity *in vivo*. *Ex vivo* engineering of NK cells to express (chimeric) activating receptors or to knock-out inhibitory regulators is a promising therapeutic strategy, as it can enhance their tumor targeting and infiltrating properties. Although viral vectors, including retro-and lentiviruses, have been extensively used to stably deliver genetic material, NK cells are notoriously difficult to transduce. Alternative transfection strategies, such as electroporation, show low cell recovery. Additionally, previous research has shown that electroporated NK cells change their phenotype after treatment. Therefore, advancements in gene delivery strategies are pivotal to achieve efficient NK cell engineering in a safe and regulatory-compliant manner. Our research focuses on the evaluation of mRNA delivery to NK cells via lipid nanoparticles (LNPs). Using microfluidics, we formulated a series of eGFP-mRNA-LNPs altering the cholesterol analogue while tuning the total flow rate and the volume ratio, and we administered them to the NK cell line KHYG-1 to assess both their transfection efficiency and toxicity. All formulations were characterized by size distribution and ζ-potential. Notably, we observed that replacing cholesterol with its natural analogue β-sitosterol resulted in significantly higher transfection efficiency 24 hours after delivery (from 70% to 84%), with a 38-fold increase in the mean fluorescence intensity (MFI) of eGFP expression measured via flow cytometry. Additionally, a decrease in the total flow rate from 11 to 9 mL/min and an increase in the lipid to mRNA volume ratio from 1:1.5 to 1:3 resulted in higher transfection efficiency (93%) and a 4-fold rise in the MFI. Regarding the transfection-related toxicity, treatment with LNPs maintained high cell viability (>99%). When compared to electroporation, transfection via our optimized mRNA-LNP formulation was superior on both KHYG-1 NK and Jurkat T cells. Transfection efficiency of KHYG-1 cells was 92% for LNPs vs 85% for electroporation, with a 35-fold increase in MFI for LNP. Similar results were observed in Jurkat cells, with a transfection efficiency of 95% vs 63% and a 54-fold difference in MFI. Importantly, mRNA delivery with the optimized LNP formulation was also successful in cord-blood derived primary NK cells, GTA002 from Glycostem Therapeutics, resulting in 75% eGFP-positive cells compared to 57% from electroporation. Collectively, these results indicate that, upon optimization, LNPs are an efficient non-toxic mRNA delivery method for *ex vivo* modification of NK cells and show superior transfection potential to electroporation.

1371 Editing the Core Region in HPFH Deletions Alters Fetal and Adult Globin Expression for Treatment of β-Hemoglobinopathies

Vigneshwaran Venkatesan[1,2], Abisha Crystal Christopher[1], Manuel Rhiel[3,4], Manoj Kumar K Azhagiri[1,2], Prathibha Babu[1,2], Kaivalya Walavalkar[5], Bharath Saravanan[5], Geoffroy Andrieux[6,7], Sumathi Rangaraj[1], Saranya Srinivasan[1], Karthik V. Reactivation of fetal hemoglobin (HbF) is the commonly adapted strategy to ameliorate β-hemoglobinopathies. However, the continued production of defective adult hemoglobin (HbA) limits the HbF tetramer production affecting the therapeutic benefits. Here, we evaluated deletional hereditary persistence of fetal hemoglobin (HPFH) mutations and identified an 11 kb sequence, encompassing Putative Repressor Region (PRR) to β-globin Exon-1 (βE1), as the core deletion that ablates HbA and exhibits increased HbF production compared to HPFH or other well-established targets. The PRR-βE1 edited hematopoietic stem and progenitor cells (HSPCs) retained the genome integrity and the engraftment potential to repopulate for long-term hematopoiesis in immunocompromised mice producing HbF^{+ve} cells *in vivo*. Further, PRR-βE1 gene editing is feasible without *ex vivo* HSPC culture. Importantly, the editing induced therapeutically significant levels of HbF to reverse both sickle cell disease (Fig.1 A, B) and β-thalassemia major phenotypes (Fig.1 C, D). These findings imply that the PRR-βE1 gene editing patient HSPCs could lead to improved therapeutic outcomes for β-hemoglobinopathy gene therapy.

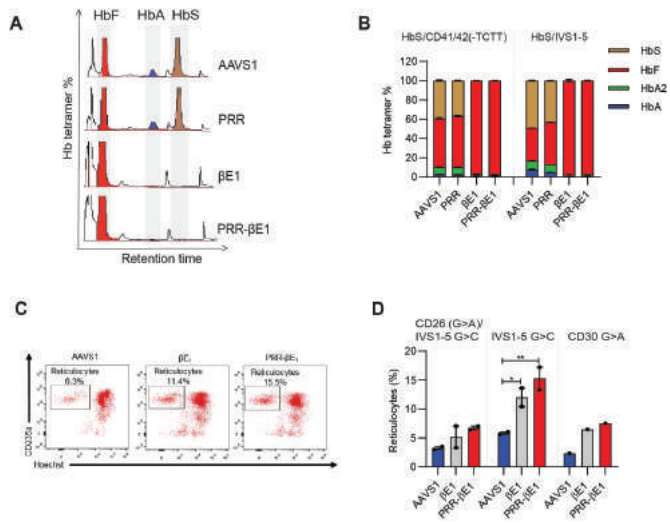

Figure 1 - PRR-βE1 gene editing reverses sickle and β-thalassemia disease phenotype

A. Representative variant HPLC chromatogram showing HbA, HbF and HbS peaks.
B. Proportion of hemoglobin tetramer - the gene edited sickle cell disease patient HSPCs were differentiated into erythroblasts and the hemoglobin tetramers were analyzed by variant HPLC. Donor = 2, n = 2.
C. Representative flow cytometry plots of reticulocytes marked by CD235a+/Hoechst-.
B. Percentage of reticulocytes generated from gene edited β-thalassemia patient HSPCs. Donor = 3, n = 2.

1372 CD20 CAR T-Cells Reversibly Ablate B-Cell Follicles in a Nonhuman Primate Model of HIV Cure

John K. Bui, Carly E. Starke, Nikhita H. Poole, Blake J. Rust, Keith R. Jerome, Hans-Peter Kiem, Christopher W. Peterson

Fred Hutchinson Cancer Center, Seattle, WA

Introduction: Chimeric antigen receptor (CAR) T cells targeting B cell antigens such as CD19, CD20, and BCMA have generated considerable successes for treatment of B cell malignancies, including lymphomas that are overrepresented in people living with HIV-1 (PLWH). HIV leads to broad immune dysfunction especially in the T cell compartment, which persists even after viral replication is suppressed by antiretroviral therapy (ART). The potency of CAR T-cell therapies for lymphomas and other cancers in PLWH therefore represents a critical gap in knowledge. To address this, we compared the safety and efficacy of CD20 B-cell-specific CAR T cells in our well-established nonhuman primate (NHP) model of ART-suppressed HIV-1 infection. We focused on the impact of $CD20^+$ B cell depletion in tissue-associated B cell follicles (BCFs), key structures where HIV persists on suppressive ART, and which serve as useful markers for CAR T-cell function in solid tissues. The goals of this study were to quantify the impact of suppressed infection on CD20 CAR T-cell function, and conversely to understand how B-cell-targeting CAR T cells may affect persistent HIV infection.
Methods: Using an adapted HIV-like virus (SHIV) to model HIV infection in NHP, we quantified the kinetics, magnitude, and impact of CD20 depletion in 2 groups of 4 pigtail macaques including uninfected and SHIV-infected, ART-suppressed cohorts. NHP CD20 CAR T cells were manufactured *ex vivo* and infused

following low-dose cyclophosphamide conditioning with anti-IL6 prophylaxis. Flow cytometry, PCR-based methods, and immunohistochemistry were used to track CAR T-cell expansion, target cell depletion, and BCF architecture at longitudinal time points *in vivo*. **Results:** CD20 CAR T-cells were well-tolerated and highly functional in both uninfected and SHIV/ART animals with transient B-cell aplasia and reversible BCF ablation observed in both cohorts. SHIV infection was associated with greater sensitivity to lymphodepletion by cyclophosphamide, slower B-cell recovery (uninfected median 46 days, SHIV/ART median 70 days), and lower platelet counts after CAR T-cell therapy. CAR T-cells expanded and trafficked to primary and secondary lymphoid tissues in uninfected and infected animals, but did not appreciably impact SHIV-infected cells in blood and tissues. Across 27 distinct compartments including peripheral blood, no effective reduction of viral reservoirs was observed. CD20 CAR T cells dramatically disrupted BCF architecture in secondary lymphoid tissues; these structures reformed concurrent with rebound in peripheral $CD20^+$ B-cell counts. **Conclusions:** Our findings support the safety and feasibility of CAR T-cell therapies with additional monitoring in PLWH with a B cell malignancy. Although disruption of BCFs in lymph nodes and other secondary lymphoid tissues was insufficient for virus eradication in our HIV model, combinations of B-cell directed CAR T-cells and anti-HIV effector therapies may expose and more efficiently target infected cells in this previously inaccessible reservoir. We also demonstrate that CD20 CAR T-cells reversibly disrupt BCFs, a finding with important implications for CAR T-cell function in solid tissues and for HIV cure approaches. Collectively, these studies validate our promising NHP model of CAR T-cell function, opening numerous avenues to optimize cutting-edge treatments for infectious diseases and cancer.

1374 Synthetic Pathway Activators (SPAs) Increase Engineered T-Cell Potency and Persistence through Tunable STAT Activation

Anzhi Yao, Thomas J. Gardner, Beatriz Millare, Ashley Cass, Suchismita Mohanty, Jeremy Chen, Alma Gomez, David DeTomaso, Lionel Berthoin, Meng Lim, Azalea Ong, Vince Thomas, Nicholas Quant, Aaron R. Cooper, Levi Gray-Rupp, Angela C. Boroughs, W. Nicholas Haining

ArsenalBio, South San Francisco, CA

Clinically effective adoptive T cell therapy for the treatment of solid tumors requires robust T cell expansion, persistence, and potency. The Janus-kinase signal transducer and activator of transcription (JAK-STAT) pathway plays a critical role in governing T cell activation and differentiation, making it a potential axis for programming an effective T cell response against solid tumors. To exploit this potential, we synthetically engineered a library of proteins, termed Synthetic Pathway Activators (SPAs), that can constitutively drive STAT signaling at variable levels without external cytokine input. We have developed several classes of SPAs driving different STAT pathways, including what we term Class I SPAs (SPA.I), which primarily drive the STAT3 pathway. When constitutively expressed in our integrated logic-gated circuit (AND-gated) CAR-T (ICT) cells, SPA.I results in significant enhancements in T-cell potency and expansion evidenced by both in vitro assays and in vivo models. In our repetitive stimulation assays, where T cells are challenged with tumor cells every 2 days for over 2 weeks, SPA.I results in dramatically improved tumor cell clearance. Across various mouse xenograft models, SPA.I-expressing ICTs reach at least 6-fold improved tumor growth inhibition. RNAseq and ATACseq analysis indicate notable changes to gene expression profiles in T cells expressing SPA.I, with maintenance of T cell stem-like phenotypes, and restricted chromatin accessibility at enhancers of various exhaustion marker genes. Importantly, despite significantly increased levels of expansion, ICTs equipped with SPA.I show no signs of cytokine-independent growth. In addition, ICT cells expressing different classes of SPAs show appropriate and rapid contraction following tumor clearance in-vivo. The SPA platform thus allows tuning of T cell biology to engineer T cell therapies with increased anti-tumor potency and cellular persistence.

1375 Characterization of Factors That Influence the Yield and Quality of AAV Produced Using HSV Co-Infection

Xiaofei E, Brian Collins, Ben Wright, Lauren Peters, Sviatlana Rose, Carl Morris, Sharon McGonigle

Solid Biosciences, Charlestown, MA

Adeno-associated virus (AAV)-mediated gene therapy is a promising clinical approach for the treatment of genetic diseases. Systemic AAV delivery used for gene therapy treatment of muscle diseases such as Duchenne muscular dystrophy requires a high viral dose to deliver the therapeutic transgene to as many muscle fibers as possible. Continual improvements to increase both rAAV quality and yield are thus desired to manufacture sufficient material for clinical use. In this study, several factors were assessed for their impact on rAAV yield and quality in a herpes simplex virus (HSV) production system.Recombinant HSV constructs for the gene of interest (rHSV-GOI) and Rep-Cap (HSV-RC) were used for dual infection of HEK293 cells, cultured in synthetic medium A in a model shake flask system. rAAV yield was measured using GOI ddPCR and quality was estimated through measure of mis-packaged HSV DNA by ddPCR. Additional characterization of relevant proteins from both virus and host cells was also performed to increase understanding of the rAAV production process.Several factors including HEK293 cell density, shaker speed, and the sequence of infection of the two viruses influenced rAAV yield. Multiplicity of infection (MOI) and cell culture medium were identified as the factors with most significant impact on rAAV yield and quality. When the MOI ratio of rHSV-GOI to rHSV-RC was increased 4-fold, both yield and quality were improved. To better understand the MOI-driven rAAV production improvements, ICP0 in HEK293 lysate post-infection was measured as a surrogate for HSV infectivity and demonstrated a clear difference between the two viruses with rHSV-GOI infection of HEK293 cells significantly less efficient than rHSV-RC at the same MOI. Increasing the ratio of rHSV-GOI to rHSV-RC 4-fold achieved similar infection levels of both viruses which correlated to the increased rAAV yield and significantly reduced mispackaged HSV DNA. These data suggest that equal levels of rHSV-GOI and rHSV-RC infection are necessary to facilitate optimal rAAV production and highlight the utility and relevance of characterizing the biology of the HSV infection process. In a study where various culture media were compared, a significantly higher rAAV yield with minimal mispackaging was observed in medium B versus A (used in MOI studies). Improved rAAV

yield and quality in medium B correlated to increased and equivalent levels of ICP0 for both rHSV viruses. Together, these findings highlight the complexity of rAAV manufacture using HSV and identify several factors that significantly influence yield and quality. In particular, the relationship between culture medium and HSV infectivity with its consequent impact on MOI for rAAV production was unexpected and illustrates the value of studies that characterize the biology of HSV infection and rAAV production.

1376 Safety and Preliminary Efficacy of PCRX201, an Intra-Articular Gene Therapy for Knee Osteoarthritis: A Phase 1, Open-Label, Single Ascending Dose Study

Stanley Cohen[1], Alan Kivitz[2], Lynell Klassen[3], Masato Nakazawa[4], Dennis Parenti[4], Mary DiGiorgi[4], Roy Winston[4]

[1]Metroplex Clinical Research Center, Dallas, TX,[2]Altoona Arthritis and Osteoporosis Center, Duncansville, PA,[3]University of Nebraska Medical Center, Omaha, NE,[4]Pacira Biosciences, Inc., Tampa, FL

Purpose: Interleukin-1 (IL-1) is believed to be an important driver of inflammation, pain, and disease progression in osteoarthritis (OA). Preclinical data have suggested that gene therapy may offer long-term expression of therapy at the disease site. PCRX201 is a helper-dependent adenovirus that expresses the IL-1 receptor antagonist gene and is designed to be activated by a nuclear factor κB-responsive promoter during inflammation. Herein, we report preliminary phase 1 study results of the safety and efficacy of PCRX201 in knee OA. **Methods:** This proof-of-concept, open-label, single ascending dose study (NCT04119687) enrolled adults (30-80 years old) with moderate-to-severe knee OA. Additional inclusion criteria included Western Ontario and McMaster Universities Osteoarthritis Index pain score (WOMAC-A) ≥4.0 and ≤9.0, Kellgren-Lawrence grades 2 through 4, and prior failure of ≥2 other treatments for OA. The first cohort of participants received ultrasound-guided intra-articular PCRX201 injection to the knee joint at ascending doses (low, mid, and high). The subsequent cohort received pretreatment with intra-articular methylprednisolone 40 mg right before PCRX201 administration at the same doses. Safety was the primary endpoint, including adverse event (AE) monitoring, repeated index knee assessments, and laboratory evaluations. Efficacy was assessed as the change from baseline in pain (WOMAC-A). The current data represent preliminary observable data with no imputations for missing values. **Results:** Thirty-six participants were enrolled and treated in each cohort (nonpretreated, pretreated) between March 2020 and December 2021. Low-, mid-, and high-dose PCRX201 was administered to 12, 16, and 8 patients, respectively, in the nonpretreated cohort and to 13, 15, and 8 participants, respectively, in the pretreated cohort. Index knee effusions considered related to PCRX201 were dose-dependent (50%, 56%, and 100% by ascending dose in the nonpretreated cohort and 31%, 27%, and 63% by ascending dose in the pretreated cohort). Most index knee AEs were treated with rest, ice, acetaminophen, and synovial fluid aspiration. One patient in the pretreated cohort (mid-dose) experienced severe pain during PCRX201 administration, resulting in early injection termination. Pain improvement from baseline was noted for dose groups in each cohort as assessed by WOMAC-A scores (Figure 1). The proportion of participants experiencing a 50% reduction in WOMAC-A from baseline over time is shown in Figure 2. **Conclusions:** PCRX201 was generally well-tolerated, with a decreased severity and incidence of index knee events in the steroid-pretreated cohort versus the nonpretreated cohort. Preliminary efficacy results suggested considerable pain improvement across all doses.

1377 A New Benchtop System for Simple and Versatile Introduction of Macromolecules into Human Lymphocytes and CD34+ Cells by Microfluidic Squeezing

Eric Ouellet[1], Manreet Chehal[1], Gil Paik[1], Elinor Binson[1], Tina Liao[1], Phillip Chau[1], Grace Kuo[1], Jessie Yu[1], Ulrike Lambertz[1], Kevin Chen[1], Maisam Dadgar[2], Jacquelyn L. S. Hanson[2], Jonathan Gilbert[2], Armon Sharei[2], Bob Dalton[1], Allen C. Eaves[3], Sharon A. Louis[1], Andy I. Kokaji[1]

[1]STEMCELL Technologies, Inc., Vancouver, BC, Canada,[2]SQZ Biotechnologies, Watertown, MA,[3]Terry Fox Lab, Vancouver, BC, Canada

Motivated by the need to address formidable challenges in the study and treatment of diseases, the cell therapy field has recently experienced explosive growth in the availability of novel molecular tools for engineering new cellular functions. A key aspect in the development of these applications is the requirement to efficiently deliver these molecular tools to living cells. The increasing complexity and variety of bio-active molecules that need to be delivered continue to push the limits of traditional methods of intracellular delivery. Indeed, these methods often restrict the range of compatible cargos that can be delivered to primary cell types, particularly with viral transduction and lipid-based transfections. Although electroporation represents a widely used non-viral alternative, significant and unwanted genetic dysregulation that can lead to altered downstream cell biology is often overlooked. In order to address these challenges, we developed the CellPore™ system. This system enables direct cytosolic introduction of molecules to a variety of primary cell types at research scales. The CellPore™ system relies on a mechanism of controlled cell deformation within microfluidic channels under specific flow conditions. This Cell Squeeze® process creates transient disruptions in the plasma membrane that enable direct cargo entry into the cytosol in a gentle fashion. We developed a straightforward workflow to determine optimal cargo delivery conditions to human unactivated T cells and CD34+ hematopoietic stem and progenitor cells (HSPCs). This workflow comprises several steps that include cell isolation, fluorescent cargo preparation for delivery across a range of system pressures, followed by viability and delivery efficiency measurements. Once identified, these optimized parameters were subsequently applied to co-deliver eGFP and mCherry mRNA as well as delivering CRISPR-Cas9 gene editing ribonucleoproteins (RNP) that target the β2 Microglobulin (B2M) gene. Editing of B2M resulted in loss of the major histocompatibility complex (MHC) class I surface molecule. Functional studies of edited cells were also performed in order to determine the impact of the CellPore™ system on overall cell quality. A colony-forming unit (CFU) assay was performed to ascertain the impact of gene editing on HSPC lineage commitment and showed minimal perturbations to their function. Further, we demonstrated that the CellPore™ system did not affect the resting phenotype of unactivated T cells, measured by the absence of both CD69 activation marker expression (0.65 ± 0.1%; mean ± SD; n = 6) and IL-2 cytokine secretion (0.10 ± 0.09 pg/mL; n = 3). This was contrary to results obtained by electroporation that resulted in large increases of both CD69 expression (38.4 ± 4.8%; n = 6) and IL-2 secretion (77.6 ± 23.4 pg/mL; n = 3), independent of T cell receptor (TCR) engagement. Importantly, results also demonstrated the ability of CellPore™-edited unactivated T cells to undergo similar activation and expansion compared to unmanipulated samples. These results underscore the important considerations that need to be made when choosing a suitable intracellular delivery method in order to engineer appropriate cellular function, while limiting unwanted genetic perturbations. The CellPore™ system offers significant advantages over traditional delivery methods in this capacity, in a simple and familiar workflow that can be easily integrated as part of cell therapy research programs.

1378 Brainstem Delivery of a Novel AAV Serotype for Sensorineural Hearing Loss Provides Efficient Gene Transfer Across the Cochlear Spiral of Adult Rats

Jerusha Naidoo[1], Yin Ren[2], Eric Bielefeld[3], Hsuan-Chih Kuo[2], Matthew Avenarius[4], Nathan McFarland[1], Allison Clark[1], Matthew T. Rocco[5], Meika Travis[1], Victor Van Laar[1], Krystof Bankiewicz[6]

[1]Neurological Surgery, The Ohio State University, Columbus, OH,[2]Otolaryngology – Head and Neck Surgery, The Ohio State University, Columbus, OH,[3]Speech and Hearing Science, The Ohio State University, Columbus, OH,[4]Pathology, The Ohio State University, Columbus, OH,[5]Neurological Surgery, The Ohio State University, Powell, OH,[6]The Ohio State University, Columbus, OH

Introduction: Noise and chemotherapy-induced hearing loss (NIHL; CIHL) are common types of sensorineural hearing impairment in humans. Cell types that are most vulnerable are hair cells (HCs) and spiral ganglion neurons (SGNs). Gene therapy approaches have focused mostly on restoration or protection of HCs. Such strategies may be effective for hearing loss affecting HCs (e.g. otoferlin mutations), but are unlikely to be effective against NIHL and CIHL. SGNs are the major information pathway from the cochlea to the brain, and their integrity is important to maintain. Key issues limiting the clinical utility of adeno-associated viral (AAV) vector -based gene therapies delivered by direct intracochlear injection are (i) suboptimal delivery of genes across all turns of the cochlea spiral (ii) suboptimal cochlea transduction efficiency in *adult* mammals and (iii) very low levels of SGN transduction. Neurotrophic Factors (NTFs) are of intense interest, and despite relatively modest transduction efficiency with intracochlear delivery (5-10%), up to 14% of the SGN population has been rescued with AAV2-NTF. These studies demonstrate the potential of AAV-based NTF gene therapy and make a compelling case for improving SGN transduction efficiency. We have shown that delivery route can impact AAV-mediated tropism, and that axonal transport can be utilized to deliver genes to brain regions distal from the injection site, the directionality of which is serotype dependent. **Hypothesis:** We hypothesized that targeted delivery of AAV vectors to the brainstem nuclei which innervate the cochlea (cochlea nucleus (CN) and superior olivary complex (SOC)) can be utilized to deliver transgenes to the SGNs in the cochlea via axonal transport. Neurosurgical approaches are considered invasive, however our group has extensive experience in safely targeting AAV-based gene therapies to various subcortical regions in multiple clinical trials utilizing intraoperative MRI guidance and believe the potential improvements in quality of life, present a strong case for development of this approach. **Results:** We show that

AAV-mediated axonal transport can be utilized to transduce SGNs which innervate both IHCs and OHCs with high efficiency across the cochlea spiral following direct intraparenchymal convection enhanced infusion into the SOC and CN of adult rats. An optimized surgical trajectory was developed to avoid damaging brainstem nuclei important for vital life functions. Coclear transduction was observed with the following major AAV serotypes expressing the reporter gene green fluorescent protein (GFP): AAV2, AAV6, AAV9, AAV-Anc80, and a novel AAV serotype developed in-house, AAV-LC.V1 which undergoes bidirectional axonal transport. Transgene delivery was most robust with the AAV-LC.V1 vector, with SGN transduction observed in all cochlear turns (apical, middle and base) at lower titers than those required for the majority of AAV vectors. Transgene expression was limited to neurons, which are not antigen presenting. Importantly, ABR testing revealed infusate delivery to the brainstem of adult rats does not negatively impact hearing. We also show that secreted transgenic GDNF can be taken up by inner HCs, which contain GDNF receptors. **Conclusions:** This study provides proof of concept that targeted AAV delivery to the brainstem can efficiently deliver transgenes to the adult mammalian cochlea via axonal transport.

1379 Development and Validation of a Novel Adeno-Associated Viral Gene Therapy for Mucopolysaccharidosis IIIB (MPSIIIB)

Francoise Piguet
TIDU GENOV, ICM, Paris, France

MPSIIIB is an autosomal recessive lysosomal storage disorder, caused by alpha-N-acetylglucosaminidase (NaGlu) enzymatic deficiency leading to accumulation of Heparan Sulfate Oligosaccharides (HSO) in tissues including the central nervous system (CNS). Patients manifest with early developmental delays followed by severe behavioral abnormalities, progressive neurodegeneration, and death before the age of 20 years. To date, there are no curative therapies for MPSIIIB. We have previously conducted a AAV-2/5 phase I/II intracerebral gene therapy trial that has shown promising results in four MPSIIIB patients with best results being obtained in the youngest patient (18 months-old). However, disease progression in tissues as important as meninges, brain capillary walls, and choroid plexus was presumably not stopped. Therefore, treatment of patients younger than 2 years and the delivery of NAGLU both within and outside the brain was concluded. Here we describe a novel AAV gene therapy using AAVPHP.eB-CAG-NaGlu vector. Following a unique intravenous and intraparenchymal administrations in MPSIIIB mice, high NaGlu activity was measured in the brain, cerebellum, and spinal cord starting 4 weeks post-treatment and persisted after 22 weeks post-treatment. This was accompanied by the normalization of GAG storage levels and improvements in lysosomal pathology and neuroinflammation. AAVPHP.eB-CAG-NaGlu treatment improved motor and cognitive functions. The vector biodistribustion and first assessment of tolerance combining intraparenchymal delivery in the white matter and intravenous delivery was performed in non-human primate. Post-surgery MRI images showed no oedema and perfect tolerance at 1 and 6 weeks post-surgery. A two-fold increase in NaGlu enzyme activity was measured in serum. NaGlu enzymatic activity in the different parts of the brain showed a very significant increase in the white matter, internal capsule, corpus callosum and in the caudate and putamen. Our data indicate that AAVPHP.eB-CAG-NaGlu is a promising treatment option for MPSIIIB patients.

1380 Rationally Engineered Novel AAV Capsids for Intraarticular Gene Delivery

Wenjun Li, R. Jude Samulski, Chengwen Li
Univeristy of North Carolina at Chapel Hill, Chapel Hill, NC

Arthritis is a group of inflammatory musculoskeletal conditions involving different joints in the body. They usually come with agonizing pain or discomfort that impact daily activities. The current systemic treatments using biological drugs come with various side effects while local treatments often require multiple visits. Due to these drawbacks, intraarticular gene therapy, particularly with adeno-associated virus (AAV) vectors, has been explored to address the most severe problems in local sites. There are three main considerations when AAV vectors are used for intra-articular gene delivery: transduction efficiency in the joint; off target transduction in other tissues, and the existence of AAV neutralizing antibodies (Nabs) in joint fluid. We first screened AAV1-9 vectors encoding firefly luciferase (AAV/luc), 5x109 vg AAV vectors were administered into the knees of C57BL/6 mice. The results from mouse imaging and in vitro luciferase assays showed that AAV 6 had the best knee joint transduction, followed by AAV1, 8, 9, 7, 2, and 5, while AAV3 and AAV4 obtained the lowest transduction. The mice administered with AAV 7, 8, and 9 vectors also displayed luciferase expression in the liver. We also compared AAV transduction under inflammatory and normal conditions using collagen induced arthritis mouse model (CIA), it showed CIA mice exhibited a higher transduction starting from 3mo since priming dose of arthritis induction, till 12mo (our ending point). It was reported that variable region I (VRI) is one of the key determinants for AAV transduction and neutralizing antibody binding, to develop a more effective AAV vector for joint targeted gene delivery, we rationally engineered a set of novel AAV capsids with substitution of VRI between AAV2, AAV6, and AAV8. The results showed the substitution of VRI from AAV6 into either AAV2 or AAV8 increased joint transduction when compared to AAV2 or AAV8 before modification: the mutant AAV2-VRI-6 (created by replacing VRI of AAV2 with that of AAV6) showed a 3-fold higher transduction efficiency than AAV2, and the mutant AAV8-VRI-6 (created by replacing VRI of AAV8 with that of AAV6) had a 2-fold higher transduction efficiency than AAV8. Interestingly, the mutant AAV6-VR1-8 with substitution of VRI from AAV8 into the AAV6 capsid had an 8 -fold lower transduction efficiency than AAV6, while the mutant AAV6-VRI-2 with swapping of VRI from AAV2 into AAV6 induced similar joint transduction to AAV6 with no significant difference. It is worth noting that mice injected with AAV6-VR1-2 displayed lower Nab titers against AAV6 and higher transduction efficiency per copy number than AAV 6. There is only a two amino acids difference between VRIs from AAV2 and AAV6. To further investigate the role of each amino acid in enhancing AAV6 joint transduction, we made two other novel AAV capsids: the mutant AAV6D, with a deletion of the 265 amino acid threonine, and the mutant AAV6M, with a mutation of the 263 amino acid from alanine to glutamine. After direct joint injection, AAV6M experienced a 100-fold decrease in transduction compared to AAV6, while AAV6D induced a 2-fold higher transduction efficiency than AAV6 and AAV6-

VR1-2. Additionally, Nab titers in mice injected with AAV6D were low, with a titer of less than 1:10 in mouse serum. Similar to AAV6, the transgene expression in mice receiving AAV6D vectors was mainly restricted to the injected joints, with less than 0.01 viral particles per cell detected in the liver. Immunohistochemistry staining with rabbit anti-luciferase antibody also demonstrated that AAV6D successfully transduced synoviocytes (29.3±4.5%) and chondrocytes (26.8±4.1%). These results from our study demonstrate that VRI from AAV6 plays an important role in joint transduction efficiency, and that novel AAV mutant AAV6D is able to enhance joint transduction after intra-articular administration, evade AAV Nabs, without crossing the local barrier and entering the blood.

1381 Increasing Feasibility and Safety of Transcutaneous Ultrasound-Mediated Gene Delivery via Intravenous Injection of Plasmids and Microbubbles

Ting-Yen Chao[1], Carol H. Miao[1,2]

[1]Seattle Children's Research Institute, Seattle, WA,[2]Department of Pediatrics, University of Washington, Seattle, WA

Ultrasound-mediated gene delivery (UMGD) is a promising non-viral method of gene therapy that utilizes therapeutic ultrasound (US) and microbubbles (MBs) to facilitate gene transfer. The current study aims to develop a noninvasive intravenous non-viral gene delivery protocol in combination with transcutaneous US in mouse models to achieve efficient transfection of plasmids in the liver. We embarked our investigation on screening for the optimal formulation of plasmid and MB mixture, the best US settings, and application procedure in a mouse model. A DNA binding study showed that the plasmid DNA can stably bind to our cationic microbubbles (RC2K; 0.011 pg DNA per MB) after 5 minutes incubation time. Thus, a secreted luciferase reporter plasmid was mixed with RC2K MBs for 5 minutes, and subsequently injected into groups of mice via retro-orbital injection with simultaneously transcutaneous application of US to the liver for 60 seconds. Following gene transfer, the transfection efficiency was periodically evaluated by luciferase expression in mouse plasma using the secreted luciferase assay. We found that gene transfection is dose dependent on the luciferase plasmids, reaching a plateau expression level with 50 μg plasmid DNA. Furthermore, a range of RC2K MB percentages (5%-12.5%) can effectively cavitate cells with 10% MBs concentration showing the best transfection efficiency. Additionally, we found that US applied within 30 seconds post-injection of the solution produced higher luciferase expression levels. Furthermore, targeting the liver via scanning on the abdomen was the most effective transducer position that produced the least amount of liver damage to the mice. The US parameters used in our experiments include: a center frequency of 1.1 MHz, a pulse repetition frequency of 14 Hz, and 14 cycles of a 1-second ON and 2-seconds OFF pulse train with a total treatment time of 60 seconds. The peak negative pressure (PNP) of the US was set at 1.5 MPa, and the pulse duration was 150 μs. In our ongoing optimization of the transcutaneous UMGD (tUMGD) technique, we are experimenting with different PNPs and pulse duration values. In most US conditions, we have observed expression levels of up to 5 - 8 x10^4 RLU/mg. Additionally, we are testing the effect of double treatments, and have observed expression levels of over 10^5 RLU/mg protein. In conclusion, tUMGD is a minimally invasive, non-viral, and effective method of gene therapy. By injecting the plasmid DNA/MBs mixture intravenously and applying US to the target organ transcutaneously, this optimized tUMGD technique can be easily translated to treat genetic disorders in clinics.

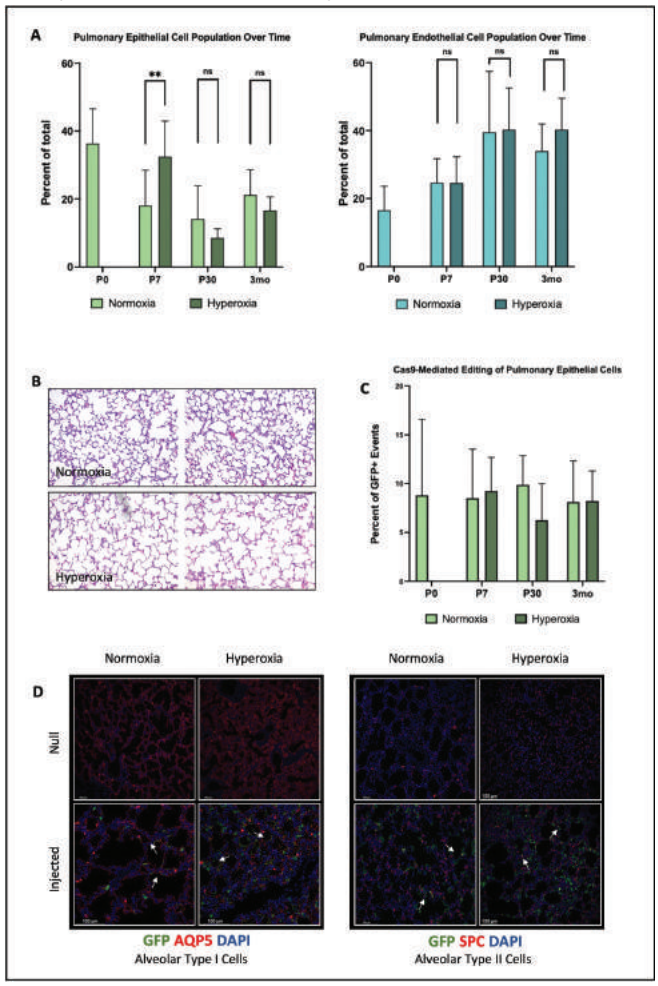
1382 *In Utero* Pulmonary Gene Editing Persists after Postnatal Lung Injury

Valerie L. Luks[1,2], Apeksha Dave[2], Cara L. Berkowitz[2], John S. Riley[2], Marco Carpenter[2], Philip W. Zoltick[3], William Peranteau[2]

[1]Department of Surgery, University of Pennsylvania, Philadelphia, PA,[2]Division of Pediatric General, Thoracic and Fetal Surgery, Children's Hospital of Philadelphia, Philadelphia, PA,[3]Children's Hospital of Philadelphia, Philadelphia, PA

RATIONALE:Monogenic lung diseases are prime targets for *in utero* gene editing to treat and ultimately cure disease prior to the onset of irreversible pathology. Despite novel treatments, patients with congenital pulmonary disorders remain at increased risk of lung injury at birth, whether due to trauma from mechanical ventilation and high oxygen requirements, or increased susceptibility to pulmonary infections. For *in utero* gene therapies to be clinically applicable, it is important to determine whether cells that undergo genetic manipulation retain long-term genotypic stability when subjected to cellular stress. We therefore sought to assess the fate of prenatally edited pulmonary cells in a hyperoxia-induced postnatal lung injury model to determine the persistence of gene editing after postnatal insult. METHODS:The *ROSA^{mTmG}* reporter mouse model constitutively expresses a red fluorescent protein gene that can be excised by Cas9-mediated cleavage, thereby activating expression of green fluorescent protein in all cells that undergo gene editing. Intraamniotic injection of an adenovirus containing SpCas9 and guide-RNA targeting the cleavage sites was performed at gestational day 16. At birth, neonatal mice were placed into either normoxic or hyperoxic (85% oxygen) environments. Hyperoxic treatments lasted seven days after which time all mice were placed in normoxic conditions until the predetermined timepoints. Analysis was carried out at 0, 7, 30 and 90 days. Flow cytometry was performed to quantify pulmonary cell types (epithelial cells (EPCAM+) and endothelial cells (CD31+)) as well as gene editing efficiency based on GFP-positivity. Immunofluorescent microscopy was used to identify whether the expression of alveolar type I (AQP5+) or alveolar type II (SPC+) cells differed after injury and whether gene editing persisted in both cell types. RESULTS: At birth, there were relatively more epithelial cells within the lungs compared to endothelial cells. As the saccular and alveolar stages of lung development progress, there was a relative increase in pulmonary endothelial cells associated with capillary network expansion with a mirrored decrease in epithelial cells as the alveoli expand and develop (Figure 1A). While hyperoxia resulted in alveolar simplification (Figure 1B), there was no difference in relative cellular composition of mouse lungs after injury. Importantly, pulmonary epithelial cell editing remained consistent over time independent of normoxia and hyperoxia exposure (9.8% vs 9.5% at 3 months, respectively) (Figure 1C). Immunofluorescent staining for alveolar type I (AQP5+) and II (SPC+) cells demonstrated GFP positivity in both the normoxia and hyperoxia groups at 90 days, suggesting successful and persistent gene editing of the progenitor type II cells despite injury (Figure 1D, arrows

indicate double positive cells). CONCLUSION:Despite lung injury, prenatal gene editing of pulmonary epithelial cells persists, suggesting neither selection disadvantage nor other detrimental side effects of SpCas9-mediated gene editing exists in the lung. Further, successful editing and subsequent stability of the progenitor cells within the lungs is encouraging as we move towards the development of clinical gene editing approaches to address congenital disease.



1383 Optimization of AAV Transfer Vector for Microglia Specific Transgene Expression

Ruotong Zhao

Temple University, Philadelphia, PA

Microglia, the primary innate immune cells of the central nervous system (CNS), play critical roles in brain development and homeostasis as well as the pathogenesis of many neurological conditions. Transgene delivery to microglia is a promising therapy for CNS injury and disease. Extensive efforts using various types of AAV library screening have identified an increasing number of blood brain barrier (BBB)-crossing serotypes (AAV-B) that can efficiently transduce neurons and astrocytes. Unfortunately, almost all of them failed or had a limited capacity to transduce microglia likely due to the lack of a microglia-specific AAV transfer vector. To help identify ideal AAV serotypes that can efficiently cross BBB and specifically transduce microglia (AAV-BM), we developed a new AAV transfer vector with microglia-specific transgene expression (pDsAAV-HexB-UTR-iCre-WPRE3-miR9T-BGH, 2.418 kb including 2 ITRs). The self-complementary double-stranded AAV transfer vector (DsAAV with packaging capacity around 2.4 kb) was selected to increase the transduction and transgene expression. The minimal/essential promoter of microglia-specific gene HexB (135 bp) was used due to its small size, high specificity and pathological upregulation. The SARS-CoV-2 5'-UTR and the shortest WPRE3 were included to boost the mRNA expression of the transgene. The 4x repeated miRNA-9 target site (miR9T) was added downstream of WPRE3 to illuminate microglia expression (due to miR9 absence) but conceal transgene expression in non-microglia cells that endogenously express miR9, such as neurons, astrocytes, neural stem cells, oligodendrocytes, etc. Finally, the improved Cre (iCre)-mediated LoxP-STOP-LoxP (LSL)-tdTomato (tdT) reporter transgenic animal model (Ai14) was chosen to increase the sensitivity of detecting AAV transduction efficiency because a single copy of iCre delivered by AAV could remove STOP terminator for strong tdT expression. The functions of HexB promoter and miR9T were validated using pDsAAV-HexB-GFP-miR9T vector packaged with AAV2 and AAV-PhP.eB in human microglia and mouse neural stem cells. The packaging efficiency of pDsAAV-HexB-UTR-iCre-WPRE3-miR9T-BGH was assessed by standard 3-plasmid packaging in HEK293T cells with the titer at 1.84e13 GC/ml, comparable to the standard pDsAAV-Cb-GFP. In cultured neural stem cells from Ai14 mice, AAV-iCre-miR9T showed very few positive cells even at 1e6 MOI, while AAV-iCre without miR9T exhibited high transduction efficiency in a dose-dependent manner. In cultured mouse microglia, AAV-iCre-miR9T induced dose-dependent transduction as determined by tdT positivity. Mouse brain stereotactic injection of purified AAV-iCre-miR9T viruses (3.68e10 GC/mouse, 2 µl/site) induced local expression of tdT specifically in microglia. In conclusion, a novel and optimal AAV transfer vector is maximized for its high specificity and sensitivity in transducing microglia both in vitro and in vivo. This vector is useful in screening novel AAV-BM serotypes with BBB-penetration and microglia transduction.

1384 Subretinal Delivery of an AAV Gene Therapy Product Significantly Inhibited the Neovascularization in a Laser-Induced CNV Rhesus Model

Qiang Zheng[1], Qingwei Li[1], Shuang Luo[1], Hao Jiang[1], Yingfei Qin[1], Fan Yang[1], Aibing Liu[1], Avner Ingerman[2], Anna Oughton[2], Shawn Patrick Shearn[2], Qing Xie[1], Xiao Ke*[1,3]

[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, China,[2]Vanotech Ltd, Rockaway, NJ,[3]Chengdu Kanghong Pharmaceuticals Group Co Ltd, Chengdu, China

Currently available treatments for neovascular Age-related macular degeneration (wAMD) include Conbercept,Aflibercept, Ranibizumab, Faricimab and Bevacizumab which are antibodies targeting the VEGF axis. These medications are administered regularly and frequently by intravitreal injection, which is an invasive manipulation causing inconvenience to the patients. The purpose of this study is to develop a therapeutic strategy that have a long-lasting effect with reduced administration frequency, potentially even a single administration. We developed a gene therapy medication (KH631) that encodes

anti-VEGF (Conbercept) transgene inside a rAAV8 vector (AAV8-Conbercept). The therapeutic potency of the KH631 was evaluated in a related pharmacodynamic NHP model. Rhesus monkeys were randomly divided into three groups, each animal was administered with KH631 at target dose levels including 3E9, 1E9 and 3E8 vg/eye via subretinal injection respectively. 3 animals were included in each dose group. 28-days post injection animals were subject to laser injuries to their Bruch's membrane, which induce growth of new blood vessels in the subretinal space, mimicking the main characteristics of human wAMD patients. Two animals were used as positive controls which were administrated with 0.5 mg/eye of Conbercept immediately after laser injury. The percentage of grade-4 lesions and the fluorescein leakage (FL) areas of the retina, reflect the neovascular dysfunction severity, and were determined by fluorescein fundus angiography (FFA) at 2- and 4-weeks post damage. At week-2 timepoint post damage, the choroidal neovascularization (CNV) grade-4 lesion inhibition rate was 100%, 91.67% and 73.0% at dosage of 3E9, 1E9 and 3E8 vg/eye groups respectively; in the Conbercept group the inhibition rate was 100%. In the untreated group the number of grade-4 lesion decreased from 36 loci to 28 loci (22.2% reduction). At week-4 timepoint post damage, inhibition was 100%, 94.44% and 90% respectively for the treatment group, and 95.8% for the Conbercept group; the untreated group had 24 loci of grade-4 lesion remaining in total of 38 loci (33.3% reduction). Overall, the FL areas greatly decreased when compared with untreated controls (Figure 1). In conclusion, the data illustrated that a single subretinal injection of KH631 efficiently protected the NHP's retina against CNV related pathological damages. The new gene therapy strategy may potentially have a clinical effect.

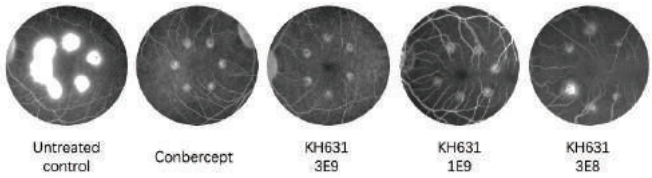


Figure 1. Representative images of fluorescein leakage (FL) test in animals' eyes. KH631 vectors were injected subretinally into rhesus monkeys' both eyes with dosage of 3E8, 1E9 and 3E9 vg/eye respectively; saline was used as the untreated control. Laser modeling was conducted 28 days post injection for all the animals in both eyes; Two animals were laser injured and injected immediately with 0.5 mg/eye of Conbercept as positive controls. FL test was performed at week-4 post modeling, images show the representative images of fluorescein fundus angiography (FFA).

1385 Efficient Gene Correction Strategy for *Recombination Activating Gene 1 (RAG1)* Deficiencies in Human Hematopoietic Stem Cells

Chiara Brandas[1,2], Maria Carmina Castiello[1,3], Samuele Ferrari[1], Simona Porcellini[1], Nicolò Sacchetti[1], Daniele Canarutto[1,4], Valentina Vavassori[1], Angelica Varesi[1], Gabriele Pelosi[1,4], Elena Draghici[1], Martina Di Verniere[1], Ivan Merelli[1,5], Lucia Sergi Sergi[1], Enrica Calzoni[1], Marita Bosticardo[6], Gay Crooks[7], Luigi Notarangelo[6], Pietro Genovese[8], Luigi M. Naldini[1,4], Anna Villa[1,3]

[1]San Raffaele-Telethon Institute for Gene Therapy (SR-Tiget), Milan, Italy,[2]Translational and Molecular Medicine (DIMET), University of Milano-Bicocca, Milan, Italy,[3]Milan Unit, Istituto di Ricerca Genetica e Biomedica (IRGB), Consiglio Nazionale delle Ricerche (CNR), Milan, Italy,[4]Vita-Salute San Raffaele University, Milan, Italy,[5]National Research Council, Institute for Biomedical Technologies, Milan, Italy,[6]Laboratory of Clinical Immunology and Microbiology, NIAID, NIH, Bethesda, MD,[7]Department of Pathology and Laboratory Medicine, David Geffen School of Medicine, Univ. of California, Los Angeles, CA,[8]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, MA

Genome editing based on CRISPR-Cas9 and homology-directed repair (HDR) is a powerful tool for precise *in situ* correction and restoration of the physiological gene regulation, although it is still challenging on hematopoietic stem/progenitor cells (HSPCs). We have developed genome editing strategies to restore the expression and function of the *Recombination Activating Gene 1* (*RAG1*), a key player of the V(D)J recombination process that is tightly regulated during lymphoid differentiation and leads to a spectrum of severe immunological disorders when mutated. A panel of CRISPR/Cas9 nucleases and corrective donors carrying a codon-optimized *RAG1* (co*RAG1*) were screened exploiting a RAG1-deficient cell line (NALM6-*RAG1*.KO) and human mobilized peripheral blood CD34+ HSPCs derived from healthy donors (HD) and RAG1 patients (Pt) carrying biallelic hypomorphic *RAG1* mutations. The first developed genome editing strategy targeted the *RAG1* intron 1 and delivered a co*RAG1* cassette with an upstream splice acceptor sequence to allow transgene expression under the control of the endogenous *RAG1* promoter. Low and variable levels of RAG1 function were achieved in edited NALM6-*RAG1*.KO cells associated with no substantial gene expression modulation in G0/G1 cell cycle phases. Despite the good levels of HDR in edited HD and Pt-derived HSPCs, limited improvement in the lymphoid differentiation after editing of Pt-HSPCs was observed in a 3D *in vitro* model and i*n vivo* in transplanted NOD scid gamma (NSG) mice. Based on these results, we subsequently targeted the *RAG1* exon 2, which is the only coding exon, and developed two different corrective DNA templates to improve the therapeutic potential of our gene correction strategy. Both exon 2 strategies allowed the correction of RAG1 recombination activity and physiological regulation of gene expression in edited NALM6-*RAG1*.KO cells. Importantly, edited Pt-derived HSPCs overcame the T-cell block and differentiated in TCRα/β+CD3+ cells in artificial thymic organoids. *In vivo* experiments in NSG mice transplanted with HD and Pt-derived HSPCs showed engraftment and multilineage differentiation of edited

cells and, importantly, confirmed the efficacy of both exon strategies in overcoming the block of lymphoid differentiation. Moreover, the efficiency of gene correction reached by the exonic editing strategies exceeded the minimal proportion of functional HSPCs that we found to be required to rescue RAG1 immunodeficiency in Rag1$^{-/-}$mice. In conclusion, our findings indicate the feasibility and efficacy of genome editing for the correction of the human *RAG1* locus, strongly supporting its clinical translation for the treatment of RAG1 deficiency, including hypomorphic forms of the disease.

1386 Lipid Nanoparticle Formulations for the Systemic Delivery of CpG-STAT3 siRNA to Myeloid Immune Cell for Cancer Immunotherapy

Elaine Kang[1], Dongfang Wang[1], Wilson Tang[1], Alan Horsager[2], Marcin Kortylewski[1]

[1]Immuno Oncology, City of Hope, Duarte, CA,[2]Duet Therapeutics, Pasadena, CA

We previously demonstrated that eliminating tolerogenic STAT3 signaling from the tumor microenvironment together with Toll-like receptor 9 (TLR9) stimulation results in potent antitumor immune responses. Our proof-of-concept strategy, naked CpG-STAT3siRNA oligonucleotide, proved effective in preclinical studies in mice against human and mouse tumor models, such as leukemia, b cell lymphoma, melanoma, glioma, bladder, and colon cancers. To optimize this strategy for the systemic administration, we utilized MC3-based lipid nanoparticle (LNP) formulations since such delivery systems emerged in recent decade as an attractive tool for gene therapy. After testing LNP compositions varying in N:P ratios and PEG content, we focused on the LNPs with maximal TLR9-mediated immune stimulation as well as target gene silencing. CpG-STAT3siRNA encapsulated in the LNP2 formulation (~100nm in diameter) showed robust type I IFN production (5-10ng/ml of IFNα) in human peripheral blood mononuclear cells (PBMCs) as measured by ELISA. It also resulted in over 50% *STAT3* knockdown in human OCI-Ly3 B cell lymphoma cells as well as in U251 glioma cells at the low oligonucleotide concentration of 100nM in vitro. Importantly, LNP2(CpG-STAT3siRNA) showed ~10× improved potency compared to the naked oligonucleotide against two human lymphoma xenotransplants. Next, we optimized LNP2 formulation using various of anionic helper lipids to maximize targeting of human immune cells. Two of the new LNP2 variants indicated preferential uptake by either human monocytes and dendritic cells (LNP2^{PG}) or by human B cells (LNP2^{CHEMS}). The biodistribution of both LNP2^{PG} and LNP2^{CHEMS} was further verified in biodistribution studies in immunocompetent mice bearing disseminated, syngeneic acute myeloid leukemia (AML). Within 3 h after intravenous injections (1mg/kg), we found significant differences in the cell specific distribution of tested LNPs. As expected, LNP^{PG}(CpG-STAT3siRNA) showed selectivity targeting myeloid cells, including DC subsets, in lymphoid organs such as spleen, lymph node and bone marrow compared to all other formulations. Unlike in human immune cell testing, LNP2^{CHEMS} failed to demonstrate B cell specific targeting in mice. While studies are ongoing, our results so far suggest potential species-specific differences between LNP targeting properties and underscore the need for testing in the context of human immune system in vitro or in humanized mouse models. We believe that the new LNP2^{PG} formulation will provide vehicle for targeting human hematologic malignancies and solid tumors which rely on the tolerogenic myeloid cells for immune evasion.

1387 LT-CRISPR, a Novel Gene-Editing Tool for Precise Editing of the Human Genome

Sibtain Haider, Toni Cathomen, Claudio Mussolino

Medical Center - University of Freiburg, Freiburg, Germany

Genome editing has emerged as a promising strategy to treat various disorders affecting the hematopoietic system. The importance of precise genome editing lies in the fact that it reduces the likelihood of off-target effects, which can cause unintended changes to the genome and lead to harmful side effects. However, therapeutic applications of DNA nucleases suffers from the intrinsically low frequency of homology-directed repair (HDR) compared to Non-homologous end joining (NHEJ) at target site. Presence or absence of different effectors and homologous template at targeted DNA break directs the DNA repair pathway toward HDR or NHEJ. We have demonstrated that by complementing the necessary effectors with Cas9 we can inhibit NHEJ and increase HDR events at targeted site. Using our previously established HDR-CRISPR, we were able to achieve 3-fold increase in precise genome editing as compared to the unmodified Cas9. Here we developed a novel linked-template CRISPR system (LT-CRISPR) to enrich the repair template at DNA double strand break (DSB). We demonstrate that LT-CRISPR is capable of efficiently capturing a single stranded DNA repair template and deliver it directly to the site of the DSB where it promotes DNA repair with 4 fold higher precision for small amino acid change in comparison to unmodified Cas9. Further screening of effectors involved in DNA repair has led to the identification of new fusion partners for the Cas9 that favour the HDR-mediated resolution of a DSB. Ongoing experiments explore the efficacy of LT-CRISPR in fusion with newly identified effectors to correct Fanconi Anemia (FA) specific mutations in-patient-derived hematopoietic stem cells. We believe LT-CRISPR system offers the opportunity to pursue precise genome editing when DNA repair mechanisms are impaired as a consequence of the underlying genetic defect.

1388 AAV Gene Therapy for CSA-Linked Cockayne Syndrome

Aine Scholand, Miguel Sena-Esteves, Ana Rita Batista

Neurology / Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA

Cockayne syndrome (CS) is an autosomal recessive disease caused by mutations in either the CSA (ERCC8) or CSB (ERCC6) gene, leading to defects in transcription-coupled nucleotide excision repair and RNA Pol II mediated transcription. Patients with CS present hypersensitivity to UV light, severe growth failure, dwarfism, short life span and a progressive degeneration of the central nervous system, as well as eye abnormalities (congenital cataracts and retinal degeneration) and hearing loss. The average life expectancy for CS patients is 12 years. Currently there are no therapies for these patients, with the disease being managed symptomatically. CSA is ubiquitously expressed, but its function is not fully understood. It is known to be part of a larger group of proteins with ubiquitin ligase activity thought to regulate both

RNA PolII and CSB. Previous studies have shown that re-expression of normal CSA protein in CSA-associated CS patient cells restores their DNA repair capacity.We designed a panel of self-complementary AAV vectors encoding human CSA under promoters of various strengths. Initial experiments in CRISPR/Cas9 engineered CSA-KO HEK293T cells showed a gradient of protein expression levels assessed by western blot. Accordingly transient transfection of CSA knock-out (KO) HEK293T cells with all AAV constructs restored their survival in a killing assay after treatment with the chemotherapeutic drug Illudin S.Unlike CS patients, CSA-KO mice do not display an overt phenotype and have a normal life span. A severe phenotype is only observed in double CSA/XPA KO mice with very low body weight (< 5 g at weaning) and reach a humane endpoint by 23 days of age. We are testing the therapeutic efficacy of scAAV9-CSA vectors by neonatal ICV injection in CSA/XPA KO mice. Currently several CSA/XPA KO mice treated with the top dose of scAAV9-CSA are ~130 days of age, an increase in lifespan >6-fold (Fig.1), with body weight comparable to that of age matched littermates and no documented adverse events. Importantly the increase in survival is dose dependent. Broad distribution of transduced cells in the brain was documented by immunohistochemical staining for human CSA, and confirmed by western blot analysis of protein expression. Currently we are enrolling more animals in the experiment and testing intermediate doses to identify a minimum effective dose.The success of these AAV proof-of-concept experiments support transition to a clinical trial in CS patients.

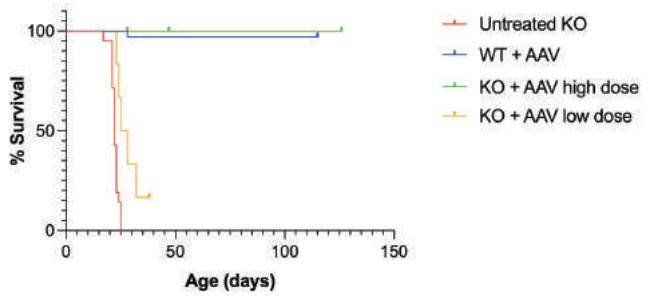

Figure 1. Kaplan-Meier survival plot of CSA/XPA KO mice.

1389 Engineering of the AAVrh.10 Capsid for Cardiac Gene Transfer

Slawomir Andrzejewski, Kalpita R. Karan, Katie M. Stiles, Neil R. Hackett, Ronald G. Crystal

Department of Genetic Medicine, Weill Cornell Medicine, New York, NY

Intravenous administration of AAV serotype rh.10 mediates high level of transduction of the myocardium and is being used to treat hereditary cardiac disorders. However, as with other AAV serotypes, intravenous AAVrh.10 administration also results in high level distribution to the liver which could be a safety concern. The objective of this study was to modify the AAVrh.10 capsid to de-target the liver while retaining effective transduction of the myocardium. Modifications to the AAVrh.10 capsid employed rational engineering. Two variable regions at amino acids 452 and 589 of the capsid VP1 gene were chosen to insert oligopeptides of 5-12 amino acids based on modifications in other AAV serotypes combined with novel molecular modeling. The cardiac and hepatocyte transduction efficiencies of 30 peptide-modified AAVrh.10 capsids expressing the luciferase gene driven by the ubiquitous CAG promoter were first tested *in vitro* in the human cardiomyocyte AC16 and T0539 cell lines and human hepatocyte Huh-7 cell line. Of the initial 30 engineered capsids, 9 had the desired characteristic of de-targeting liver cells while retaining efficient transduction of cardiac cells. Insertion of sequences containing the RGD integrin binding motif in the middle of the inserted peptide in loop VIII helped mediate cardiac-specific transduction. Ten different RGD-containing vectors gave an average expression level 4.0±1.2-fold higher in T0539 cells and 2.8±0.9 higher in AC16 cells compared to all vectors without the RGD motif ($p<0.05$). The optimal *in vitro* engineered capsids were each tested in n=5 C57Bl/6 mice with an intravenous dose $2.5x10^{10}$ genome copies. Two weeks following administration, vector DNA from harvested organs was quantitated. Compared to the wildtype AAVrh.10 capsid, variant M2 (NNPTPSR insertion at position 588) showed a 1.4-fold higher level in heart combined with a 185-fold lower distribution to liver, resulting in a 259-fold higher cardiac to liver specificity. Variant 36.10 (IDGAATK substitution at 452-458 and insertion of ENHTKND at 588) had a 1.3-fold higher level in heart with a 117-fold decrease in liver distribution, resulting in 152-fold increase in heart to liver specificity. In summary, modification of the capsid of AAVrh.10 resulted in effective heart distribution while de-targeting liver. Pending confirmation in larger animals, these vectors may provide an improved organ specificity for cardiac gene therapy.

1390 Dissecting the Effect of Truncated Inverted Terminal Repeats on Productivity, Packaging and Quality of AAV Vectors

Yinxing Chen, Shiliang Hu, Nannan Jia, June Deng, Noel Walsh, William Lee, Joy Wang, Megan Ericson, Lauren M. Drouin, Gregory Preston, Jing Liao, Matthias Hebben

Alexion, AstraZeneca Rare Disease, Lexington, MA

The inherent instability of inverted terminal repeats (ITRs) is one of the major challenges when working with Adeno-associated virus (AAV). ITRs are involved in replication, encapsidation, and integration of AAV genomes. The high GC content and palindromic structure of ITRs facilitates truncations and mutations during plasmid amplification in bacterial cells. It has been shown that even with truncated ITRs, the rAAV genomes can still be replicated efficiently. Deletion of both B-B' and C-C' regions was reported to reduce the rAAV productivity but interestingly increased transgene expression. However, it is more common to observe deletion of either B-B' or C-C', which is known to be less impactful for vector production, as these minor deletions can self-repair during AAV vector genome replication The self-repair is believed to happen when the second ITR is intact, so it can be used as the DNA template during replication. Consistently, our team also observed that B -B' or C-C' region deletion of one of the ITRs showed no significant impact on productivity, packaging efficiency or in vivo potency compared to wild type ITRs. We also observed, using different sequencing methods, that a B-B' deletion in one of the ITRs could be rescued during AAV production. Since self-repairing of the truncated ITR may underestimate the deletion impact, we created a set of vectors with various deletions in the ITR region, at one end and at both ends of the vector genome. We assessed the impact of these deletions in the key regions of the ITR, including the two palindromic loops (B-B' and

C-C'), A region and D region. After producing the vectors using a three-plasmid system transfection of HEK293 cells, the crude harvest lysates were collected and characterized for productivity, full-to-empty capsid ratio, potency, and ITR integrity by sequencing. The result of this work helps to further the understanding of the impact of truncated ITRs on rAAV productivity and qualities during the manufacturing process.

1391 First-in-World Clinical Trial of Genetically Engineered B Cells: Application to the Treatment of Mucopolysaccharidosis Type I

R. Scott McIvor[1,2], Christiane Hampe[1], Glen Grandea[1], Erik R. Olson[1], Kole D. Meeker[1], Cassidy Papia[1], Joelle Solan[1], Monika Swietlicka[1], Robert Hayes[1], Sean Ainsworth[1], Paul J. Orchard[3], Jacob Wesley[1], Robert Sikorski[1]

[1]Immusoft Corporation, Seattle, WA,[2]Dept. of Genetics, Cell Biology and Development, University of Minnesota, Minneapolis, MN,[3]University of Minnesota, Blood and Marrow Transplant & Cellular Therapy, Minneapolis, MN

Due to their capacity for high-level protein production and their natural ability to engraft in bone marrow without need for toxic preconditioning, B cells have the potential to serve as a highly efficacious cellular therapy. Immusoft Corp. has established effective conditions for expansion and genetic engineering of human peripheral blood B cells using the *Sleeping Beauty* (SB) transposon system. Here we present the first genetically engineered B cell product (ISP-001) to achieve US FDA clearance for clinical testing, in this case for the treatment of mucopolysaccharidosis type I (MPS I). MPS I is a rare ($1/10^5$) lysosomal disease caused by absence of α-L-iduronidase (IDUA), leading to systemic accumulation of glycosaminoglycans, organomegaly, skeletal dysplasias, cardiopulmonary obstruction and neurologic impairment. Current treatments by enzyme replacement or by allogeneic hematopoietic stem cell transplant address some but not all of these manifestations. ISP-001 is an autologous B cell product engineered to express human alpha-L-iduronidase (IDUA) for the treatment of MPS I. Manufacturing of ISP-001 starts by collection of the subject's peripheral blood leukocytes by apheresis. The CD19+ population is isolated by immunomagnetic fractionation and expanded in culture for a total of 7 days under defined growth conditions. On day 2 the cells are collected and co-electroporated with an SB transposon construct containing an EEK-regulated human IDUA coding sequence, along with messenger RNA encoding SB100x *Sleeping Beauty* transposase. SB100x transposase expressed from the co-electroporated mRNA then mediates transposition of the SB-EEK-IDUA transposon from the co-electroporated plasmid into the genomes of the expanding B cell population. ISP-001 product release is characterized by flow cytometry, IDUA enzyme level and frequency of IDUA expressing cells, vector copy number and routine safety assessments. Preclinical testing of ISP-001 by xenotransfer into immunodeficient NSG-MPS I mice has demonstrated persistence of IDUA expressing cells and reduced tissue GAG storage for up to six months (the length of the study). The initial clinical trial will be carried out in adults with mild non-neuronopathic disease, testing primarily for safety, with secondary endpoints of assessing biological activity (IDUA, GAG) and initial effects on peripheral manifestations that persist in spite of enzyme replacement. Outcomes from this clinical trial will address the feasibility of this approach for the treatment of MPS I.

1392 A Humanized Mouse Model as a New *In Vivo* Platform to Study and Prevent Pre-Existing Anti-AAV T Cell Responses

Gwladys Gernoux[1], Mickael Guilbaud[1], Marie Devaux[1], Nicolas Jaulin[1], Virginie Pichard[1], Allan Avenel[1], Anthony Mellet[1], Johanne Le Duff[1], Rebecca Xicluna[1], Apolline Salama[2], Carole Guillonneau[2], Ignacio Anegon[2], Oumeya Adjali[1]

[1]Nantes University, CHU de Nantes, INSERM, TaRGeT - Translational Research in Gene Therapy, UMR 1089, Nantes, France,[2]Nantes University, CHU de Nantes, INSERM, CR2TI – Center for Research in Transplantation and Translational Immunology, UMR 1064, Nantes, France

Biotherapies using recombinant adeno-associated viral vectors (rAAV) showed a tremendous success for the treatment of genetic disorders during the last decade. However, rAAV immunotoxicity has been recently reported in patients injected systemically with high doses of viral vectors, leading in some cases to clinical trial holds. Limits imposed by the host immune system emerged when rAAV-based gene transfer protocols were translated from animal models to humans. Indeed, activation of the innate immune system or activation/re-activation of AAV capsid-specific T cells were not reported in preclinical studies despite the fact that, as humans, some large animal models are natural hosts of wild-type AAVs. The absence of relevant preclinical models limits the prediction of success or failure of gene transfer protocols and prevent the development of less immunogenic rAAV vectors or relevant and specific immune suppressive drugs. Development of relevant animal models that mimic immune responses to rAAV vectors observed in patients is crucial for rAAV immunogenicity evaluation and immunomodulation. We developed a humanized rodent model mimicking the cellular immune response described in patients. This model consists in engrafting NSG-HLA-A2+/HHD mice with human PBMCs collected from HLA-A2+ healthy donors with a preexisting anti-AAV8 cellular response and then analyzing the immune response to the capsid after IV injection of a rAAV8 vector. Mice were divided in 3 groups: mice injected with either the vector alone (n=6) or anti-AAV8 IFNγ-secreting cells only (n=3) and, mice injected with both the vector and anti-AAV8 IFNγ secreting cells (n=14, 4 different donors). Our results show an important weight loss only in mice injected with the AAV8 vector and anti-AAV8 IFNγ-secreting human cells, as well as a better engraftment of human CD45+ cells (hCD45+) in the whole blood and the spleen of this same group. These mice also showed an inflammation in the liver and liver infiltrating-cells that are mainly CD8+ T cells in opposition to control groups. A more extensive characterization of these cells is currently ongoing. Since this model appears also relevant to test immunosuppressive strategies, we are currently testing an immunomodulatory strategy using an anti-CD45RC antibody specifically targeting human memory T cell subtypes. In conclusion, this model appears promising to measure the impact of pre-existing anti-AAV T cells on gene transfer efficacy depending on donor's anti-AAV T cell phenotype. It seems also an *in vivo* powerful platform to test immunosuppressive strategies. The final outcome being

to prevent any adverse events related to a defined gene transfer product and define the patient's eligibility to gene therapy clinical trials based on their immune profile.

1393 An Evolved AAV Variant with Enhanced Brain and Spinal Cord Tropism and Translation across Primate Species

Jing Lin[1], Charlotte Chung[1], Jeff Thompson[1], Kyle Grant[1], Timothy Fiore[1], Damien Maura[1], Johnny Yao[1], Ambreen Sayed-Zahid[1], Amy Johnson[1], Wei Wang[2], Shaoyong Li[3], Nilesh Pande[1], Anupriya Kulkarni[1], Matthew Child[1], Rupinderjit Kaur[1], Zachary Thorpe[1], Xiaoqin Ren[1], Hongxing Wang[4], Mathieu E. Nonnenmacher[1]

[1]Voyager Therapeutics, Cambridge, MA,[2]Tome Bioscience, Cambridge,, MA,[3]Exegenesis Bio, Lower Gwynedd, PA,[4]Affinia Therapeutics, Inc., Waltham, MA

Intravenous delivery of evolved Adeno-Associated Virus (AAV) vectors for gene therapy of the central nervous system (CNS) represents a promising strategy for multiple neurological diseases. The improvements include combining broad transduction of brain and spinal cord tissue together with decreased toxicity risk in comparison with more invasive local administration. Our previously reported TRACER™ capsid discovery platform enables directed evolution and selection of AAVs with improved delivery to various tissues, including CNS, in non-human primates (NHPs). We applied the TRACER™ RNA-driven platform to several peptide display libraries generated by random amino acid substitutions of surface-exposed regions of AAV9. After three rounds of intravenous administration and neuron-specific library RNA selection in cynomolgus macaque, we identified a large collection of capsid variants with improved CNS tropism. In order to evaluate cross-species translatability of these variants, a pool containing the top 145 capsids was tested for CNS tropism in marmosets (*Callithrix jacchus*), African green monkeys (*Chlorocebus sabaeus*) and mouse. Although most variants did not show enhanced brain tropism in those alternative species, the top variant identified in macaques, VCAP-103, recapitulated enhanced CNS transduction in marmosets and AGM, but not in C57Bl/6 or BALB/c mouse. VCAP-103 was further validated as an individual vector in adult cynomolgus macaque using two different therapeutic transgenes, and showed a robust improvement over AAV9, with at least 20-fold higher viral genome biodistribution and transgene RNA expression across the brain and the spinal cord. Immunohistochemical staining demonstrated that this novel capsid allows widespread neuronal transduction in multiple brain regions, including the cortex, putamen, thalamus, and cerebellum, while displaying relatively low transgene expression in liver or dorsal root ganglions (DRGs), despite using a ubiquitous promoter. In summary, this work highlights the possibility of using genetically distant primate species to evaluate the translation potential of evolved AAV capsids, and identifies VCAP-103 as a potential candidate for CNS-targeting applications.

1394 Development of Patient-Derived 3D Tumor Organoids Combined with Immune Cells, as Preclinical Testing Platform for Personalized Cancer Immunotherapy

Gabriella Antignani[1], Sara Feola[1], Valentina Ferrari[2], Daniele Ciampi[2], Jacopo Chiaro[1], Michaela Feodoroff[1], Manlio Fusciello[1], Salvatore Russo[1], Firas Hamdan Hissaoui[1], Riikka Molsa[1], Markus Haapala[1], Mikaela Grönholm[1], Rui Mamede Branca[3], Maria Rescigno[2], Tiina Sikanen[1], Janne Lehtiö[3], Vincenzo Cerullo[1]

[1]University of Helsinki, Helsinki, Finland,[2]Humanitas Research Hospital, Milan, Italy,[3]Karolinska Institutet, Stockholm, Sweden

Currently available models to validate preclinical efficiency of Immunotherapies lack in mirroring or poorly recapitulate the original patient's tumor. Active immunotherapy, which is dependent on HLA-TCR interaction, cannot be tested in any other system than fully human based *in vitro* systems or humanized mice (complex, expensive, and time-consuming). Plus, only a fraction of patients will gain benefit from immunotherapy treatments and finding responsive patients in advance would be crucial. Therefore, we need to develop more sophisticated systems to address immunotherapies correct mode of actions in humans. Organoids are 3D multicellular structures that retain morphology and function of human tissues and organs. Patient-Derived Tumor Organoids (PDTOs) can be established from primary patient material, cultured long term, and cryopreserved. Successful in recalling the tumor heterogeneity and complexity *in vitro*, PDTOs can provide a robust *ex vivo* system for modelling human cancer, holding great potential as pre-clinical human platform for testing personalized therapies. Our work is focused on combining patient-derived immune cells and PDTOs to develop complex immuno-organoids that retain both patient's tumor unique features and immune system-mediated response. This allows to test tumor cell killing by the patient's own immune system after a personalized immunotherapy treatment. Moreover, after in-depth patient´s tumor characterization, we design a personalized immunotherapy approach to specifically target the patient´s tumor.Oncolytic vaccines have a dual mechanism: direct oncolysis of cancer cells and release of tumor antigens, causing cytotoxic T cell activation against cancer cells. To develop patient-specific oncolytic vaccine-based immunotherapies, our strategy is coating oncolytic vaccines with patient-specific tumor peptides (PeptiCRAd technology). We established PDTOs from Renal Cell Carcinoma and Bladder Cancer, which we characterized by DNA sequencing, immunofluorescence, drug screens. HLA ligandome analysis of the PDTOs allowed the identification of 52 patient-specific tumor peptides. We validated the immunogenicity of these peptides by stimulating healthy donor Peripheral Blood Mononuclear Cells (PBMCs) and analyzing IFN-gamma secretion or CD107a degranulation. We will also use patient-derived PBMCs to unravel the best candidate peptides able to recall a T cell antitumor response. Finally, we will investigate how an oncolytic vaccine decorated with patient-specific tumor peptides (personalized PeptiCRAd) is able to trigger tumor-specific adaptive immune response, measuring specific T cell killing of PDTOs with impedance-based Xcelligence system, LDH release and live cell microscopy. Establishing such a pre-clinical

human model will pave the way for testing patient-specific responses, developing individualized treatments and accelerate their track to the clinic.

1395 The mitoDdCBE System as a Mitochondrial Gene Therapy Approach

Jose Domingo Barrera-Paez[1], Sandra Bacman[1], Till Balla[2], Beverly Mok[3], David R. Liu[3], Danny Nedialkova[2], Carlos T. Moraes[1]

[1]University of Miami, Miami, FL,[2]Max Planck Institute of Biochemistry, Munich, Germany,[3]Broad Institute, Harvard University, and HHMI, Cambridge, MA

Introduction and Methods The mitoDdCBE system is based on a deaminase whose catalytic domain is capable of deaminating cytosine residues in double-stranded, mitochondrial DNA (mtDNA). To test whether base edited mtDNA can be therapeutic, we took advantage of one of the few existing animal models of heteroplasmic mtDNA mutations, the m.5024T mutant mouse. The m.5024T mtDNA mutation disrupts a Watson & Crick (WC) base pair present in the secondary structure of the mitochondrial tRNA alanine ($tRNA^{Ala}$), reducing its half-life. Because the actual mutation ('T') cannot be corrected, we created a second-site suppressor (at position m.5081C>T) to rescue the phenotype of the m.5024C>T mutation. In this model, an m.5081C>U edited base could restore WC base pairing and improve $tRNA^{Ala}$ stability and function (Fig.1). **Results** To test this hypothesis, we designed *in silico* a pair of mitoDdCBEs to target the m.5081C, electroporated the plasmids carrying the two monomers into a 90% m.5024T mutant line. We then treated the cells with 100ng/ml Ethidium Bromide for 30 days to induce mtDNA depletion and subsequent repopulation. After these treatments, cell colonies were isolated and genotyped. Two clones were selected for further characterization as they have either the lowest (~25%) or highest (~70%) levels of editing achieved while being essentially homoplasmic for the m.5024T. Using a digital PCR (dPCR) approach, we determined the levels of retro-transcribed mitochondrial $tRNA^{Ala}$ and $tRNA^{Asn}$. We found that the $tRNA^{Ala}$/$tRNA^{Asn}$ ratio was inversely proportional to the heteroplasmy levels for m.5024T, and that the edit compensates for the mutation in a dose-dependent way (Fig. 2A). Accordingly, western blotting results showed that the steady state levels of two mitochondrial translation-dependent proteins COX1 and NDUFB8, which are lower in mutant cells, were increased by the base editing (Fig. 2B). Next Generation Sequencing data generated using a novel mim-tRNAseq pipeline confirmed an increase in stability in the edited $tRNA^{Ala}$ and showed that aminoacylation was not affected by the original or edited alterations. **Conclusions** We have successfully edited a cytosine in the mouse mtDNA that acts as a second site suppressor for the pathological m.5024C>T. We are further characterizing the biochemical consequences of the edit and we are currently treating mouse tissues *in vivo* with AAV9 vectors. If successful, we would demonstrate, for the first time, that base edited mtDNA can be therapeutic. **Figure 1. Base editing in the mouse mitochondrial tRNA alanine gene.** The mouse mitochondrial $tRNA^{Ala}$ showing the m.5024C>T mutation (G>A in the $tRNA^{Ala}$). This mutation destabilizes the $tRNA^{Ala}$, probably by disrupting the base pairing at the amino acyl stem. The central image illustrates a putative change in the $tRNA^{Ala}$ secondary structure because of the m.5024 mutation. We have edited the m.5081C to a U, thereby restoring the original WC pairing. **Figure 2. Characterization of the phenotypical consecuences of the m.5081U edit.** (A) Based on the genotype of each cell line, we calculated the probability of having tRNA with a WC pair at the target position. Such value, denoted as 'wild-type mtDNA content', is positively co-related with the steady-state ratio of $tRNA^{Ala}$/$tRNA^{Asn}$. (B) The steady state levels of COX1 and NDUFB8 proteins increased the higher the achieved on-target editing was.

1396 Autophagy Induction Improves Dual AAV Vector Efficacy in a Mouse Model of Glycogen Storage Disease Type III

Louisa Jauze[1,2], Mallaury Vie[1,2], Quentin Miagoux[3], Margot Jarrige[3], Patrice Vidal[1,2], Maria del Valle Montalvo-Romeral[1,2], Lucille Rossiaud[1,2,3], Justine Nozi[1,2], Pierre-Romain Le Brun[1], Jeremy Rouillon[1,2], Fanny Collaud[1,2], Emilie Bertil-Froidevaux[1], Christophe Georger[1], Laetitia van Wittenberghe[1], Adeline Miranda[1], Nathalie Daniele[1], Lucile Hoch[3], Xavier Nissan[3], Giuseppe Ronzitti[1,2]

[1]Genethon, Evry, France,[2]Integrare Research Unit UMR_S951, Université Paris-Saclay, Evry, France,[3]CECS, I-STEM, Institute for Stem Cell Therapy and Exploration of Monogenic Diseases, Corbeil-Essonnes, France

Glycogen storage disease type III (GSDIII) is a rare disease due to mutations in the AGL gene encoding for the glycogen debranching enzyme (GDE). GDE deficiency leads to the accumulation of glycogen mainly in liver, heart, and muscles. With aging the metabolic disorder predominant during childhood is overshadowed by the progressive myopathy and cardiac impairment. To date, there is no curative treatment for GSDIII.The 4.6 kb coding sequence of GDE is a major limitation in the clinical translation of a single AAV-based gene therapy for GSDIII. We previously designed two distinct overlapping AAV vectors with a constitutive or a hepatic promoter, each of them driving the production of the full-length GDE cDNA after recombination, leading to the correction of the muscular and the hepatic phenotype in Agl-/- mice, respectively. We developed an overlapping vector with a liver-muscle tandem promoter able to express GDE (AAV-GDE) in both tissues. Although

efficacy was achieved by a month after injection, the correction was lost overtime. To improve efficacy, we evaluated the combination of AAV gene therapy with an FDA-approved autophagy-inducer drug (Drug Inducing Autophagy, DIA). Treatment with AAV-GDE allowed for complete rescue of the liver phenotype but only partial rescue of the muscle impairment 3 months after injection. However, the combination of DIA and AAV-GDE (AAV-GDE-DIA) increased the correction of glycogen accumulation and muscle strength impairment. To understand the different effects in liver and triceps, we then compared the transcriptomics profiles in these tissues. In triceps, the combined AAV-GDE-DIA treatment induced RNA expression pattern more similar to Agl+/+ mice, while AAV-GDE only partially rescued the RNA expression profile. Interestingly, in triceps, the synergic effect of AAV-GDE and DIA corrects the lysosomal pathway impairment. On the contrary, in the liver, both AAV-GDE and the AAV-GDE-DIA led to RNA expression pattern that differs from both the Agl-/- and Agl+/+ mice, suggesting that restoration of GDE in liver may not results in a complete rescue of the pathology. Together, these results demonstrate that correction of both liver and muscle can be achieved by an overlapping vector expressing GDE with a tandem promoter. Long-term confirmation of the efficacy of the combined treatment is required as well as the validation in other models of the disease to evaluate the robustness of our findings an proceed toward the clinical translation.

1397 CRISPR-Cas9-Mediated Correction of *FANCC* Gene Restores Functions of *FANCC*$^{-/-}$ Hematopoietic Stem Progenitor Cells

Le Anh Quynh, Ka-Kui Chan, Wade Clapp, Elizabeth Sierra Potchanant, Ngoc Tung Tran

Wells Center for Pediatric Research, Department of Pediatrics, Indiana School of Medicine, Indianapolis, IN

Fanconi Anemia (FA) is an incurable recessive monogenic disease caused by mutations in any member of the FA pathway. Approximately 90% of disease-associated mutations occur in 3 genes (FANCC, FANCA, and FANCG) of the FA core complex. FA group C patients (FANCC mutations) exhibit typical but more severe symptoms compared to other subtypes. Transplantation of hematopoietic stem cells (HSPCs) is a preferred approach to treat bone marrow failure (BFM) in FA patients. However, the lack of matched donors, the enhanced risk of graft-versus-host disease, and the development of secondary tumors are major clinical concerns. These complications can be avoided by using gene therapy to repair/replace mutated genes in autologous FA patient-derived HSPCs (FA-HSPCs). Our overarching goal is to develop a preclinical model for CRISPR/Cas9-based gene therapy to treat BMF in FA group C patients. To this end, we established a universal gene repair system that can rescue all patients by integrating the *Fancc* cDNA into the endogenous *Fancc* promoter of hematopoietic stem cells. Using CRISPR/cas9 as ribonucleoprotein complex and AAV6 as donor template, we efficiently corrected the *Fancc* gene in *Fancc*$^{-/-}$ mouse HSPCs via the homology-directed repair (HDR) pathway. We restored the expression of the *Fancc* gene at the mRNA level. Of note, we showed that typical defective phenotypes of *Fancc*$^{-/-}$ HSPCs (*i.e.,* reduced colony-forming unit and hypersensitivity to mitomycin C (MMC) treatment) were rescued in corrected stem cells. These encouraging data demonstrate that the HDR pathway is active in *Fancc*$^{-/-}$ HPSCs, and we are able to rescue the functions of defective stem cells using CRISPR/Cas9-mediated HDR. We also generated a surrogate model for human FA group C by knocking out (KO) the *FANCC* gene in healthy CD34^{+} cells. *FANCC*-KO CD34^{+} cells exhibit all the typical phenotypes of FA-HSPCs: high level of DNA damage, hypersensitivity to MMC treatment, and reduced colony-forming capacity. This surrogate model is an extremely useful tool to optimize the gene editing system for correcting FANCC mutations in FA-HSPCs. Of note, we also demonstrated the efficient HDR in these cells under the transient presence of DNA-Pk inhibitor (M3814) that suppresses the non-homologous end-joining pathway. Currently, we are validating functions of corrected stem cells in vivo using animal models and exploiting our Spacer-Nick approach (Tran et al, Science Advances, 2022) for a safer gene editing system to correct *FANCC* mutations. In this approach, we use Cas9 Nickase and two off-set PAM-OUT sgRNAs to generate 2 nicks at both strands of targeting sequences. The distance of the two nicks is ranged from 200-350bp minimizing the on-target mutations. We have demosntrated that the Spacer-Nick system sustains high efficient HDR and mitigates all the adverse genetic effects caused by traditional CRISPR/Cas9 system. Additionally, Spacer-Nick induces minimal DNA damage. Thus this approach is suitable for gene correction in *FANCC*$^{-/-}$ cells that are hypersensitive to DNA damage.

1398 Development of AAV Vectors for LGMDR7 Therapy

Liubov V. Gushchina[1], Adrienne Bradley[2], Gabrielle Dufresne[2], Tatyana Vetter[1], Emma Frair[2], Jacob Lay[2], Natalie Rohan[2], Greg Cox[3], Scot A. Wolfe[4], Charles Emerson[5], Kevin M. Flanigan[1]

[1]Center for Gene Therapy, The Ohio State University and Nationwide Children's Hospital RI, Columbus, OH,[2]Center for Gene Therapy, Nationwide Children's Hospital RI, Columbus, OH,[3]The Jackson Laboratory, Bar Harbor, ME,[4]UMass Chan Medical School, Worcester, MA,[5]Department of Neurology, UMass Chan Medical School, Worcester, MA

Limb girdle muscular dystrophies (LGMD) are progressive, fatal and degenerative genetic disorders. LGMDR7 (formerly known as LGMD2G) is one of the rarest forms of LGMD with autosomal recessive (AR) inheritance affecting both males and females worldwide. LGMDR7 is caused by mutations in the TCAP gene encoding the TCAP (also known as telethonin or T-cap) protein and is characterized by progressive muscle weakness, muscle atrophy, calf hypertrophy, and cardiomyopathy leading to loss of ambulation. There is no cure for patients with LGMDR7. Previously, we developed an rAAV-mediated TCAP construct, the expression of which led to an improvement in the teletoninopathy phenotype and prevented disease progression. Here, we report preliminary data following intramuscular injection of 9-12-week-old humanized TCAPKI-null (hTCAPKI) males and females with several myotrophic rAAV.TCAP vectors. The age matched hTCAPKI and C57Bl/6 mice injected with diluent were used as controls. Treated mice were sacrificed one month post injection to evaluate TCAP protein expression by immunofluorescent (IF) analysis and western blot (WB). Both WB and IF data confirmed a significant restoration of TCAP expression in all vectors. However, hTCAPKI mice treated with muscle-tropic AAV variants showed several folds higher TCAP expression as compared to groups treated with a natural AAV

variant in males and females. These results suggest that myotrophic AAV serotypes could transform the treatment of LGMDR7 patients by significantly reducing vector doses (several logs) and therefore reducing any potential adverse events that can be associated with high AAV doses.

1399 AAV-Mediated Riboswitch-Controlled Delivery of Anti-HER2 Antibody Suppresses HER2-Positive Tumorigenesis

George Wang, Zhaojing Zhong, Jae Gyun Oh, Samuel Waksal, Alexandria Forbes, Xuecui Guo
MeiraGTx, New York, NY

AAV-mediated antibody expression is a promising therapeutic approach to treating many diseases. However, long-term and excessive amount of therapeutic antibodies from unregulated vector may result in unwanted side effects and a narrow therapeutic window, as well as limiting efficacy of gene therapies. Here, we present the development of regulated anti-HER2 antibody gene, whose expression is controlled by riboswitch via small molecule inducer. Different from previously reported gene regulation systems that involve the use of exogenous protein components, our gene expression platform utilizes a riboswitch which is an RNA element that contains an aptamer as a sensor for small molecule ligand/inducer. In the absence of the small molecule inducer *in vitro*, the antibody gene with a riboswitch cassette does not express antibody protein, whereas in the presence of small molecule inducer, antibody is robustly produced in a dose dependent manner. The riboswitch has been built for activity in mammalian cells and results in activation of gene expression from a very low or undetectable basal level in the absence of the small molecule, to therapeutic levels in a tight dose response to the orally delivered small molecule. When the antibody gene with riboswitch was delivered in AAV to the muscle of mice, orally dosed small molecule induced antibody expression in a tight dose response to the small molecule. Upon withdrawal of daily oral dosing of the small molecule antibody expression subsequently diminished and returned to baseline. The efficacy of small molecule induced anti-HER2 antibody was demonstrated *in vivo* in an HER2+ tumor model. $HER2^+$ tumor growth and tumorigenesis was halted following the daily delivery of the oral small molecule in a dose response to the small molecule, rapidly achieving the same level of tumor blockade as constitutively delivered anti-HER2 antibody. Our data indicate that our synthetic mammalian riboswitch works efficiently *in vivo* and can provide precise control of therapeutic antibody expression by controlling the dose of orally administered small molecule. Expression of the regulated HER2 antibody gene is activated in a dose response to oral small molecule achieving high levels of antibody expression and rapid tumor suppression.

1400 AAV9 Capsid Variants with Improved CNS Transduction Identified by Directed Evolution

Marcus Rohovie, Nikki Kruse, Christopher Schmitt, Victoria Wong, Antoinette Sero, Mirella Rivera-Velazquez, Grace Lee, Sarah Desautel, Elizabeth Del Greco, Faezeh Sedighi, Aleksandra Nivina, Stephan Jenne, Kahsay Gebretsadik, Ambuj Kumar, Chinping Chng, Hassibullah Akeefe, Adam Silverman
Codexis, Inc., San Carlos, CA

Many monogenic neurological disorders have no approved disease-modifying treatments, owing in part to the poor efficacy of current gene therapy technologies for central nervous system (CNS) tropism. Current methods to counteract poor transduction rely on CNS-directed dosing, yet standard vectors dosed by intrathecal (IT) and intracisternal magna (ICM) routes do not broadly transduce deeper brain structures and at high doses often cause toxicity. The goal of this study is to develop adeno-associated virus 9 (AAV9) capsid variants that more effectively transduce CNS neurons when delivered directly to the CSF, in order to increase vector distribution throughout the brain and reduce vector-associated toxicity. In this study, we describe the application of the CodeEvolver® directed evolution platform to screen for improved AAV9 variants. CodeEvolver® uses high-throughput transfection for capsid production, in vitro screening using human induced pluripotent stem cell (iPSC)-derived CNS cultures, next-generation sequencing, and machine learning combined with other bioinformatics tools to efficiently explore the sequence space and determine the effect of mutations across the entire AAV9 Cap gene. Our screening approach relies on human ex vivo cellular models, as opposed to the rodent or NHP in vivo selections often used for AAV evolution. Unlike in vivo selections, we obtain comprehensive sequence-structure-function data on nearly all variants and avoid the biases of the enrichment and recovery steps of selections. Over three rounds of iterative evolution, we have screened >4000 unique variants and have identified mutations in the capsid proteins that lead to >10-fold improvements in transduction of CNS cells. We demonstrate these improvements in iPSC-derived forebrain neurons, CNS organoid "minibrain" models, and mice. Our results highlight a new approach to capsid engineering and suggest that screening, as an alternative to selection, may be a viable tool for engineering capsids with enhanced properties.

1401 ScFv Mutagenesis to Mitigate CAR-Mediated Tonic Signaling

Arman Oner[1], Anna-Kristina Kluever[1], Mohamed-Reda Benmebarek[2], Matthias Seifert[1], Bruno L. Cadilha[1], Theo Lorenzini[1], Stefan Endres[1], Sebastian Kobold[1]
[1]Division of Clinical Pharmacology, Department of Medicine IV, Klinikum der Universität München, Munich, Germany,[2]Thoracic and GI Malignancies Branch, National Cancer Institute, Bethesda, MD

Background: In the past decade, chimeric antigen receptor (CAR) T cell therapy has proved to be a valuable tool in our growing armamentarium against cancer, specifically hematologic malignancies. However, efforts to expand this treatment modality into the realm of solid tumors have proved more challenging than initially anticipated. In contrast to hematologic malignancies, solid tumors present numerous tumor-intrinsic obstacles that impede the efficacy of CAR T cell

therapy. In addition, each new target requires the use of a distinct targeting domain, most commonly a single-chain variable fragment (scFv), which poses another set of challenges that are CAR-intrinsic. Although a substantial effort is directed at tackling the tumor-intrinsic obstacles to enable CAR T cell therapy in solid tumors, CAR-intrinsic challenges remain relatively underdiscussed. Arguably, the most important CAR-intrinsic challenge is the ligand-independent basal stimulation resulting from the aggregation of CARs on the cell surface, a phenomenon also known as CAR-mediated tonic signaling. In certain settings, this superfluous signaling has been shown to mimic chronic antigen stimulation and is linked to T cell dysfunction. To date, the most widely adopted strategy to mitigate this issue has been to replace the CD28 costimulatory domain with the 4-1BB domain, which has been shown to result in CAR T cells that are less prone to the deleterious effects of CAR tonic signaling. Crucially, this strategy does not address the problem of CAR aggregation. In this study, we sought to tackle the issue of CAR aggregation through rational mutagenesis of the scFv. **Methods:** An in-silica analysis was used to identify and stabilize potential regions of interest in several publicly available antibodies. ScFvs based on these stabilized antibodies were generated and incorporated into a second-generation CAR construct containing a CD28 costimulatory domain and cloned into a γ-retroviral plasmid by Gibson assembly. Following stimulation, negatively enriched healthy donor T cells were retrovirally transduced with respective CAR constructs and kept in culture for an additional week until immune profiling by flow cytometry and functional assays. Upon profiling, CAR T cells were cocultured with an ovarian carcinoma cell line in an impedance-based real-time cytotoxicity assay. In addition, they were challenged with a variety of recombinant proteins, capable of inducing apoptosis to determine their propensity to enter apoptosis. Throughout the study, an FMC63-derived CD19 targeting CAR and a 14G2a-derived GD2 targeting CAR were used as a negative and positive control, respectively. **Results:** Immune profiling of the scFv-stabilized CAR T cells revealed a less differentiated CAR T cell product while simultaneously demonstrating increased CAR expression on the cell surface, suggesting enhanced stability and diminished CAR-mediated tonic signaling. Additionally, the scFv-stabilized CAR T cells maintained their specificity and demonstrated non-inferiority in their cytotoxic capacity when compared to their non-modified counterparts, as evidenced by a real-time cytotoxicity assay. These findings were further corroborated by their improved resistance to apoptosis when challenged with recombinant proteins. **Conclusion:** Our study suggests that scFv engineering is a viable strategy to stabilize a CAR and curb CAR-mediated tonic signaling. The mutations identified in this work are expected to be broadly applicable to a number of antibody germline families and have the potential to substantially improve the efficacy of CAR T cell therapy by preventing early T cell dysfunction and paving the way for long-term responses.

1402 Point Mutations on Omicron BA.5 Confer Vaccine and Antibody Evasion

Kristen Ngai[1,2], Renee Ngai[1,3], Aaron Lin[1]

[1]Department of Molecular Biology, Princeton University, Princeton, NJ,[2]Science Research, Livingston High School, Livingston, NJ,[3]Livingston High School, Livingston, NJ

The coronavirus is a quickly evolving virus that has been spreading worldwide, causing 600 million cases and 7 million deaths. As population-wide immunity has developed through vaccinations and infections, SARS-CoV-2 will likely mutate to become more immune evasive, which may cause another coronavirus surge. In this study, we aim to examine the origin of the BA.5 variant (a subvariant of Omicron) and how point mutation frequencies of BA.5 changed from January to October of 2022. We aligned 200 BA.5 nucleotide sequences from the NCBI database and identified their mutation frequency percentages. 83% of all BA.5 variants originated from clade 22B. The point mutations within the spike protein, F486V, L452M, and R493Q, are prevalent in 90% of BA.5 variants. The F486V and L452M point mutations were previously reported to decrease the neutralizing activity of immune sera, which allows BA.5 to escape class 2 and class 3 receptor domain binding. Therefore, the use of monoclonal antibody treatments for Omicron might not be as effective. This study helps immunologists create more effective therapeutics against the BA.5 subvariant.

1403 Making and Breaking the Skeletal Muscle Stem Cell Niche

Michael Hicks[1], April D. Pyle[2]

[1]University of California, Irvine, Irvine, CA,[2]UCLA, Los Angeles, CA

Skeletal muscle stem and progenitor cells including those derived from human pluripotent stem cells (hPSCs) offer an avenue towards personalized therapies. Here we demonstrate both stem and progenitor cells readily fuse to form human-mouse myofibers, but skeletal muscle progenitor cells (SMPCs) from hPSCs inefficiently take up position in human-mouse stem cell niches. In contrast, SMPCs expressing the transcription factor PAX7 were 50-fold more likely to associate with a subset of immature human myofibers that resembled fetal niches, 1-2 months after transplantation. We hypothesized lack of SMPC engraftment into the muscle stem cell niche was due to cell competition with endogenous mouse SCs occupying SC niches. Thus, we generated an inducible diphtheria toxin SC ablation mouse model compatible with human engraftment to test this hypothesis. Interestingly, ablation of mouse SCs only increased numbers of immature human myofibers and both PAX7+ SMPCs and SCs now predominantly formed niches with human-only myofibers, instead of residing in chimeric mouse niches, suggesting that cell competition is not the prevailing driver of niche formation. Thus, we profiled SC ablated mice with single nucleus RNA-Seq and identified the absence of a transient myofiber subtype, expressing the fetal actin isoform *Actc1*, that could support Pax7 cells during regeneration. Similarly, the transplanted immature human myofibers strongly expressed ACTC1, and we used spatial RNA-seq to identify key factors driving *de novo* human niche formation, including sarcomere assembly and biosynthesis of fatty acids, improving our ability to support human PAX7 cell repopulation. To demonstrate ACTC1+ myofibers are essential to supporting PAX7 SMPCs, we used CRIPSR/Cas9 to insert a FKBP12-Caspase9 fuse gene in the 3'

end of ACTC1 in hPSCs that were then differentiated into SMPCs and transplanted *in vivo*. Upon Caspase-induced apoptosis, we found a 90% reduction in ACTC1+ myofibers and over a 100-fold decrease in PAX7 cell numbers compared to non-induced engrafted controls. As opposed to other niche systems, where niches are formed by stem cell homing to empty niches, we found that transient regenerating human skeletal muscle is essential to emerging niche formation *in vivo* to support PAX7 cells.

1404 *In Vivo* Expansion of Gene-Targeted Hepatocytes Enables Safe and Durable Transgene Expression

Marco De Giorgi[1], So Hyun Park[2], Ayrea Hurley[1], Lavanya Saxena[2], Mingming Cao[2], Marcel A. Chuecos[1], Christopher Walkey[1], Alexandria M. Doerfler[1], Mia N. Furgurson[1], Sarah Hyde[3], Tyler Chickering[3], Stephanie Lefebvre[3], June Qin[3], Karl-Dimiter Bissig[4], Gang Bao[2], Adam Castoreno[3], Vasant Jadhav[3], William R. Lagor[1]

[1]Integrative Physiology, Baylor College of Medicine, Houston, TX,[2]Bioengineering, Rice University, Houston, TX,[3]Alnylam Pharmaceuticals Inc, Cambridge, MA,[4]Pediatrics, Duke University, Durham, NC

Targeted transgene insertion is a genome editing approach that could permanently correct a broad range of liver disorders. However, the utility of this strategy is currently limited by imprecise and inefficient repair mechanisms. For example, homology directed repair (HDR) requires cell division, generally limiting targeting of adult liver to ~1% of hepatocytes. The goal of this work is to develop a system for selective expansion of gene-targeted hepatocytes using essential genes. Our system consists of: (1) transient conditioning of the liver by knocking down an essential gene, and (2) delivery of an untargetable version of the essential gene in *cis* with the therapeutic transgene. To test this approach, we used AAV vectors to insert an essential gene - fumarylacetoacetate hydrolase (*FAH*) - in tandem with a fluorescent marker (TdTomato) into a highly expressed locus in the liver (*Apoa1*). Mice were injected with AAV8 vectors encoding CRISPR/Cas9 (AAV-CRISPR) and a Donor template (AAV-Donor) with *FAH* and a TdTomato transgene. Monthly injections of N-acetylgalactosamine (GalNac)-modified siRNA targeting murine *Fah* were used as a conditioning agent to deplete untargeted hepatocytes and drive expansion of correctly repaired cells. Four months later, mice receiving the conditioning siRNA showed a dramatic 5-fold increase in the number of TdTomato positive hepatocytes, versus those receiving the viral vectors alone (~16% vs 3%). Selective expansion could be further improved to >25% of hepatocytes by manipulation of tyrosine catabolism with a high protein diet. To evaluate the translatability and long-term safety of this approach, we inserted a human Factor IX (*FIX*) transgene into the *Apoa1* locus. Following genome editing, the mice were injected monthly with the conditioning siRNA for three months, and then followed for 1 year. Mice subjected to the expansion protocol showed sustained FIX expression over 1 year with a ~5-fold increase as compared to CRISPR/Donor-treated mice. Liver conditioning caused only a transient elevation of ALT at early time points (4 to 8 weeks), which fully resolved over time. Histology revealed no evidence of liver toxicity and full reconstitution of Fah expression. Importantly, the expansion protocol did not increase the risk of tumorigenesis. SMRT-seq analysis at the *Apoa1* locus revealed 20- to 50-fold increase of correct HDR-, 5'-HDR/3'-NHEJ- or partial integration of the Donor cassette in mice undergoing selection with the conditioning siRNA. Preliminary NGS data showed a dramatic reduction in the relative frequency of off-target to on-target editing in the mice undergoing selection. Overall, these data demonstrate a favorable safety profile and durable transgene expression with our selective expansion technology.

1405 Comparison of Orthogonal Approaches Reveal a Consistent Innate Immunogenic Signature of AAV Capsids

Mona Motwani[1], Pankaj Agarwal[2], Ernesto Luna[2], Donald Drake[2], Sourav Choudhury[1]

[1]Sanofi, Waltham, MA,[2]Sanofi, Orlando, FL

Success of gene therapy for treatment of rare genetic diseases rely heavily on Adeno-Associated Viral (AAV) vectors that provide many attractive features including tissue specific tropism, transduction of quiescent cells and sustained gene expression. However, immune responses to AAV vectors pose a major challenge to successful clinical translation. The capsid as well as encapsulated transgene trigger activation of both innate and adaptive arms of human immune system. While the adaptive immune responses to AAV triggered by B and T cells have been understood to some extent, innate immune activation is very poorly understood. A major challenge in understanding these immune responses lies in the poor translatability of immune responses observed in clinical trials to an ex-vivo setting. To circumvent this challenge and accurately record innate immune responses, we have developed a novel assay that recapitulates innate immune signature in various human donors in response to administration of various AAV serotypes. We have completed a large multi-month donor-capsid matrix screen in human monocytic dendritic cells (moDCs) from healthy donors with this in-house assay to evaluate capsid responses in immune cells from several human donors. We have also validated our in-house assay with a previously established orthogonal in-vitro "MIMIC®" (Modular IMmune In vitro Construct) system. This module, termed the peripheral tissue equivalent (PTE) construct, is a three-dimensional tissue-engineered endothelial cell/collagen matrix culture system that has been previously used to study innate immune activation and cytokine secretion induced by different agonists, vaccines, and biologics. It can screen several human donors in an unbiased automated manner and uses circulating immune cells of individual donors to capture host innate immune response. From both these methods we can sensitively detect a consistent statistically significant increase in 'signature' cytokines IL-1b, TNFa and IL-6 in cells from different donors that were challenged with varied AAV serotypes. Based on the innate immune activation screens, we observed that some donors "responded" to AAV transduction by releasing cytokines whereas other donors were "non-responders" and did not release cytokine upon AAV treatment. Unexpectedly, given that all AAV serotypes expressed the same transgene, we observe that certain AAV capsids are more innate-immunogenic than other capsids at the same dose. These novel findings provide us an early insight into mechanisms responsible for host innate immune responses to gene therapy vectors and will help us develop strategies to mitigate host reactogenicity to AAVs.

1406 Optimization of AAV Vector Design to Reduce Cross-Packaging and ITR Promoter Activity

Matthew John Guggenbiller[1], Noah Taylor[1], Scott Q. Harper[2]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Ohio State University & Nationwide Children's Hospital, Columbus, OH

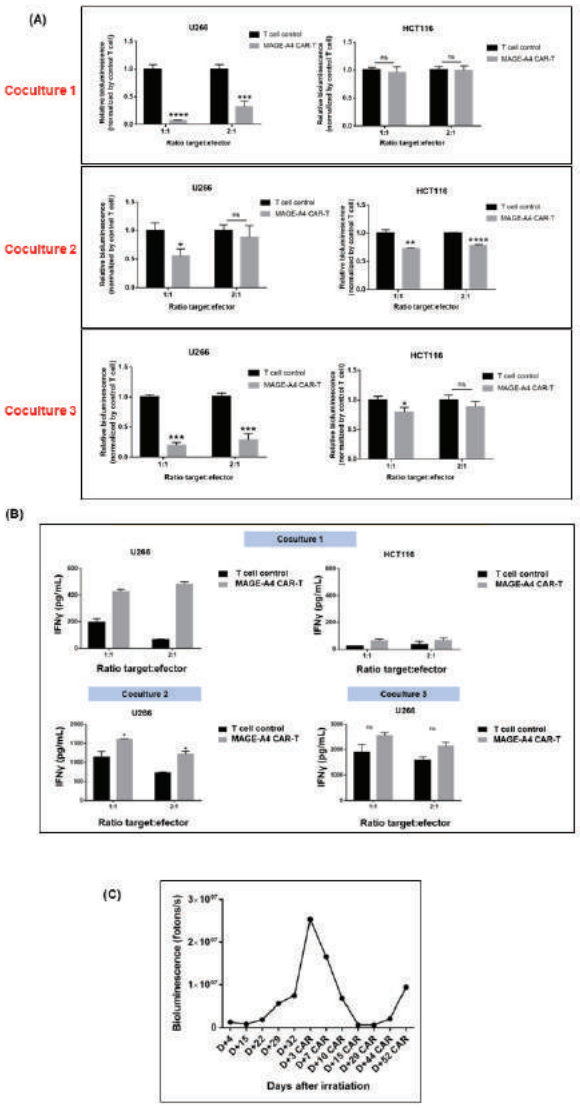
RNAi-based gene therapy is a promising approach to treat dominant genetic disorders. Our lab has developed several AAV vector systems to inhibit genes involved in dominant neuromuscular and neurological diseases which have demonstrated efficacy in pre-clinical animal models. To date, we have not seen evidence of toxicity in rodent models and are working to translate several programs, with next steps including IND-enabling safety and biodistribution studies in larger animal models. With this path to translation in mind, we became concerned with a recent publication showing that AAV-delivered RNAi triggers (artificial, therapeutic miRNAs) were safe and effective in mice but showed toxicity in non-human primate (NHP) brain (PMID: 34663988). This toxicity in NHPs was not related to miRNA expression but instead linked to contaminating cross-packaged material and aberrant transcription driven from vector ITRs. Considering these mechanisms, we set out to (1) assess cross-packaging and ITR promoter activity in our vector systems; and (2) design a new vector that could potentially reduce these unwanted artifacts without impacting titers or payload efficacy. To accomplish these goals, we inserted two large, benign DNA fragments to our self-complementary AAV (scAAV) proviral plasmids, located outside the inverted terminal repeat (ITR) regions. Further, we inserted stop codon sequences in all possible reading frames outside the ITRs to prevent aberrant translation of potential transcripts arising from ITR-driven transcription. To assess ITR promoter activity, we generated a construct containing *Renilla* and *Firefly* luciferase expression constructs in the vector backbone lacking promoters, immediately adjacent to the ITRs. Lastly, to prevent any aberrant influence of ITR promoter activity on our intended vector payload, we added transcriptional repressor binding sites between the ITR and U6 promoters used to drive miRNA expression within the vector genome. Vectors and intermediate control constructs were packaged into AAV2 for in vitro transduction experiments. Vector yields were similar to those achieved by our first-generation system. Using our luciferase reporters, we measured significant promoter activity for both the Δtrs ITR and full-length ITRs present in scAAV vectors. Addition of transcriptional repressor binding sites did not reduce expression of either *Renilla* or *Firefly* luciferase. We are currently assessing the percentage and expression of cross-packaged material after in vitro transduction of our new, intermediate, and original vectors in HEK293 cells via Nanopore sequencing and RNA-seq, respectively.

1407 A New Car Against the Intracellular Target MAGEA4 is Capable of Lysing Multiple Myeloma Cells *In Vitro* and *In Vivo*

Roberta Maraninchi Silveira[1], Izadora Peter Furtado[1], Rafaela Rossetti[1], Daianne Fantacini[2], Andreza Urba[2], Sarah Lima[1], Lev Lev Tsyrenov[3], Hiroshi Shiku[4], Dimas Covas[1], Lucas Souza[1]

[1]Clinical Oncology, Stem Cells and Cell Therapy, University of Sao Paulo, Ribeirao Preto, Brazil,[2]Biotechnology Nucleus of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil,[3]Mie University, Tsu, Japan,[4]Mie University, Tsu, Mie, Japan

Background: Conventional chimeric antigen receptors (CARs) can recognize only cell-surface antigens in their native conformation. This greatly limits the number of suitable targets since most tumor-associated antigens are intracellular. The T cell receptors (TCR) expressed naturally in T cell usually have low binding affinity, and studies demonstrated that artificially increasing of TCR affinity might lead to unwanted binding to self-antigens. **Aims:** In this work, we report the development of CAR-T cells expressing a novel CAR capable of recognizing the intracellular tumor-associated antigen MAGE-A4 presented by HLA-A*02 molecules, which is the most frequent serotype in the western world. MAGE-A4 is a cancer-testis antigen expressed by a wide myriad of neoplasms, including late-stage multiple myeloma (MM). **Methods:** We generated a novel lentiviral vector coding a CAR harboring a recognition domain derived from an antibody specific to a MAGE-A4:HLA-A*02 complex. Next, we produced lentiviral particles and used them to transduce primary T cells. The resulting MAGE-A4/CAR-T cells were cocultured with luciferase-expressing U266 MM cells (MAGE-A4$^+$) or HCT116 colon carcinoma cells (MAGE-A4$^-$) to assess their antineoplastic potential *in vitro*. We also evaluated IFNγ release during coculture and tested the antitumor potential in a MM xenograft model using NSG mice. **Results:** Transduction efficiencies of new MAGE-A4 CAR vector were high, reaching 57% to 84% in two transductions of different donor samples. These transduced cells displayed normal growth *in vitro* and stable expression of the CAR after 14 days of expansion. The percentage of in vitro tumor cell lysis using CAR-T cells derived from three different donors were 50%, 93% and 45%, respectively. Accordingly, CAR-T cells secreted IFNγ during coculture with U266^{luc} cells, but not with HCT116^{luc} cells, confirming the target-specificity. In an aggressive MM xenograft model, we observed that the MAGE-A4/CAR-T cells induced a strong tumor regression in established high-burden MM grafts, followed by relapse of the diseases after two weeks. **Conclusions:** We demonstrated the generation of a novel lentiviral vector coding a fully functional CAR which was able to redirect the cytotoxic activity of T cells against MAGE-A4+HLA-A*02$^+$ MM cells in vitro and in vivo. These results lay the groundwork for the establishment of a novel advanced cell therapy against MM and other MAGE-A4$^+$ malignancies. Figure 1: Panel with results from co-cultures, ELISA assay and *in vivo* pilot experiment. In A, cocultures were made from three samples from different donors. B, co-culture samples were processed by ELISA to analyze IFN release and, C, viral load was analyzed by relative bioluminescence.



1408 High-Throughput Engineering of Logic Gated-Gene Circuits for Precision CAR Cell Therapies

Nicholas Frankel[1], Ippolito Imani Caradonna[1], Marcus A. Gainer[1], Junjie Tony Hua[1], Brian S. Garrison[1], Russell M. Gordley[1], Timothy K. Lu[1,2]

[1]Senti Biosciences, South San Francisco, CA,[2]Massachusetts Institute of Technology, Cambridge, MA

Targeted therapies, including chimeric antigen receptor (CAR)-based cell therapies, can cause toxicity when healthy cells also express the targeted protein, making it difficult to make effective and safe therapies against solid tumors. Using CEA-targeted cell therapies in colorectal cancer, for example, has resulted in colitis due to expression of CEA on healthy colon (Parkhurst et al., Mol. Ther., 2011). To address this central challenge in oncology therapeutics, we aimed to develop an inhibitory CAR (iCAR) that recognizes VSIG2, which we demonstrate is expressed selectively on healthy colon epithelial cells. This iCAR blocks CEA CAR-mediated toxicity, thus maximizing the on-target, on-tumor killing of CEA expressing cancer cells. However, CARs are composed of many domains and thus occupy an extremely large combinatorial design space. Current approaches to CAR engineering involve low-throughput batch testing by hand in a time-consuming manner that may be biased by operator inconsistencies. To overcome these limitations, we created a novel automatic liquid handling process, HEPHAESTUS (High-throughput Engineering Platform with Hands-off Automation that Evaluates Smart Therapies with Unbiased Screening), that accepts microwell plates of CAR constructs in DNA form, produces concentrated virus, transduces primary human NK cells, and sets up performance assays using mixed populations of target "healthy" and "cancer" cells. In this assay, NK cells expressing a gene circuit consisting of an anti-CEA activating CAR and an anti-VSIG2 iCAR tended to kill CEA+ "cancer" target cells more than CEA+VSIG2+ "healthy" target cells. We validated the ability of this platform to evaluate and rank the performance of hundreds of gene circuits with different iCARs in parallel, in one self-contained, concurrent, end-to-end process. Manual validation of optimized iCARs confirmed suppression of up to 98% of killing by anti-CEA-CAR-NK cells against CEA+VSIG2+ "healthy" target cells, without any loss of tumor-killing function against CEA+VSIG2- "cancer" target cells. Automated high throughput screening can therefore be used to optimize gene circuits in primary cells to achieve near-digital logic in precision cell therapies.

1409 A Multi-Dimensional Survey of AAV Tropism in Mice

Christopher J. Walkey[1], Kathy Snow[2], Alexa Martinez[1], Jote T. Bulcha[3], Aaron Cox[4], Cecilia Ljungberg[5], Sean Hartig[6], John R. Seavitt[7], Dan Wang[8], Stephen A. Murray[9], Jason E. Heaney[7], Guangping Gao[10], William R. Lagor[1]

[1]Department of Integrative Physiology, Baylor College of Medicine, Houston, TX,[2]The Jackson Laboratory, Bar Harbor, ME,[3]University of Massachusetts Medical School, Worcester, MA,[4]Department Medicine, Baylor College of Medicine, Houston, TX,[5]Department of Pediatrics, Baylor College of Medicine, Houston, TX,[6]Department of Medicine, Baylor College of Medicine, Houston, TX,[7]Department of Molecular and Human Genetics, Baylor College of Medicine, Houston, TX,[8]Horae Gene Therapy Center and Department of Microbiology and Physiological Systems, University of Massachusetts Medical School, Worcester, MA,[9]The Jackson Laboratory, Bar Harbor, ME,[10]UMass Chan Medical School, Worcester, MA

Adeno-associated viruses (AAVs) have emerged as the leading vector for *in vivo* gene therapy. To expand their utility, it is important to understand the biodistribution and transduction efficiency of different AAV serotypes following delivery. To this end, we undertook a large-scale survey of AAV tropism in mice following systemic administration. AAVs from ten different naturally occurring serotypes of relevance to human gene therapy were examined, including AAV 3b, 4, 5, 6, 7, 8, 9, rh8, rh10, and rh74. Recombinant AAV were packaged to contain a bidirectional transgene cassette for ubiquitous expression of both a ZsGreen fluorescent protein and Cre recombinase. The AAV vectors were tested in"Ai9" reporter mice, which express the tdTomato

fluorescent protein upon Cre-induced recombination. In doing so, we hoped to acquire information about the level of transgene expression (ZsGreen), as well as a highly sensitive means of fate-mapping transduced cells (tdTomato). Multiple mice of both sexes were injected intravenously with 1E12 genome copies of each of the ten serotypes and followed for 4 weeks. A comprehensive panel of 20 tissues (including reproductive organs) from each mouse was prepared for both molecular and histological analysis. To evaluate biodistribution, we quantified vector genome copy number in each organ from every mouse by qPCR. As expected, the majority of AAV serotypes had a strong tropism for the liver. In addition, our data identified several sex differences in transduction efficiency, as well as high tropism of some serotypes in several organs not often considered as targets for AAV transduction. For example, we found that AAV4 strongly transduced lung. Functional tropism analysis by fluorescent imaging has confirmed and extended these results, providing additional information about efficiency of delivery and cell type specific resolution. In addition, a complementary experiment using AAV9 to deliver CRISPR/Cas9 editing reagents demonstrated the adaptability of our approach to genome editing. This work will be publicly available as part of NIH's Somatic Cell Genome Editing (SCGE) initiative, and we anticipate that it will prove to be a valuable resource for researchers aiming to use AAVs to target specific organs and cell types, especially for appropriate selection of capsids in preclinical gene therapy.

1410 Expediting Lentiviral Vector Production with Automated Bioreactors and Design of Experiments

David Ede[1], Finn Watt[2], Stefanie Geiger[2], Andy Kwok[2], Donald Traul[1], Michael Roberto[1], Vincent Lam[1], Erik Chew[1], Marlena Warner[1], Erica Schulze[3], Joshua A. Gustafson[2]

[1]Sartorius, Bohemia, NY,[2]Seattle Children's Therapeutics, Seattle, WA,[3]Sartorius, Goettingen, Germany

Background & Aim: Development of new LV bioprocesses is often slow due to the difficulty in establishing optimal values for critical process parameters and the large time requirement to run analytical assays. The ability to make accurate, data-driven product estimations can greatly speed up development timelines. Therefore, the creation of a new LV upstream production process utilized a scalable bioreactor platform with Ambr®15, BioSTAT STR® 50, and Umetrics® Suite data analytics software. The application of design of experiments (DOE) and multivariate data analytics (MVDA) allowed the rapid development and scaling of the LV production process from 15mL to 50L. **Methods, Results & Conclusion:** LVs were produced in HEK293 cells transiently transfected in a 24-way Ambr®15. Infectious titers were calculated by LV transduction on H9 cells measured via flow cytometry. Experiments made use of DOE methodology in MODDE® to design, optimize, and predict bioreactor and process parameters, with results validated in the BioSTAT STR®. The upstream process was developed in two phases. The first phase selected process parameters for the growth and vector production phases of the bioreactor. The second phase further improved, optimized, and characterized the initial process, and then validated the results in a scale-up study. The process was scaled-up from 15mL directly into 50L using the Process Insights software. This project design allowed for rapid deployment of the process for initial GMP facility operations to happen in tandem with powerful process optimization experiments. Data analytics software applying DOE methodology was leveraged to speed up the development timeline by testing and optimizing multiple factors in each experiment. MVDA was utilized to identify process differences between small- and large-scale productions. First phase titers at 50L scale were comparable to those produced at 15mL, and the final optimized process improved upon the initial results. The use of data-based software enabled rapid development of a new LV manufacturing process by reducing the number of experiments required and direct scale-up from 15mL to 50L.

1411 Introduction of Premature Stop Codons within ATXN2 Repeat Induces Therapeutically Relevant Changes in Expression

Michael Kuckyr[1], Defne A. Amado[1], Beverly L. Davidson[2]

[1]University of Pennsylvania, Philadelphia, PA,[2]Children's Hospital of Philadelphia, Philadelphia, PA

Spinocerebellar Ataxia Type 2 (SCA2) is an autosomal dominant disorder impacting up to 1 in every 50,000 individuals. SCA2 is caused by an extended CAG- repeat within exon 1 of the ATXN2 gene that causes ataxia, dementia, and death. Our lab has observed that excising the repeats or disrupting the gene using AAV delivered CRISPR-Cas9 can result in genomic integration of AAV at the cut site. To avoid this possible genotoxic event, we are utilizing base-editing, which can create single-point mutations without the need for a double strand break. We hypothesize that cytosine base-editing can be used to introduce premature stop codons within the repeat region of ATXN2, which will terminate translation and be therapeutically beneficial by reducing mutant ATXN2 protein and RNA levels. Our data shows that base editing can introduce stop-codons within the repeat of ATXN2 *in-vitro,* achieving 47% DNA editing with a corresponding reduction in 33% of RNA and over 80% reduction of ATXN2 protein levels. Based on these exciting preliminary results, we are moving into SCA2 mice to test if this method can alleviate SCA2 disease phenotypes in mouse models. While there are currently no treatments available for SCA2 patients our work shows the therapeutic potential of base-editing to remedy this disease, and future work will focus on patient derived cells available through the Children's Hospital of Pennsylvania.

1413 Optimization of Nuclease Digestion Unit Operation in a Lentiviral Vector Process for Increased Reduction of DNA Impurities

Jimmy Xin

Process Development, Elevate Bio, Waltham, MA

As the Cell and Gene Therapy (C>) field expands, more and more new innovated therapies and treatments arise. To ensure the safety of these potentially life-changing treatments, one area of focus is around the process-related DNA impurity levels, such as host cell DNA (hcDNA) and plasmid DNA (pDNA), which are typically the concerning process-related impurities for viral vectors. However, due to the complex nature of viral vector production, many factors can inhibit proper reduction of these DNA impurities. Even with the addition of commonly used commercial endonucleases (e.g. Benzonase®),

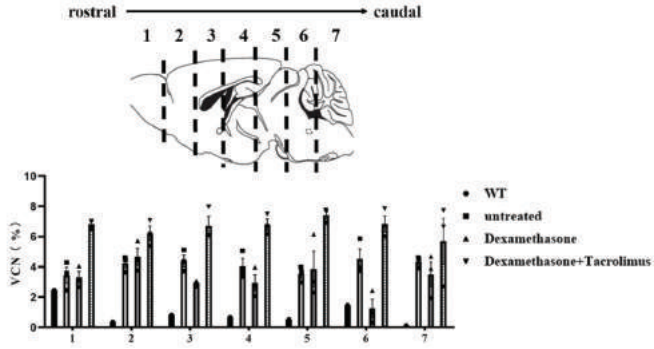
the desired reduction in the DNA levels might not be sufficient to meet process or regulatory recommendations. Here, we provide the statistical analysis results based on several DoE studies for reduction of hcDNA and pDNA levels in our Lentiviral Vector (LVV) platform process, LentiPeak™. Focusing on several critical parameters including nuclease concentration, supplement concentration, incubation time, and incubation conditions (pH and temperature), this data shows the optimal factors and ranges in the nuclease digestion step. In addition, our data characterizes the impact for each significant parameter to identify the relationship toward DNA impurities reduction for both in-process samples and in the final LVV pool to fully understand the carry through impact of the nuclease digestion step. With the increasing need of viral vectors in the C> field, many upstream processes are evolving to meet production demands with higher cell densities and higher plasmid DNA concentrations. This factor, coupled with industry driven prioritization for patient safety, creates a need for processes, especially the nuclease digestion unit operation, to ensure the adequate clearance of DNA impurities. With this data, we hope to highlight the key parameters which support optimal nuclease digestion to be applied to all viral vector processes, and thus streamline the work needed in process development for clearance of the DNA impurities.

1414 Intrathecal Lentiviral Gene Therapy to Treat X-linked Adrenoleukodystrophy Disease

Rui Yang[1], Jie Gong[1,2], Lung-Ji Chang[1,3]

[1]Medicine, University of Electronic Science and Technology of China, Chengdu, China,[2]Medicine, 1Chengdu Women's and Children's Central Hospital, Chengdu, China,[3]Geno-immune Medical Institute, Shenzhen, China

Introduction: X-linked adrenoleukodystrophy (X-ALD) is a genetic disorder due to mutation in the *ABCD1* gene involving defective peroxisomal β-oxidation of very long-chain fatty acids (VLCFAs). The defect leads to the accumulation of VLCFA in organs and tissues, which results in demyelination of central nervous system (CNS) and adrenal cortical atrophy or dysplasia. The current treatment for ALD is hematopoietic stem cell transplantation (HSCT). However, most patients cannot find matched donors, and HSCT is not effective for patients who have already developed symptoms. Gene therapy is a promising treatment for ALD. We hypothesize that direct intrathecal (i.t.) injection of lentiviral (LV) *ABCD1* gene may repair the deficiency. To prevent *in vivo* rejection, an immunosuppressive conditioning treatment was investigated before i.t. injection.**Methods:** An intracerebral LV-*ABCD1* injection gene therapy strategy in dl3/9*ABCD1* KO X-ALD mice has been developed (doi: 10.1038/s41434-022-00355-0). Here we explor an i.t. LV injection technique; each mouse received 50 ul of LV-*ABCD1* (transduction unit $2.3x10^8$) with or without dexamethasone and tacrolimus pre-treatment.**Results:** To establish the feasibility of i.t. LV injection, we first injected trypan blue dye into the fifth and sixth lumbar vertebrae of the wild-type (WT) mice. The results showed the diffusion of dye in both the brain and spinal cord. We next investigated the biodistribution of LV-GFP in WT mice by i.t. injection. The mice were injected with 50 ul of LV-GFP and the vector copy number (VCN) was examined in the peripheral blood (PB), and brain which was divided into 7 equally spaced parts from the rostral to the caudal (S1 to S7), and the spinal cord was divided into cervical, thoracic, and lumbar medulla. The *in vivo* distribution of LV-GFP was determined by q-PCR after 14 days. We detected VCN in three groups of mice: 1) untreated, or pretreated with 2) dexamethasone, 3) dexamethasone plus tacrolimus, and detected VCN in PB, cervical, thoracic, and lumbar medulla as the following: 1) 4.67%, 3.29%, 15.43%, 4.1%; 2) 6.04%, 6.34%, 5%, 11.2%; and 3) 6.45%, 4.95%, 10.07%, 8.13%, respectively. Further, we detected VCN in the brain regions (S1 to S7) of the three groups of mice: untreated, dexamethasone or dexamethasone and tacrolimus treated, as the following: S1) 3.44%, 3.30% and 6.83%; S2) 4.25%, 4.67% and 6.20%; S3) 4.39%, 2.95% and 6.37%; S4) 3.44%, 3.30% and 6.83%; S5) 3.55%, 3.85% and 7.43%; S6) 4.52%, 1.75% and 6.84%; and S7) 4.36%, 3.51% and 5.69%, respectively (see Figure). The above results showed that the LV-GFP could be distributed in the brain, spinal cord, and PB in the untreated group, and there were no significant differences compared with the other groups. Therefore, no pretreatment was done. We injected 2-month-old dl3/9ABCD1 KO mice in foramina of the fifth and sixth lumbar vertebrae with 50 uL of LV-*ABCD1* (treated group) or saline as control. The *in vivo* distribution of LV-*ABCD1* was determined after 22 days. The VCN was examined in the brain, spinal cord and PB as described above, and phenotype correction was evaluated based on established methodology.**Conclusion:** The i.t. injection of LV-GFP *ABCD1* demonstrated transgene biodistribution throughout the CNS as well as the PB and spinal cord *in vivo*. Further characterization of *ABCD1* expression and phenotype correction of i.t. LV-*ABCD1*injection in the dl3/9ABCD1 KO mice will be presented.



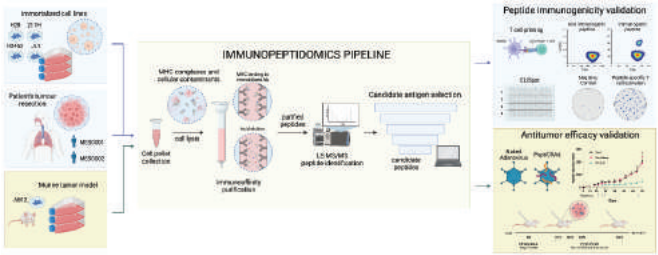
1415 Development of Oncolytic Adenovirus-Based Vaccine for Personalized Treatment of Malignant Mesothelioma

Jacopo Chiaro[1], Gabriella Antignani[1], Sara Feola[1], Michaela Feodoroff[1], Beatriz Martins[1], Hanne Cojoc[2], Valentina Ferrari[3], Daniele Ciampi[3], Ilkka Ilonen[4], Jari Räsänen[4], Mikko Mäyränpää[4], Jukka Partanen[5], Satu Koskela[5], Lukasz Kuryk[2], Salvatore Russo[1], Manlio Fusciello[1], Firas Hamdan[1], Maria Rescigno[3], Mikaela Grönholm[1], Rui Branca[6], Janne Lehtiö[6], Vincenzo Cerullo[1]

[1]University of Helsinki, Helsinki, Finland,[2]Valo therapeutics oy, Helsinki, Finland,[3]Humanitas University, Rozzano, Italy,[4]Helsinki University Hospital, Helsinki, Finland,[5]Finnish Red Cross Blood Service, Helsinki, Finland,[6]Karolinska Institutet, Solna, Sweden

Malignant pleural mesothelioma (MPM) is an aggressive tumor with a poor prognosis. As the available therapeutic options show a lack of

efficacy, novel treatments and therapeutic targets are urgently needed. It has been observed that MPM is responsive to immunotherapeutic cancer treatments, and given its T-cell infiltration, we hypothesized that MPM is a suitable target for therapeutic cancer vaccination.To date, research on mesothelioma has focused on the identification of molecular signatures to better classify and characterize the disease, and little is known about therapeutic targets to engage cytotoxic (CD8+) T cells. In this study, for the first time, we explored the immunopeptidomic antigen-presented landscape of MPM in both murine (AB12 cell line), human cell lines (H28, MSTO-211H, H2452, and JL1), and in patients' primary tumors. Applying state-of-art MHC immuno-affinity purification methodologies, we identified MHC-I-restricted peptides presented on the surface of malignant cells. We characterized some newly discovered patients-derived peptides utilizing in vitro co-culturing techniques, demonstrating that eluted peptides showed promising immunogenicity profiles. Additionally, we provided a proof-of-concept for the application of a whole antigen discovery pipeline using immunopeptidomics for cancer vaccine development in a murine model of MPM. Overall, we investigated the antigen landscape of MPM and showed that the discovered peptides show potential to be used for therapeutic cancer vaccine. (This work is currently under revision in Nature Communication)



1416 Identification of Candidate Biomarkers for Type 1 Diabetes Mellitus by Bioinformatics Analysis of Pooled Microarray Gene Expression Datasets in Gene Expression Omnibus

Kevin Feng[1], Wenqiang Chen[1,2]

[1]Silver Bamboo Health Science, Fairfax, VA,[2]Georgetown University Medical Center, Washington, DC

Background: Type 1 diabetes (T1DM) is a serious threat to childhood life and has a complicated pathogenesis. Currently, molecular mechanisms of T1DM remain largely unclear. The aim of this study was to identify the candidate genes in T1DM by integrated bioinformatics analysis. **Methods:** Transcriptomic datasets (GSE156035) in the GEO database were analyzed for differentially expressed genes (DEGs) using the R statistical language. The differentially expressed genes (DEGs) were identified, and the Gene Ontology (GO) and the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analyses were performed. A protein - protein interaction (PPI) network was applied to screen out the candidate genes. **Results:** The results revealed that 273 DEGs of the three datasets were ascertained in our study, including 135 upregulated genes and 138 downregulated genes. The GO and KEGG enrichment analysis results showed that the functions of DEGs mainly involved in regulation of transcription from RNA polymerase II promoter, specific granule lumen, transcriptional activator activity, Osteoclast differentiation pathway, etc. Through the PPI analysis network, the core genes with the highest degree of 6 nodes were selected: FOS, RHOA, CXCL8, FOSB, EGR1, and DUSP1. **Conclusion:** The genes, identified in this study, may play a vital regulatory role in the occurrence and development of T1DM. Also, they are closely related to obesity and diabetes mellitus. Our results provide novel biomarkers that could be used as representative reference indicators or potential therapeutic targets for T1DM clinical applications.

1417 Scalable Ultrafiltration-Diafiltration UFDF Process of Clarified Plasmid DNA pDNA Using TSeries Cassettes with Omega Membrane

Angel Lorenzo[1], Adam Armengol[2]

[1]Pall Biotech, Westborough, MA,[2]Akron Bio, Sarasota, FL

Plasmid deoxyribonucleic acid (pDNA) is an important genetic engineering tool used to clone and amplify or express genes for a wide range of applications. Production of viral vectors and messenger ribonucleic acid (mRNA) are dependent on pDNA. With the emergence of SARS-CoV-2, the development of novel mRNA/pDNA-based vaccines sped up significantly. The manufacturing process for pDNA poses challenges for process development and for regulatory authorities tasked with assuring quality, efficacy, and safety of the final product. For each process, the design of a suitable purification and concentration strategy will depend on many variables including the pDNA interaction with filtration module and the nature of the pDNA. Following the clarification step, the main objectives of the UF/DF step are to concentrate and buffer exchange the pDNA prior to a chromatography step. One of the challenges for UF/DF step involves plasmid compaction promoted by use of high salt buffers. This compaction can result in pDNA passage through the UF membrane, resulting in low yields. Critical process parameters during these studies were predetermined to avoid plasmid damage due to shear stress. Membrane fouling was prevented, and an effective recovery method was performed, both to avoid yield loss. We have developed a process that confirmed high retention of pDNA, increasing the pDNA yield post-clarification. A Pall Centramate™ cassette with Omega™ polyethersulfone (PES) membrane with a nominal molecular weight cutoff (NMWC) of 100 kiloDaltons (kDa) was used to concentrate and diafilter a clarified pDNA material with ~5 kilobase pairs (kbp) in a high salt buffer and resulted in significant product loss through the membrane. However, using a Pall Centramate cassette with Omega PES membrane with a NMWC of 30 kDa with a plasmid of similar size (~5 kbp), an initial volume concentration factor (VCF) of 10X, a 5 diavolume (DV) buffer exchange and a final concentration to an overall 15X VCF were achieved with no appreciable loss of pDNA product. Both runs were operated at a transmembrane pressure (TMP) of 12.5 psig (860 mbar). The average permeate fluxes for the Omega 30 kDa membrane in Centramate cassette format for the first concentration, the diafiltration, and the final concentration were 80, 80, and 85 LMH, respectively. The UF/DF step achieved the desired buffer conditions for chromatographic loading, provided adequate stability for the in-process intermediate, and had a >95% total pDNA recovery. The development studies presented here confirm Pall UF/DF technology as a highly efficient process solution for pDNA processing after clarification.

1418 Preclinical Specificity and Activity of CABA-201, a Fully Human 41BB Containing CD19 CAR T Therapy for Treatment-Resistant Autoimmune Disease

Binghao J. Peng, Andrea Alvarado, Hangameh Cassim, Ebony Cottman-Thomas, Soprina Guarneri, Ashley Martynchuk, Erica Devitt, Ivan Martinez, Jimmy Perry, Victoria Stratton, Vicky Li, Jonathan Willis, Julia SantaMaria, Sarmistha Banerjee, Tuhina Prasad, Yan Li, Chien-Chung Chen, Gwendolyn K. Binder, Rebecca Dryer-Minnerly, Jinmin Lee, Samik Basu

Cabaletta Bio, Philadelphia, PA

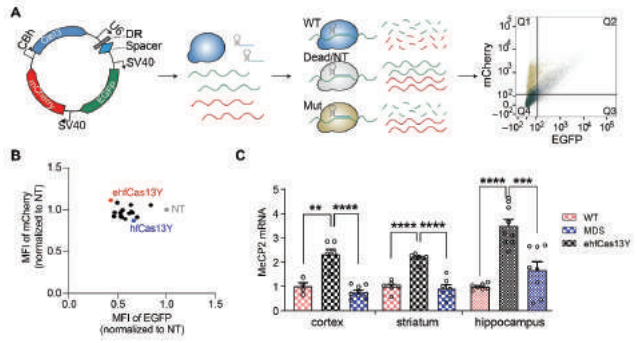
Over 4% of the world population is estimated to live with autoimmune disease. Treatment typically requires systemic immunosuppressive therapy that have associated toxicities and are not curative. There is increasing evidence that B cells play a central role in disease pathogenesis, based upon responsiveness to B cell depletion by antibody-based therapeutics; however, responses are typically transient due to the incomplete depletion of B cells in secondary lymphoid tissue. Chimeric antigen receptor (CAR) T cells are a novel gene-engineered cellular immunotherapy where a synthetic T cell receptor is expressed to redirect the T cell to a desired target. Several B cell targeted CD19 CAR T cell products have led to durable remissions of B cell leukemias and lymphomas; three have been approved by regulators globally, each of which utilizes the murine derived CD19 scFv binding domain FMC63. Data from numerous studies have established the ability of these products to deeply deplete B cells. An early proof of concept pilot study evaluating the safety and efficacy of an FMC63-41BB-CD3ζ CAR T cell product, analogous to one of the approved therapies, in 5 patients with treatment refractory systemic lupus erythematosus suggests the potential to achieve rapid, deep and durable drug-free remissions. We designed a new CD19 CAR T product (CABA-201) containing a clinically de-risked (NCT05091541) fully human CD19 binder (IC78), to minimize immune mediated interference with activity. In addition, the construct utilizes the same 41BB costimulatory domain used in the pilot study above, which is reported to have a reduced incidence and severity of cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) in oncology patients. Preclinical studies were conducted to explore the specificity and activity of CABA-201 compared to the specificity and activity of the FMC63-41BB-CD3ζ construct using the same cell production method. CABA-201 demonstrated comparable cytotoxic activity to FMC63 CAR T cells against $CD19^+$ Nalm6 cells in vitro, and comparable in vivo potency was observed in a dose ranging study in the NSG-Nalm6 tumor model. No evidence of off-target cytotoxic activity of CABA-201 was identified against a panel of selected primary human cells, and no off-target binding against IC78 was detected in a membrane proteome array, or in clinical studies evaluating IC78 in a tandem CAR formation. CABA-201 generated from primary T cells from multiple autoimmune disease patients showed robust CAR surface expression and effective elimination of target autologous $CD19^+$ B cells in vitro. Together, these data support the safety and activity of CABA-201, and provide a clinically relevant benchmark for dose related potency in clinical studies planned for initiation later this year.

1419 Engineered Cas13 with Minimal Collateral Effect and Improved Editing Efficiency for Targeted RNA Degradation

Xing Wang[1], Yingsi Zhou[1], Huawei Tong[1], Dong Yang[1,2], Qingquan Xiao[1], Xue Dong[1], Yuanhua Liu[2], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: The CRISPR-Cas13 family, showing high efficiency and specificity in programmable RNA targeting, has been widely used, and it is a promising approach for transcriptome engineering in basic research and therapeutic applications. However, collateral effects, for example, Cas13 protein degrades bystander RNAs once activated by interaction with the target RNA, have recently been found in drosophilas, mammalian cells, and mammals, hindering *in vivo* application. Previous structural studies have identified the mechanisms underlying collateral RNA degradation. However, to date, it's not clear whether there are any distinct binding sites for the target and nontarget RNA substrates near the catalytic site of activated Cas13 protein. **Methods:** To eliminate the collateral effects of Cas13, we constructed an unbiased screening system with EGFP, mCherry, and an EGFP-targeting gRNA together with each Cas13 variant in one plasmid and used FACS to select variants with high-efficiency on-target degradation (based on low EGFP fluorescence) and low collateral degradation activity (based on high mCherry fluorescence) (Fig. 1A). Based on structural analysis and biochemical characterization of Cas13, we hypothesized that changing the RNA-binding cleft proximal to the RxxxxH catalytic sites in the HEPN domains would selectively reduce promiscuous RNA binding and collateral degradation while maintaining on-target RNA degradation. Thus, we generated a mutagenesis library of Cas13 variants, each containing different one or more random amino acid substitutions (replacing all non-alanine with alanine, X>A, and alanine with valine, A>V). **Results:** After transfecting into HEK293 cells, we obtain several Cas13 variants that exhibited significantly reduced collateral activity, including hfCas13d, hfCas13X, and hfCas13Y, through FACS. The collateral effects revealed by transcriptome-wide RNA sequencing and cell proliferation analysis were also substantially eliminated. However, their endogenous RNA degradation efficiency was also reduced. For better application *in vivo*, we introduced the mutations showing improved cleavage efficiency, into the hfCas13Y protein and finally obtained a new hfCas13Y mutant (ehfCas13Y) with higher efficiency while ensuring low collateral activity (Fig. 1B). To explore *in vivo* therapies, we injected AAV viral particles comprising ehfCas13Y and gRNA targeting human *MECP2* mRNA into a humanized MECP2 duplication syndrome (MDS) mouse model. After 5 weeks, *MECP2* mRNA in the cortex, striatum, and hippocampus is knocked down to close to almost wildtype levels (Fig. 1C). **Conclusions**: The ehfCas13Y protein with minimal collateral effect and high efficiency has great potential for basic research and therapeutic applications for targeted degradation of RNA.



1420 Barcoded Mapping of Promoter Specificity and Efficiency in Human Brain Explants and the Mouse Brain

Aaron M. Mitchell-Dick[1], Michael Adoff[2], Emily J. Kang[1], Derek G. Southwell[3], Aravind Asokan[4]

[1]Surgery, Duke University, Durham, NC,[2]Neurobiology, Duke University, Durham, NC,[3]Neurosurgery, Duke University, Durham, NC,[4]Duke University, Durham, NC

Effective AAV gene therapies warrant a precise combination of capsid and promoter choice to tune therapeutic gene expression and limit off-target effects. To date, selection of AAV capsid and promoter pairs has relied on largely empirical data obtained by evaluating different vectors in preclinical animal models. We generated a barcoded promoter panel driving reporter transgenes and packaged within AAV9 for characterization in murine and human brain tissue. Briefly, the 22 promoters encompass a panel representing ubiquitous promoters, Herpesvirus (HSV)-derived latency associated promoters, as well as 5' upstream sequences of CNS specific genes tagged with barcodes for high throughput RNA sequencing. Following intracerebroventricular injection in mice we observe differences in promoter strength across five distinct brain regions. The Chicken Beta-Actin (CBA) promoter drives the strongest expression compared to Elongation factor 1 alpha (EF1a) and Cytomegalovirus (CMV) promoters. The 5' upstream sequences of human Neuron Specific Enolase (NSE) and S100-beta (S100B) drive highest transcript expression amongst the promoter panel in the mouse neurons and astrocytes, respectively. Further, enabled by an IRB approved protocol following patient surgery for intractable epilepsy, we evaluated the promoter panel in patient-donated, resected cortical tissue. High throughput sequencing data corroborated NSE and S100B as well as HSV-derived promoters for driving strong transcript expression in corresponding cell types. Further, we rank-order promoters of different strengths in both murine and human tissue, providing a roadmap for tailoring promoter selection in potential therapeutic applications.

1421 To Clear or Not to Clear: Interaction between Senescent Cells and the Immune System in HSPC Gene Therapy

Cristina Colleoni, Daniela Cesana, Pierangela Gallina, Laura Rudilosso, Fabrizio Benedicenti, Ivan Merelli, Francesca Sanvito, Eugenio Montini

San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), IRCCS San Raffaele Scientific Institute, Milan, Italy

Preclinical and clinical studies of hematopoietic stem and progenitor cell (HSPC) gene therapy (GT) have shown that the integration of retroviral vectors nearby cancer genes may result in their deregulation, eliciting malignant transformation. Moreover, insertional activation of the *Braf* oncogene by genotoxic vectors in *Cdkn2a*$^{-/-}$ mice resulted in histiocytic sarcoma. BRAF is also known, in its V600E mutated form, to induce hematological disorders in humans (Langerhans Cell Histiocytosis, Erdheim-Chester Disease). We previously showed that BRAFV600E, expressed in human HSPCs transplanted in immune-deficient (NSG) mice, provoked oncogene-induced senescence (OIS). OIS was characterized by cell cycle arrest and aberrant secretion of pro-inflammatory cytokines as a result of the senescence-associated secretory phenotype (SASP). SASP ultimately triggered multi-organ infiltration of histiocytes, lymphoid impairment, and lethal bone marrow failure. Therefore, OIS acts as a double-edged sword: indeed, the secreted SASP factors attract immune cells, favoring the clearance of senescent cells (SCs). However, the chronic release of SASP may generate an inflammatory microenvironment, increasing the risk of comorbidities. Thus, OIS in the context of HSPC GT may pose risks before malignant transformation, by impairing immune cells, inducing oligoclonality, and other signs of early aging of the hematopoietic system. To study the interaction of SCs with immune cells and to identify mechanisms of resilience or clearance of oncogene-expressing cells, we investigated the fate of SCs in the presence or absence of an active immune system. We transplanted wild-type (WT) or NSG mice respectively with WT mouse (m) HSPCs transduced with lentiviral vectors expressing mBrafV600E, an N-truncated version (mBraf trunc), or GFP as control. In NSG recipients, both mBraf trunc and mBrafV600E expression caused dose-dependent lethality, the latter leading to a more aggressive phenotype. Multi-organ histiocytic infiltration occurred in 92% of mice of the mBrafV600E group and 30% of the mBraf trunc group. Instead, in WT recipients, mortality was reduced (only 60%). FACS analysis on peripheral blood and bone marrow samples showed reduced cellularity in both recipients, in particular in B and T cells, with higher impairment in NSG recipients. Interestingly, surviving WT mice of the mBrafV600E group were able to clear SCs, while NSG mice were unable to do so. At the base of this, we observed exacerbated blood plasma levels of CCL-2,-3,-4,-5, IL -2, -6, and -12 in NSG recipients, while in WT recipients only CCL-3,-4, and -5 were increased. Furthermore, transcriptional profiling of sorted myeloid and B cells in NSG and C57 recipients showed different signatures. In NSG recipients, mBrafV600E expression resulted in upregulated TNFα signaling, oxidative stress pathways, apoptosis, and unusual cell cycle inhibitor genes (*Cdkn2d* and *Cdk2ap2*). Downregulated processes were ribosome biogenesis, interferon signaling, MHC class II, and B cell activation. In C57 recipients, in contrast, B cells showed upregulated hallmarks related to cell cycle, DNA repair, and downregulation of apoptotic signaling. This study shows that the immunological background of recipient

mice may favor or impair the efficient elimination of SCs. Future experiments will dissect the specific subset of immune cells responsible for the clearance, with the use of recipient mice with different genetic backgrounds. In the context of HSPC GT, often dealing with immunocompromised patients, our final goal is to identify mechanisms for the elimination of SCs to improve the safety of GT strategies.

1422 Preclinical Trials of an rAAV-Dysf for LGMD R2. Preliminary Results

Ivan Yakovlev[1,2], Alexey Emelin[3], Igor Limaev[3], Konstantin Blagodatskih[4], Alexey Deykin[5], Mikhail Korokin[5], Mikhail Pokrovskiy[5], Sergei Bardakov[1], Artur Isaev[1], Roman Deev[1,3]

[1]Human Stem Cells Institute, Moscow, Russian Federation,[2]Genotarget LLC, Moscow, Russian Federation,[3]Mechnikov North-Western State Medical University, St Petersburg, Russian Federation,[4]Genetico JSC, Moscow, Russian Federation,[5]Belgorod State University, Belgorod, Russian Federation

Introduction. Limb-girdle muscular dystrophy type 2B and Miyoshi myopathy, which are among the most prevalent muscular dystrophies, are caused by mutations in the DYSF gene. There is currently no effective treatment for these diseases. AAV vector gene transfer is a promising approach to treat muscular dystrophies. In this work, we present early preclinical data of AAV-Dysf trials. Methods. In vitro experiment was performed on dysferlin-deficient artificial myoblasts. In vivo experiment was carried out on a sample of 96 mice, 64 of them received AAV-Dysf IM and IV. Muscle samples were obtained from 32 Bla/J (AAV-Dysf) mice 3 months post-delivery. The transgene delivery was confirmed using PCR, RNA detection by RT-PCR, and protein detection by ELISA and immunohistochemistry. A histopathological study with morphometry was performed to assess the necrotic muscle fibers, the proportion of the centrally located nuclei in muscle fibers, and the average cross-sectional area. Physiological tests were performed. Results. All samples were registered with the transgene cDNA, dysferlin mRNA, and dysferlin protein. Also, there were changes in the structure of muscle tissue with regards to the proportion of necrotic, central nuclear muscle fibers and the average cross-sectional area of muscle fiber. Conclusions. It was demonstrated that intravenous and intramuscular administration of a dual AAV vector system carrying 5' and 3' cDNA fragments of the dysferlin gene was able to restore a full-length dysferlin protein, we have registered improvements in physiological tests. In addition to that, muscle tissue structure showed no obvious toxicity.

1423 Non-Replicating, Non-Integrating Vector for Immunotherapy and Vaccine Applications

Jacqueline Fischer-Lougheed[1], Bradford H. Steele[1], Stephanie Lees[1], Cecilia Roh[1], Robert G. Johnson[2]

[1]GenVivo Inc, San Marino, CA,[2]GenVivo Inc, Lafayette, CA

Non-replicating, non-integrating vectors can provide transient expression in proliferating cells and stable transgene expression in quiescent cells. We explored further engineering of our highly modified non-replicating Moloney Murine Leukemia Viral (MoMLV) vector to become non-integrating using our optimized Herpes Simplex Virus Thymidine Kinase (HSV-TK) gene construct as a model system. The optimal vectors for gene delivery should exhibit large payload capacity, high transduction efficiency, target cell selectivity, and no genotoxicity. For cancer therapy and vaccine use, an acceptable immune response is also necessary. Non-integrating vectors will dilute progressively in proliferating cells. However, for certain gene products, transient expression may be sufficient. Additionally, non-integrating vectors in particular offer a reduced risk of genotoxicity. For vaccine applications, transient expression may also be useful. If stable expression in non-dividing cells is required, repeated administration of non-integrating vectors may be considered. In order to generate a non-integrating vector, seven integrase mutants were constructed at the Mg^{2+} binding motif of the catalytic core domain of the integrase in the vector *gagpol* gene: single mutations, dual combinations, and a triple mutant. The constructs were tested by triple transfection of 293T cells with *env*, *gagpol*, and *payload*. None of these mutations affected the physical titer of vector. Using our optimized HSV-TK suicide gene construct as the payload, the level of protein expression was examined in melanoma A375 cells transduced with vectors made with *gagpo*l containing the integrase mutants and compared with payload expression from vectors made with wild-type *gagpol*. Data from FACS and Western blots for HSV-TK protein from the various mutants indicated that early protein expression is strong and nearly comparable to that observed with a functional integrase. This expression correlates well with the cell kill activity in the presence of ganciclovir (GCV). As expected, expression decreased over time to undetectable levels as the cells divided. Lack of integration in the host genome was confirmed using relative integration qPCR. All mutations and their combinations were able to knock out host genome integration. A range of cancer cell lines were tested with the non-integrating vectors. When the cells were successfully transduced with the vectors, HSV-TK expression became undetectable between 7 and 14 days for most of the cell lines tested. This correlated with the loss of cell kill activity in the presence of GCV. To examine the functional effect of the mutated integrase with the reverse transcription deficiency, the reverse transcriptase (RT) gene was also mutated in the *gagpol.* When the mutated RT construct was used in the triple transfection of 293T, the vector particle was produced at a high titer, but transduced A375 cells failed to express the HSV-TK protein. No GCV induced cell killing was observed as well. Not surprisingly, when a combination of integrase mutated and RT mutated vector was tested, expression of the payload was also not present. This implies that RT activity is required even in the non-integrating vector, and that payload RNA alone is insufficient in transduced A375 cells for detectable expression of HSV-TK protein. With non-replicating, non-integrating vectors, there is the opportunity to explore many additional indications in the immunotherapy and vaccine areas. An example is incorporating both an antigen gene and a second gene, e.g., a viral thymidine kinase. Incorporation of both of these genes within a non-replicating, non-integrating vector would permit the combination of antigen production with subsequent GCV-mediated cell killing, with the potential to augment the immune response against the co-delivered antigen.

1424 Development of an Innovative, Scalable, High Productivity Manufacturing Process to Enable Phase I-II Clinical Supply of UX810, an Investigational AAV Gene Therapy for the Potential Treatment of Duchenne Muscular Dystrophy

Jan Thomas Panteli, Cameron Fulco, Wei Xue, Dennis Chen, Chao Huang, Greg Mantenuto, Matt Marrichi, James Warren

Ultragenyx Pharmaceutical Inc., Woburn, MA

Duchenne muscular dystrophy (DMD) is an X-linked recessive, neuromuscular disorder characterized by muscle weakness and atrophy leading to significant developmental motor milestone delays, respiratory and heart failure and premature death. Treating rare neuromuscular genetic disorders with gene therapy requires a significantly higher dose than most other target organs because systemic delivery of product requires widespread distribution to target as many muscle cells as possible. Recombinant adeno associated virus (rAAV) is the leading platform for gene delivery for numerous rare disease therapies, however; high-dosing requirements and low batch yields lead to significantly high costs of manufacturing. There is an urgent need to improve existing rAAV manufacturing platforms to achieve robust, high-yielding, scalable and cost-effective processes to meet high dosing requirements, patient demand, and reduce the overall cost of treatment in order to make therapy accessible to patients. Ultragenyx has developed a cost-effective and scalable rAAV production Pinnacle producer cell-line adenovirus helper platform that eliminates the high cost of goods (COGs) associated with transfection-based processes. In this study, improvement over the legacy batch platform process was demonstrated using intensified manufacturing approaches to achieve greater than 3- fold increase in overall volumetric rAAV yield. Process intensification increased rAAV platform productivity near 1 x10^{12} GC/mL (~1 x10^{15} GC/L) at 250 L scale to enable program development for treatment of DMD. COGs analysis demonstrates this novel platform significantly reduces number of cGMP batches required to initiate Phase I-II clinical studies compared to the legacy process at a significantly reduced cost while meeting high dosing requirements for DMD treatment (Figure 1).

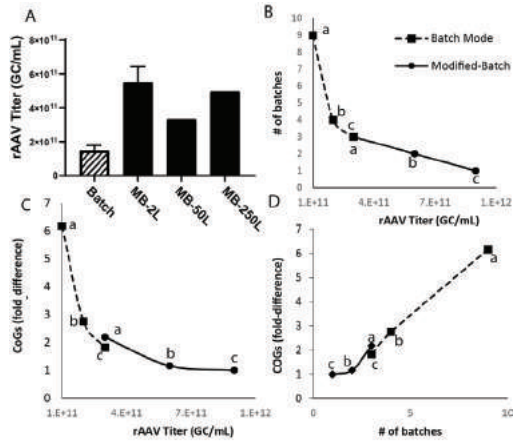


Figure 1. Modified-Batch Yield and COGs Projections for PhI-II DMD Clinical Trial Demand

A) Modified-Batch (MB) rAAV upstream process titer (GC/mL) compared to batch process titer at 2L, 50L, and 250L production shows greater than 3-fold boost in volumetric yield and consitent scaleable performance. **B)** Projection of # of batches needed based on upstream Process Yield for 3 model clones with various specific productivity (a-Low, b- Med, c-high) to support Ph I-II Clincal Trials for DMD using either batch-mode rAAV platform (dashed) vs. new modified-batch perfusion process (solid). **C)** Fold-difference in CoGs projections based on upstream rAAV volumetric yield (GC/mL) for batch (dashed) and modified-batch perfusion process (solid) and **D)** COGs vs. # of batches.

1425 The PS Gene-Editing (PSG) System for Treatment of Lysosomal Diseases

Chester B. Whitley[1], Clifford Steer[2], Michael Przybilla[3]

[1]Gene Therapy Center, University of Minnesota, Minneapolis, MN,[2]Internal Medicine, University of Minnesota, Minneapolis, MN,[3]Pediatrics, University of Minnesota, Minneapolis, MN

Background. The PS Gene-editing (PSG) System is a novel CRISPR-based gene editor that enables lifetime production of therapeutic proteins systemically. The PSG platform has proven safe and efficacious in validated murine models of 4 lysosomal diseases: mucopolysaccharidosis (MPS) type I, Sandhoff and Tay-Sachs diseases, and GM1-gangliosidosis. Program Plan. Toward this goal, the PSG System will be transitioned from AAV delivery to a new formulation of lipid nanoparticles (LNP). In so doing, PSG eliminates the potential for an immunogenic response to capsid epitopes, and eliminates the barrier of pre-existing immunity to AAV, allowing (i) universal targeting regardless of innate immunity or prior exposure to AAV; (ii) repeated dosing; (iii) increased flexibility of payload size; and (iv) anticipated future use for in utero therapy. The LNP delivery vehicle also promises faster production with scalable, vetted GMP-compatible equipment, formulations and processes at reduced cost. In addition, it offers malleable surface characteristics for flexible cell-surface targeting. This program will also implement innovative technology to enhance the PSG gene-editing payload to improve on-target specificity and reduce the risk of off-target genomic insertions. Summary. Since generating the essential preclinical results and participating in the clinical trials (NCT02702115 and NCT03041324) of the first-ever human in vivo gene editing (13-NOV-2017), this program is now at the nexus of (i) decades of bench research and clinical treatment of MPS diseases and other lysosomal conditions; (ii) decades of experience with gene therapy; (iii) evolution of a novel "gain of function" CRISPR-Cas9 PSG System gene editing technology program; and (iv) the cresting wave of LNP technology.

1426 Accurate Integration of piggyBac Transposon into Defined Genome Locus by ACTinG

Naiqing Xu, Xiaohan Hu, Yuan Fang, Jinagxian Liu, Tian Xu

GeCell Therapeutics, Shanghai, China

Gene editing has achieved much advance in the past decade, especially the development of CRISPR-Cas system and its derived tools such as base editors and prime editors. These game-changing tools allow precise gene editing in genome and transform the cell & gene

therapy field. However, precise integration of a large DNA fragment into a specific site of mammalian genome remains challenging. The piggyBac (PB) transposon is widely used to efficiently integrate large cargo into mammalian genome in the "TTAA" dependent manner. PB is almost randomly integrated as it displays little selectivity for particular genome regions. Excision competent yet integration defective (Exc+Int-) PB mutants have little "TTAA" dependent integration. Fusion of Exc+Int- PB mutants to Cas9 takes the advantages of the precision cleavage of Cas9 and the high integration efficiency of PB. We have developed several Exc+Int- PB mutants with high excision but little integration activity in comparison with the WT PB. Fusion of these mutants to Cas9 results in a brand new tool for ACcurate Transposon into Genome (ACTinG) with double strand breaks generated by Cas9-sgRNA cleavage. This tool can efficiently integrate transposon carrying a large cargo (up to 10kb) into a precise genome locus. The integration efficiency is about 4-8 folds higher than that of previous reported Cas9-PBase (R372A_K375A_D450N) and HDR methods. The on-target integration efficiency can be even higher as much as 60% - 80% with a modified donor sequence. These results demonstrate that ACTinG is a robust and efficient tool for precise integration of large DNA cargos into mammalian genome. Further characterization and optimization of this gene editing tool will potentially increase its therapeutic value in different areas.

1427 Bioengineered AAV3B Capsid with Improved Human Hepatocyte Tropism and Evasion of Pre-Existing Neutralizing Antibodies

Jyoti Rana[1], Damien Marsic[2], Chenhui Zou[3], Maite Munoz-Melero[1], Xin Li[1], Oleksandr Kondratov[4], Ning Li[1], Ype P. de Jong[3], Sergei Zolotukhin[4], Moanaro Biswas[1]

[1]IUPUI, Indianapolis, IN,[2]Porton Biologics, Jiangsu, China,[3]Weill Cornell Medicine, New York, NY,[4]University of Florida, Gainesville, FL

Adeno associated virus (AAV) vectors are versatile gene delivery vehicles due to their low genetic complexity. Ongoing research is focused on lowering the overall vector dose, eluding pre-existing neutralizing antibodies (NAb) and improving tissue tropism. Previously, we generated an AAV3B combinatorial capsid library by integrating rational design with directed evolution and identified an isolate, AAV3-DE5, with significantly improved hepatotropism over 5 rounds of iterative selection in hepatocyte spheroid cultures. In this work, we reanalyzed the original dataset to isolate variants from earlier (1-3) iterations based on the assumption that variants with faster replication kinetics might not necessarily be the most efficient at transducing the cell of interest. We identified two new variants: V04 (mutation in VR-IV) and V05 (mutations in VR-IV to VR-VII) with an enrichment score greater than 1. The region from amino acids 351-570, which include mutation regions VR-IV through VR-VII was then synthesized and cloned into the parent AAV3B capsid backbone. In vitro, AAV3B-V04 transduced human hepatocellular carcinoma (HUH-7) cells or mouse passaged primary human hepatocytes (mpPHH) at significantly greater frequencies as compared to AAV3B, AAV3V-DE5, or AAV3B-V05, indicating improved hepatotropism. Similarly, in vivo, AAV3B-V04 transduced human hepatocytes in huFNRG mice at significant frequencies as compared to other engineered variants such as AAV3B-ST or AAV3B-DE5, with high detargeting of mouse hepatocytes. Human hepatocyte transduction efficacy in huFNRG mice was 5-14% for AAV3B-ST, 10-27% for AAV3B-DE5, and 16-35% for AAV3B-V04. Next, we tested the effect of pre-existing NAbs on the efficacy of AAV3B-V04 transduction using IVIg or individual serum samples from healthy donors. The average IVIg concentration required to neutralize transduction by 50% (IC_{50}) for AAV3B, AAV3B-DE5 and AAV3B-V04 was 38, 115.6 and 256 μg/mL respectively, with an observed 6.7-fold- increase in IC_{50} for AAV3B-V04 over the parent AAV3B capsid. Of the 30 human serum samples with detectable (>1:5) NAb titers to AAV3B and AAV3B-DE5, we observed a substantial reduction in reciprocal NAb titers, that were on average 4-fold and 3-fold lower for AAV3B-V04 as compared to AAV3B or AAV3B-DE5, respectively, indicating significant NAb evasion by AAV3B-V04. Of note, in 6 serum samples with undetectable NAbs to AAV3B or AAV3-DE5, we did not detect NAbs to AAV3B-V04, demonstrating that no new immunogenic epitopes were created in the library selection for AAV3B-V04. In summary, AAV3B-V04 demonstrates improved transduction efficiency and reduced immunogenicity as compared to the parent AAV3B capsid and previously described AAV3B-DE5 and AAV3B-ST variants. Since the liver is an important target for gene delivery in many gene therapy applications, AAV3B-V04 as a vector offers high potential to explore translational liver gene therapy studies

1428 Comparative Analysis of Second Strand Synthesis Processes to Establish an rAAV Batch Quality Pipeline Using Nanopore Sequencing

Rebecca C. Feiner, Kathrin Breunig, Florian Dunker, Markus Hörer

Ascend GCTx, Martinsried, Germany

During recombinant AAV (rAAV) production for therapeutic use in gene therapy, the vast majority of encapsidated DNA consists of the correct, full-length vector genome cassette or fragments thereof. However, undesired impurities derived from production plasmids or host cell genomic DNA can become encapsidated in a small but not insignificant proportion of capsids. The comprehensive analysis of encapsidated DNA is key for understanding safety and efficacy of an rAAV batch and to identify weak spots in the genome or in the manufacturing platform. Quantitative polymerase chain reaction (qPCR) or droplet digital PCR (ddPCR) remain the standard for DNA quantification of both vector genome and DNA impurities, but these methods require sequence specific primers that result in selective collection of information regarding encapsidated impurities. Furthermore, these methods provide only very limited information about functionality of DNA, such as length or sequence integrity. Next-generation sequencing (NGS) is an important advancement as it does not require *a priori* sequence information. Long-read NGS technologies, such as nanopore and single molecule, real-time (SMRT) sequencing, can provide reads of several kilo- to megabases originating from a single DNA molecule. Therefore, long-read technologies offer the unique opportunity to collect length and sequence integrity information on encapsidated single-stranded (ss) AAV genomes but also on other encapsidated impurities derived from the production platform. A remaining challenge is that current NGS techniques require double-stranded (ds) DNA as input for sequencing library preparation, whereas AAV genomes and packaged impurities are ssDNA molecules. Different

approaches have been described to convert these ssDNA molecules into dsDNA molecules. The simplest method is the extraction of encapsidated DNA and annealing of complementary (+) and (-) strands. However, efficient performance of this method depends on having abundant packaged (+) and (-) strand sequences for a given DNA segment, generating a bias towards reads of the vector genome cassette or major plasmid derived impurities. Minor impurities such as randomly packaged host cell DNA and/or plasmid-derived sequences might not anneal to form dsDNA required for sequencing adapter ligation and as a result are lost during sequencing library preparation. To this end, a dedicated second strand synthesis step is mandatory to characterize encapsidated DNA impurities by NGS in an unbiased way. We examined different processes to generate material that is amenable for NGS library preparation and tested it with the latest available nanopore sequencing chemistry with improved read quality. Results showed that a robust second strand synthesis can be achieved using random primers and different enzyme classes. We have performed control experiments using synthesized ssDNA without annealing potential to show that dsDNA is generated regardless of the sequence length and complexity. We also focused on the challenging structure of the inverted terminal repeats (ITRs) and elucidated their impact on the second strand synthesis process. This work highlights the importance of the dsDNA library preparation and quality control process to avoid generation of data artifacts that may lead to misleading conclusions.

1429 Targeted Integration to Endogenous Sites in the Human Genome Using CRISPR-Associated Transposases Discovered from Natural Environments

Jason Liu[1], Daniela S. A. Goltsman[1], Lisa Alexander[1], Khak Khak Khayi[1], Christine A. Romano[1], Morayma Temoche-Diaz[1], Shailaja Chadha[1], Rodrigo Fregoso-Ocampo[1], Jennifer Hong[1], Owen P. Janson[1], Liliana Gonzalez-Osorio[1], Sarah Laperriere[1], Keirstinne Turcios[1], Audra E. Devoto[1], Cindy Castelle[2], Cristina N. Butterfield[1], Brian C. Thomas[3], Gregory J. Cost[1], Christopher T. Brown[1]

[1]Metagenomi, Emeryville, CA,[2]Metagenomi, San Francisco, CA,[3]Metagenomi.Co, Emeryville, CA

Integration of DNA into targeted genomic sites has historically been a challenge for therapeutic gene editing. Established transposase and lentiviral systems are efficient at inserting large DNA cargos into the human genome, but result in non-specific and sometimes hyperactive integration. These integrations have resulted in severe adverse events during clinical trials in the form of neoplasia. CRISPR associated transposases (CAST) are a potential solution to this problem, as they could provide user-directed and programmable DNA integration. Although relatively rare in nature, the handful of known CAST systems are efficient at delivering large DNA payloads into bacterial genomes; however, translation to mammalian cells has not been possible. We hypothesized that novel CAST identified from metagenomic sequences of environmental samples would enable discovery of systems more amenable to use in human cells. Mining of millions of assembly-driven, metagenomic sequences from diverse environments uncovered active CAST capable of efficient transposition in vitro and into the E. coli genome. When delivered to mammalian cells, these CAST components are expressed in an active form and localized to the nucleus. When tested in cells, we reproducibly achieved programmable transposition into multiple endogenous sites in the human genome. Our results augur well for the development of CAST into tools for treatment of genetic disease.

1430 Development of PSMA-Targeted Oncolytic Adenovirus for Treatment of Prostate Cancer

Mizuho Sato-Dahlman, Praveensingh B. Hajeri, Kari Jacobsen, Chikako Yanagiba, Masato Yamamoto

Surgery, University of Minnesota, Minneapolis, MN

Prostate specific membrane antigen (PSMA) is highly expressed in poorly differentiated, metastatic, and castration-resistant prostate cancer. It is therefore reasonable to develop a PSMA-targeting therapy for prostate cancer treatment. Oncolytic adenovirus (OAd) is a promising candidate of cancer therapeutics, but many cancer cells are resistant to wild-type OAd infection due to the low expression of adenovirus primary receptor (coxsackie-adenovirus receptor, CAR). In addition, CAR binding of the OAd causes a variety of issues such as toxicity in and sequestration by CAR-positive organs (e.g. liver, lung). Vector retargeting is therefore necessary for adenovirus based transduction of most PSMA positive cancer cells. To generate the cancer-targeting OAd, we have previously established a system for isolating transductionally-targeted infectivity-selective adenovirus by Ad-based library screening approach. Here, we isolated the PSMA-targeted OAd by using *in vivo* Ad-based library screening, and tested the oncolytic activity of the PSMA-targeted OAd. PSMA-targeted OAd (PSMA-OAd) showed strong binding to PSMA-positive cells (HEK293-PSMA and CWR22R (PSMA (+) human prostate cancer cell line)), not to PSMA-negative cells (parental 293 and PC3 (PSMA (-) prostate cancer cell line)). In addition, the anti-PSMA antibody inhibited the binding of the PSMA-OAd, and also RNAi-based PSMA knockdown cells showed weak viral binding compared to a parental cells. For the oncolytic activity, the PSMA-OAd showed strong oncolysis selectively in PSMA-positive cells. In order to assess the *in vivo* function of PSMA-OAd, we assessed *in vivo* viral distribution after intravenous injection (i.v.). We measured the virus copy number in major organs (lung, liver, spleen, kidney, intestine, and tumor) after i.v. injection of the viruses. The PSMA-OAd showed reduced liver and lung targeting compared to untargeted OAd (Ad5-WT). Next, we tested the anti-tumor efficacy of PSMA-OAd. After intravenous administration of the viruses, only the PSMA-OAd showed significant antitumor effect compared to the untreated group ($p<0.05$), while the growth of Ad5-WT virus injected group was same as untreated group. In this study, PSMA-OAd exhibited selective infectivity and oncolysis to PSMA-positive cells, and also systemically injected PSMA-OAd showed remarkable anti-tumor effect. Our results suggest that the PSMA-OAd can embody efficient systemic treatment for metastatic prostate cancer.

1431 Assessment of Investigational Gene Therapy and Gene Editing Program Sponsor Compliance with Twenty-First Century Cures Act and 42 CFR Part 11 Reporting Requirements

Rafael D. Escandon[1], John Massarelli[2], Cara Hunt[2]

[1]DGBI Consulting LLC, Bainbridge Island, WA,[2]Division of Medical Ethics, NYU Grossman School of Medicine, New York, NY

The 21st Century Cures Act, passed in 2016, established a requirement for US sponsors of investigational treatments to create public-facing statements regarding pre-approval access to their investigational product. Once Phase 2 trials are initiated, each company's policy for access must be made publicly available, typically on the sponsor's corporate website. Similarly, in 2017, under 42 CFR Part 11, a requirement for posting study results to the ClinicalTrials.gov website within one year of study completion was initiated. Because investigational Gene Replacement Therapies (GT) and Gene Editing (GE) programs generally produce less clinical trial material than small molecules and biologics, it is unknown whether these limitations of supply impact pre-approval access. Similarly, because long-term safety and durability of efficacy for GT and GE programs are typically assessed beginning in first in human trials, it is also unknown whether sponsoring companies report, or are capable of reporting, meaningful results to clinicaltrials.gov within one year of completion of dose-finding in Phase 1, First in Human (FIH) Studies. **Materials and Methods**: Structured electronic searches of the ClinicalTrials.gov trial repository for active and completed Phase 2 trials with investigational GT and GE products will be conducted a maximum of 60 days prior to presentation. For GT and GE programs in Phase 2 development, searches of all sponsoring company websites for statements regarding pre-approval access, will be conducted and results reported. Structured searches for all applicable and completed GT and GE trials noted in clinicaltrials.gov will be conducted and the presence or absence of posted results within 12 months of the posted completion date, in compliance with the 2016 and 2017 laws, respectively, will be determined. **Results**: Frequencies of investigational GT and GE trial sponsor compliance with the 21st Century Cures Act and 42 CFR Part 11 results reporting requirements will be summarized. Descriptive statistics will be reported for all non-categorical variables, and any relationships identified by therapeutic modality, indication, adult or pediatric age, rare/orphan status, study phase, and public or private funding. **Conclusions**: Proposed based on observed results.

1432 EVADER Reduces Immunogenic Response to AAV8-FIX Capsid

Awilda Rosario, Kara Paolilli, Michael S. Levinson, Carolina Ceballos Diaz, Esmeralda Segura-Zarate, Alaknanda Mishra, Monica Miller, Alan Belicha, Paul A. Fitzpatrick, Genine Winslow

Chameleon Biosciences, Berkeley, CA

We have previously shown that we were able to get greater gene transfer and Factor IX expression using our EVADER-AAV8-FIX treatment in mice and non-human primates. We have done further analysis on the NHP study by taking terminal (Day 78) PBMCs and performing ELISPOT analysis after stimulation of the isolated PBMCs with AAV8 peptides. At the 5E10 vg/kg dose level, there was a 7-fold drop in IL6 producing cells after a single dose and a 3-fold drop after two dose administrations when comparing standard AAV to EVADER AAV. At the 5E10 vg/kg dose level, there was a 3-fold drop in TNFα producing cells after a single dose and a statistically insignificant 1.3-fold drop after two dose administrations when comparing standard AAV to EVADER AAV. There was an even more dramatic drop in doubly positive IL6/TNFα cells of 11-fold at the single dose administration. There was a trend to a 5-fold drop in the double dose administration group (but not significant due to high variability). The enhanced effect of the doubly positive IL6/TNFα cells suggest a synergistic effect of these two cytokines. Further studies will sample PBMCs at different time points for higher resolution mechanistic analysis and may suggest ideal timing between dose administrations. Interestingly, it was shown that anti-capsid Nabs were not significantly reduced by EVADER despite the impact on cytokines as well as seeing additional vector genomes delivered with a second dose. Analysis revealed that huCTLA-4 content on EVADER vector used in the NHP study was dosed at 0.05 ng/kg which was 3 logs lower than muCTLA-4 levels on EVADER vectors in our mouse studies (which was dosed at 70 ng/kg). Abatacept, a soluble version of CTLA-4, is used to treat Rheumatoid Arthritis and reduces patient antibodies. Indeed, Takeda showed that Abatacept, co-administered with the same AAV8-human FIX vector used in our studies, significantly reduced anti-capsid antibodies. Therefore, increasing CTLA-4 levels on EVADER vector batches used for future NHP studies may prove beneficial. CTLA-4 levels on EVADER particles are related to the amount of CTLA-4 protein on the surface of producer cells. In its native role, CTLA-4 is internalized in T cells in response to T cell activation. In our experience, murine CTLA-4 used to make EVADER particles for our mouse studies did not appear to internalize. Human CTLA-4 however does seem to be internalized in HEK293 producer cells resulting in reduced human CTLA-4 on EVADER. Using different strategies, we were able to increase human CTLA-4 levels in EVADER by 2 logs by changing our manufacturing process.

1433 AAV-Mediated, Small Molecule-Riboswitch-Controlled Delivery of Growth Hormone Rescues Growth in GH-Deficient *B.little* Mice

Jae Gyun Oh[1], Zhaojing Zhong[1], George Wang[2], Samuel Waksal[1], Alexandria Forbes[1], Xuecui Guo[1]

[1]MeiraGTx, New York, NY,[2]MeiraGtx, New York, NY

AAV-mediated gene transfer is a promising therapy for many diseases. However, excessive amounts of therapeutic protein—especially hormones or growth factors—expressed from unregulated vectors may result in unwanted side effects and a narrow therapeutic window, as well as limiting efficacy of gene therapy. Here, we present the development of precisely regulated human growth hormone gene, whose expression is controlled by a splicing-based riboswitch via small molecule inducer. Different from previously reported gene regulation systems that involve using exogenous protein components, our gene expression platform utilizes a riboswitch which is an RNA element that contains an aptamer as a sensor for a small molecule ligand/inducer. The riboswitch has been built for activity in mammalian cells and results in activation of gene expression from a very low or undetectable basal level in the absence of

the small molecule, to therapeutic levels in a tight dose response to the orally delivered small molecule. In the absence of the small molecule inducer *in vitro*, the growth hormone (GH) gene with the riboswitch does not express growth hormone protein. In the presence of the small molecule inducer, growth hormone is robustly produced in an inducer dose-dependent manner. When the growth hormone gene with riboswitch was delivered in AAV into the muscle of growth hormone deficient *B.little* mice via local intramuscular injection, the oral small molecule inducer treatment resulted in increased body weight and body length of the mice. The improvement of the animal growth in *B.little* mice indicates that the induction of expression of growth hormone achieves therapeutic level in these animals and demonstrates for the first time rescue of GH deficiency via the delivery of a small molecule inducer of a locally delivered gene therapy. Our data provide evidence that our riboswitch platform provides efficacious and safe gene therapy for delivering GH via gene expression control.

1434 LentiVEX™ Producer Cell Lines: Transfection-Free Production of Lentiviral Vectors Encoding Therapeutically Relevant Transgenes

Matthew Tridgett, Marie Mulet, Sherin Parokkaran Johny, Maria Ababi, Meenakshi Raghunath, Chloe Fustinoni, Richard Parker-Manuel, Corinne Branciaroli, Maria Patricio, Qian Liu, Ryan Cawood

OXGENE, Oxford, United Kingdom

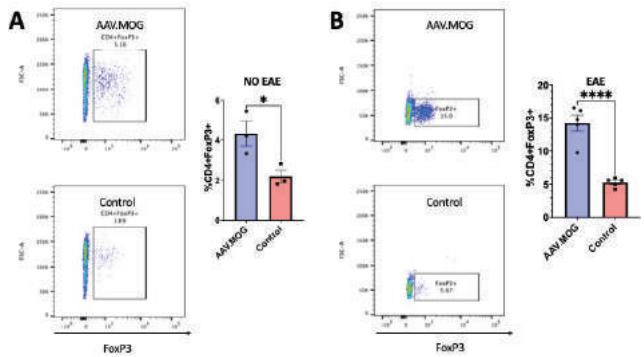
Lentiviral vectors (LVV) are of increasing interest in cell and gene therapy, but high costs and variable vector manufacturing process continue to limit patient access. We thus developed LVV producer cell lines that reduce vector manufacturing cost and process variability as they do not require plasmid preparation, testing or transfection for production of LVV. We first developed an LVV packaging cell line by random integration of Tet-regulated VSV-G and Gag-Pol, and constitutive Rev (codon optimised and regions of DNA homology deleted to decrease risk of recombination) into clonal WXATUS0028 suspension HEK 293 cell line, followed by clonal isolation of the top performing clone. We then developed an LVV producer cell line by transposon-facilitated integration of LVV genome into the top packaging cell line clone, followed by clonal isolation and performance screening. The top clonal producer cell line encoding EGFP produced LVV up to 4.6 $\times 10^8$ TU/mL. Furthermore, we trialled development of LVV producer cells encoding several different therapeutically relevant transgenes, and all producer cells yielded comparable or higher LVV titres than the four-plasmid transfection-based production. Further research work is ongoing to achieve transgene repression in producer cell lines to minimise any transgene impact on the producer cells and thus to maximise LVV titre. In summary, LentiVEX producer cell lines produce LVV at titres comparable to the industry standard four-plasmid method, and reduce manufacturing costs and process variability, improving patient access to LVV-based cell and gene therapies.

1435 Induction of Tregs in the Liver as a Result of Hepatic Gene Transfer is Unhindered by Chronic Autoimmunity

Kevin G. Senior, Daniel Min, Geoffrey D. Keeler, Cristina D. Gaddie, Brad E. Hoffman

Department of Pediatrics, University of Florida College of Medicine, Gainesville, FL

Adeno-associated viral (AAV) gene therapy has opened the door to treating a multitude of genetic diseases through its capability to target specific tissues for expression of a missing or corrected protein. Liver-directed gene therapy has been utilized as a method to treat Hemophilia B as well as the mouse model of Multiple Sclerosis, Experimental Autoimmune Encephalomyelitis (EAE); the latter of which is a result of the generation of transgene-specific $CD4^+FoxP3^+$ T regulatory cells (Tregs) capable of ameliorating disease. Previous work has showcased that early intervention of EAE with a viral vector carrying the sequence for the full-length myelin oligodendrocyte glycoprotein (MOG) reduces clinical and pathological severity of the disease; however, when this novel immunotherapy is given at the chronic/late stage of disease, there appears to be no therapeutic benefit. We hypothesize that Treg generation brought on by hepatic gene transfer has been abrogated as a result of EAE. Two experiments were conducted to determine the validity of this hypothesis. The first involved administering AAV.MOG or control to C57BL/6 (B6) mice and, after at least two weeks, harvesting their spleens and livers to analyze the frequencies Tregs within those organs. In the second experiment, B6 mice were afflicted with MOG_{35-55} EAE and were treated with AAV.MOG or control 30 days after disease induction. Treg frequencies in blood, spleens, and livers were examined two weeks after vector administration. Sections of liver were taken for Western Blot analysis from both experiments to confirm MOG expression. In mice that were not afflicted with EAE, there were no significant differences of Treg frequencies in the blood or spleens of both groups. In accordance with established literature, there was a significantly higher frequency of Tregs in the livers of mice given AAV.MOG as compared to the controls (Figure 1A). Interestingly, in mice that underwent EAE induction, Treg frequencies were significantly increased in both the livers (Figure 1B) and blood of AAV.MOG-vectored mice, indicating that EAE has not prevented that process. There was no significant difference of Treg frequencies in the spleens of either group. Clinical scores between the AAV.MOG and control groups showed no difference in EAE severity. In summary, EAE does not stop the induction of Tregs after liver-directed gene therapy as indicated by the significantly increased frequencies of $CD4^+FoxP3^+$ cells in mice treated with our therapy.



1436 Development of a Next-Generation AAV Helper Plasmid with Improved AAV9 Productivity

Lily Leveque-Eichhorn, Jinna Brim, Isha Ukani, Francis Grafton, Mo Mandegar, Chris Reid
Innovation Hub, Ascend GCTx, San Francisco, CA

rAAV vectors have proven to be safe and effective at delivering genetic material to patients. To date, rAAV has mainly been used to treat rare monogenic disorders. To broaden its use, current production methods must be improved to reduce costs and enhance functional titers. Many manufacturing platforms rely on transient transfection of a helper plasmid containing adenoviral genes E4, E2A and VA-RNA to mediate AAV replication. Whilst this construct can produce functional vector, little work has been done to optimize the combination of viral elements in order to maximize AAV production. We used the ATLAS (Arrayed Targeted Library for AAV Screening) platform to perform a high-throughput screen of a library of viral elements evaluating individualistic as well as combinational effects of these viral genes on AAV9 production. Targets from this screen were incorporated into our minimal helper construct and resulted in >5-fold increase in AAV9 production compared to the industry standard vector. We have confirmed this novel helper construct improves both the potency and yield of AAV9 with multiple cassettes. Studies are underway to evaluate the utility of this construct in multiple AAV serotypes and in a large-scale bioreactor system.

1437 Correction of Diverse Factor 8 Mutations by AAVHSC Genome Editing

Swati Bijlani, Lakshmi V. Bugga, Ka Ming Pang, Luis Manuel Sanchez, Saswati Chatterjee
City of Hope, Duarte, CA

Hemophilia A (HA) results from diverse mutations of the Factor 8 (F8) gene, leading to an inability to form blood clots. Apart from approximately 45% of cases due to Intron 22 inversion (I22I), more than 3000 unique mutations of the F8 gene have been associated with HA with different degrees of severity. AAV gene transfer vectors delivering truncated and modified F8 transgenes have recently shown promising clinical efficacy in treating severe HA. However, one trial reported a decline in therapeutic efficacy over time, likely due to loss of persistence of episomal AAV vector genomes. Supraphysiologic levels of clotting in another trial led to thrombotic events. These outcomes emphasize the need to develop strategies for the stable physiologic expression of corrected genes. The permanent correction of genetic mutations by genome editing offers clear advantages over gene transfer therapy. The corrected genome is expected to provide persistent, long-lived therapeutic efficacy and regulated physiologic expression levels under the control of endogenous regulatory circuitry. AAVHSC represent a family of naturally occurring AAVs isolated from hematopoietic stem cells that mediate efficient homologous recombination-based genome editing in the absence of exogenous nucleases. We have previously demonstrated successful editing of the I22I mutation of the F8 gene using AAVHSC genome editing vectors in primary human and I22I patient-derived cells. The vector consisted of left and right homology arms flanking a codon optimized cDNA of exons 23-26. We have also demonstrated efficient and stable in vivo editing of the genomic F8 locus in mice. Here, we explore the potential of the AAVHSC platform to correct more than 90% of the remaining over 3000 mutations that are scattered throughout nearly 184 kb large F8 gene. To achieve this, we have designed three editing vectors to correct mutations located throughout the F8 gene. The N-terminal editing vector consisting of a codon optimized exon 2-13 cDNA is designed to correct all mutations in those exons. Upon successful editing, the codon optimized cDNA is designed to replace the endogenous genomic sequences spanning exons 2 to 13. The transcript from the edited F8 gene will then be spliced to the downstream exons 14 to 26 to generate a full-length mRNA encoding the wild type FVIII protein. Similarly, a central editing vector consists of a codon optimized exon 14 flanked by homology arms. Similarly, the C-terminal editing vector consists of the codon optimized cDNA of exons 15-26 flanked by homology arms. Unlike the N-terminal and the central editing vectors, the C-terminal editing vector mediates targeted insertion at the start of exon 15 and does not replace a large segment of F8 genomic DNA. Notably, this allows retention of several important genes that are encoded within the 3' end of the F8 gene. These vectors were packaged in AAVHSC15 and used to edit primary human liver sinusoidal endothelial cells, the primary producers of FVIII protein. Successful editing was observed in 10-40% of cells with the N-terminal and C-terminal editing vectors. Together these data demonstrate the feasibility of therapeutic correction of over 90% of diverse non-I22I F8 mutations associated with hemophilia A.

1438 Multi-Epitope DNA Vaccine Targeting Cancer Neoantigens Enhances Efficacy of Anti-PD1 Therapy

Pratik S. Bhojnagarwala
Wistar Institute, Philadelphia, PA

Background: Immune checkpoint inhibition (ICI) has revolutionized cancer therapy and significantly improved survival of patients across many different types of cancer. However, ICI is only effective in a subset of patients and most patients do not respond to ICI. Neoantigens are tumor specific antigens derived from somatic mutations within the cancer cells. They can also be derived from gene/RNA fusions and are recognized by the host immune system as foreign antigens. Several studies have shown that the success of ICI is linked to the number of neoantigens in the patient's tumor. Here, we demonstrate that a DNA vaccine targeting 40 neoantigens derived from MC38 mouse model of colon cancer synergizes with anti-PD1 antibody and improves the efficacy of anti-PD1 therapy. **Methods:** We performed whole exome sequencing on MC38 tumors to identify neoantigens. Based on the sequencing data, we identified 40 neoantigens based on predicted affinity to class I MHC binding. All 40 neoantigens were encoded into a single plasmid vector, each neoantigen separated by a furin cleavage site. Immune responses were measured in C57/Bl6 mice via IFN-γ ELISPOT assay and flow cytometry. Finally, we tested ability of MC38vax to control tumors *in vivo* and whether co-treatment with anti-PD1 antibody treatment improved tumor control. **Results:** Based on ELISPOT data, we observed that 11/40 neoantigens generated immune responses in mice. We also tested immune response to WT peptides and saw that the vaccine induced immune response was specifically against mutated peptides. Based on flow cytometry, we observed that the vaccine induced predominantly CD8+ T cell responses, although CD4+ T cell responses were also observed. In a

therapeutic tumor challenge, both anti-PD1 antibody and MC38vax as single treatment partially controlled the growth of MC38 tumors. However, co-treatment with both therapies demonstrated a 100% tumor control rate and significantly improved survival of tumor bearing mice. **Conclusions:** We have developed a DNA vaccine coding for 40 neoantigens that generated strong immune responses in mice. The vaccine significantly improved the efficacy of anti-PD1 antibody therapy and led to complete control of all tumors in an *in vivo* tumor challenge. Studies are ongoing to study whether the DNA vaccine can also improve the efficacy of anti-CTLA4 therapy.

1439 Immunosuppression Regimens in AAV Vector Gene Therapy Trials: A Longitudinal Review of a Cohort of Studies Conducted in the Last 5 Years

Meagan Spychala, Tanya Colhoun, Melissa Cook, Kaitlyn Huff, Andrew Graber, Timothy M. Miller

PPD, part of Thermo Fisher Scientific, Wilmington, NC

The number of gene therapy clinical trials continue to increase, with over 500 Phase 1-3 trials being conducted in 2022. Untoward immune responses have been documented in recent literature for AAV vector-based therapies, including various inflammatory toxicities resulting from complement activation, cytopenias, and heterogeneous hepatotoxicities, to name a few. It is critical to understand, predict, and proactively manage these responses to delivery greater trial and investigational therapeutic safety to the patient community. Over the past 5 years, we have witnessed a clear change in how immunosuppression regimens are employed across a wide variety of clinical studies and indications. To understand how a subset of these regimens are evolving, a review of a series of greater than 20 protocols utilizing AAV vector-based gene therapies was performed. Reviewed protocols all had at least one patient enrolled within the last five years' and varied in clinical indication and route of gene therapy administration. Comparisons of the protocol version under which the first patient was randomized were made with the current protocol version to identify changes in immunosuppression regimens. Based on this review, there has been a trend to initiate immunosuppression regimens earlier in the clinical trial course and/or to alter dosing or titration schedules. Data will provide a summary of typical immunosuppression regimens, how the landscape has changed, and medications that are being included in more recent protocol versions to address untoward side effects. Additionally, examples that describe why regimen changes were made will be provided. This review shows that providing immunosuppression therapy at the time of gene therapy administration is one important way to support patient safety in these trials.

1440 Adeno-Associated Viruses (AAV) Displaying Single Domain Antibody Against AXL for Cancer Gene Therapy

Anne-Marie Ndour[1,2], Lovro Jalsic[1,2], Viktoria Lytvyn[2], Nasha Nassoury[2], Traian Sulea[3], Maria. L Jaramillo[4], Parminder Chahal[2], Alaka Mullick[2], Bruno Gaillet[1], Rénald Gilbert[2,5]

[1]Department of Chemical Engineering, Université Laval, Quebec, QC, Canada,[2]Department of Production Platforms & Analytics, Human Health Therapeutics Research Center, National Research Council Canada, Montreal, QC, Canada,[3]Department of Immunobiology, Human Health Therapeutics Research Center, National Research Council Canada, Montreal, QC, Canada,[4]Department of Translational Bioscience, Human Health Therapeutics Research Center, National Research Council Canada, Montreal, QC, Canada,[5]Department of Bioengineering, McGill University, Montreal, QC, Canada

The use of adeno-associated viruses (AAV) as vectors for gene therapy has increased in recent years. Here, we incorporated an original single-domain antibody (sdAb) into the VP1 capsid of AAV serotype 2 (AAV2) to enable it to specifically bind to a receptor tyrosine kinase (Axl) widely expressed on many cancer cell lines, including SKOV-3 cells. The reduced size of sdAbs (~15 kDa) associated with high stability, specificity and their ability to bind with high affinity to their antigens make them promising alternatives to conventional antibodies and allow their incorporation into other proteins in viral vectors with minimal disruption of the native protein activity. In order to investigate their targeting efficacy, AAV with the modified capsid (AAV-sdAb) expressing GFP as a reporter were produced by transient transfection of HEK293SF-3F6 cells, purified by ultracentrifugation using iodixanol step-gradients and concentrated by Tangential-flow filtration using Hollow fiber membranes. To prove specificity for SKOV3 cells, plasmids required for AAV-sdAb production were mutated to inhibit the binding of AAV2 to its main receptor on the cell surface: heparan sulfate proteoglycan. Characterisation of this modified AAV-sdAb showed that the mutations led to a reduced tropism toward AAV2 natural receptor. More importantly, the viral vectors infected specifically the SKOV3 cells as a result of the inserted anti-Axl antibody. Competition experiments using heparin sulfate and the same anti-Axl sdAb that was incorporated into the AAV-sdAb, demonstrated that transduction of SKOV3 cells occurred through interaction with Axl. Therefore, this study proves that it is possible to re-target the AAV from its natural cell surface receptor to the receptor of interest by incorporating a sdAb into the capsid. Such strategy would be of great interest for cancer therapy by increasing the specificity of AAV for the delivery of toxic pay loads to cancer cells.

1441 Potent *In Vivo* CAR T Cell Generation and Durable Antitumor Activity in Preclinical Models Using VivoVec, a Surface-Engineered Lentiviral Vector Drug Product

Chris Nicolai[1], Jim Qin[1], Melissa Thill[2], Weiliang Tang[1], Alyssa Sheih[1], Alessandra Sullivan[1], Susana Hernandez[1], Don Parilla[1], Lisa Song[1], Way Wu[1], Mollie McDonnell[1], Erica Shirazi[1], Greyson Hamilton[1], Seungjin Shin[1], Andrew Scharenberg[1], Wai-Hang Leung[1], David Peritt[2], Ryan Larson[1], Byoung Ryu[1], Laurie Beitz[1]

[1]Umoja Biopharma, Seattle, WA,[2]Lupagen, Northbrook, IL

Autologous chimeric antigen receptor (CAR) T cell therapies have revolutionized the treatment of B cell malignancies, leading to long-term remission in a substantial number of patients. Despite the promising clinical efficacy of CAR T cells in hematologic malignancies, major limitations hinder their widespread application, including challenges for patient access, complex manufacturing, and high cost. To overcome these challenges, Umoja has developed VivoVec, a novel off-the-shelf surface-engineered lentiviral vector platform for *in vivo* CAR T cell generation. To achieve specific and efficient *in vivo* T cell transduction, VivoVec particles are surface-engineered with the cocal fusion glycoprotein and incorporate an anti-CD3 single chain variable fragment (scFv) and T cell costimulatory ligands on the particle surface to promote T cell binding, activation, and transduction. Here we demonstrate that CAR T cells generated with VivoVec particles exhibited a less-differentiated, central memory-like phenotype and enhanced CAR-antigen-specific polyfunctionality, including cytokine production, proliferation, and tumor cell killing *in vitro*. VivoVec particles have high selectivity and avidity for T cell binding. This enables efficient *in vivo* CAR T cell generation through multiple routes of administration, including direct injection or delivery via an extracorporeal gene delivery (ECGD) system. The ECGD system combines a standard leukapheresis collection followed by selective binding of VivoVec particles to T cells in a single closed-loop bedside procedure. The system has a binding chamber which enables consistent and controlled interaction between VivoVec particles and T cells. The binding properties afforded by the VivoVec surface engineering enable selective binding to T cells in the ECGD system in less than 1 hour, followed by an in-line wash to remove any unbound particles. The particle-bound T cells are then infused into the patient as part of the vein-to-vein bedside system. In a humanized NSG mouse model of B cell malignancy we observed that VivoVec particles generated substantial numbers of CAR T cells in the blood, resulting in potent and durable antitumor activity at low doses following direct *in vivo* administration or via the ECGD system. CAR T cell generation *in vivo* and CAR T cell mediated antitumor responses were enhanced by VivoVec particles surface engineered with T cell costimulatory molecules, as demonstrated by 20-50-fold higher numbers of CAR T cells in the circulation and greater antitumor responses at lower VivoVec doses compared to lentiviral particles lacking T cell costimulatory molecules. Our results demonstrate that incorporation of costimulatory molecules onto the surface of VivoVec particles promotes selective T cell binding, activation and transduction, resulting in the generation of potent polyfunctional CAR T cells *in vivo* that can rapidly clear primary a tumor and provide protection against tumor re-challenge. Overall, these data demonstrate that our surface-engineered VivoVec particles efficiently generate highly functional CAR T cells *in vivo*, following either direct injection or via the ECGD system . VivoVec particles have the potential to overcome many of the limitations associated with the current class of CAR T cell therapies.

1442 A Novel CRISPR-Cas9 Strategy to Target Dystrophin Mutations Downstream of Exon 44 in DMD Patient-Specific iPS Cells

Neha R. Dhoke, Hyunkee Kim, Karim Azzag, Rita Perlingeiro

Lillehei Heart Institute, Department of Medicine , University of Minnesota, Minneapolis, MN

Duchenne Muscular Dystrophy (DMD), one of the most common forms of muscular dystrophy, is caused by mutations in the dystrophin gene. Although there are several approaches in the pipeline for clinical translation, there is still no effective treatment for DMD. An attractive approach is autologous cell transplantation utilizing human pluripotent stem (PS) cell-derived myogenic progenitors. Since rescue of full-length dystrophin is very challenging due to size constraints, here we leveraged the fact that a significant number of deletion mutations occur in the region between exons 45 and 55, known as the hotspot, and developed a gene knock-in approach to genetically correct any mutations downstream of exon 44. Our strategy consists of knocking-in the cDNA of exon 44 connected to exons 58-70. This introduces a miniature version of dystrophin protein (mini-DYS), which maintains the reading frame and the cysteine-rich domain that is essential for β-dystroglycan binding. We applied this approach to two DMD patient-specific iPS cell lines, GM25313 and cDMD012499-9, carrying mutations in exon 45 and 51, respectively, by integrating the short DMD cDNA via homology directed repair using CRISPR/Cas9-mediated double-strand break near the 5' end of exon 44. Knock-in was confirmed by PCR. Using conditional expression of PAX7, we differentiated gene corrected GM25313 and cDMD012499-9 iPS cell lines (2 clones each) and uncorrected counterparts into PAX7+ myogenic progenitors, and subsequently into to myotubes expressing myosin-heavy chain. Western blot and immunofluorescence staining confirmed mini-DYS expression at the protein level in the gene edited DMD iPS cell lines, but not in uncorrected counterparts. Spontaneous activity led to release of creatinine kinase (CK) into the medium, detected at lower levels in corrected DMD cultures. Transplantation of gene corrected DMD myogenic progenitors into NSG/mdx mice produced human donor-derived myofibers expressing both human-specific DYS and LAMIN A/C, suggesting *in vivo* rescue of dystrophin expression. These findings provide further proof-of-principle for the development of autologous iPS cell-based cell therapy for genetic disorders using programmable nucleases

1443 Enhancement of Newcastle Disease Virus AMHA1 Strain Oncolytic Activity through Inhibition of Heat Shock Protein 70 in Colorectal Cancer Cells. Clinical and Experimental Study

Ahmed M. Al-Shammari[1], Farah E. Ismaeel[2], Ali Z. Al-Saffar[3], Marwa I. Salman[4]

[1]Experimental Therapy, Iraqi Center for Cancer and Genetic Research, Mustansiriyah University, Baghdad, Iraq,[2]Human Anatomy, College of Medicine, Mustansiriyah University, Baghdad, Iraq,[3]College of Biotechnology, University of Al-Nahrain, Baghdad, Iraq,[4]Biotechnology, College of Science, University of Baghdad, Baghdad, Iraq

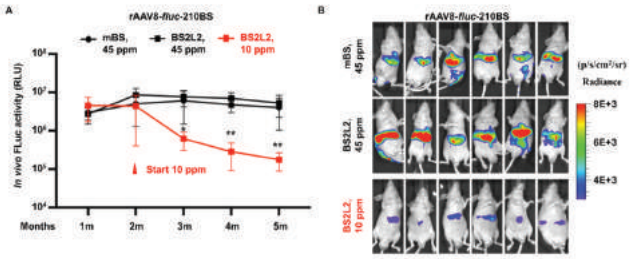
The most frequent gastrointestinal cancer is colorectal cancer (CRC), which is a considerable global health concern. The colorectal cancer cells are stressed cells that express large quantities of intracellular and extracellular heat shock protein 70 (Hsp70) to correct distorted proteins, prevent cellular senescence, interfere with tumor immunity, enhance angiogenesis, and help metastatic formation by increasing resistance to treatment. They also secrete Hsp70 outside the cell, affecting immune cells directly and increasing cytokines production. Therefore, Hsp70 inhibition as a targeted therapy becomes a necessity. The current work aimed to Investigate the increased expression levels of Hsp70 in colorectal cancer patients' serum and cancer tissues and its possible targeting for cancer therapy. We targeted colorectal cancer cells by combining Hsp70 inhibitor KNK437 with NDV AMHA1 Iraqi strain to prevent cancer cells from reducing the stress initiated by NDV. **Methods**: The clinical study was conducted on 94 individuals divided into two groups. Group I: 54 patients diagnosed with colorectal cancer, and Group II: 40 patients diagnosed with different colorectal diseases with no malignancy. We collected serum and tissue to investigate the Hsp70 level of expression. Moreover, we checked IL-1 and IL-10 cytokine levels in serum samples of CRC patients to highlight this pathway's importance in patients' immune status, which may affect CRC progression that has a strong relationship with hsp70 pathways. In vitro study utilized a colorectal cancer cell line, HRT-18G as a model to study the inhibition of Hsp70 and the cytotoxicity of Newcastle disease virus (NDV) as an oncolytic virus. Hsp70 expression was checked in the HRT-18G, which was found to be elevated. **Results**; An immunohistochemical (IHC) study showed that Hsp70 was positively detected in all colorectal cancer tissue samples with significant ($p < 0.0001$) intracellular expression compared with non-malignant, healthy tissue samples. Extracellularly, the serum levels of Hsp70 and IL-1, and IL-10 were significantly ($p < 0.0001$) elevated in CRC samples compared with the control. To translate the clinical finding into experimental targeted therapy as proof of concept, we targeted Hsp70 using KNK437, which induces significant inhibition of Hsp70 in CRC cells *in vitro*. Cancer cells exposed to NDV showed a substantial killing effect compared to untreated cells. The combination therapy of NDV and KNK437 (Hsp70 inhibitor) showed synergism in reducing the viability of CRC cells with a neglectable effect on normal cells when analyzed using the Chua-Talalay equation. Hsp70 expression levels in CRC cells were investigated using qPCR, IHC, and ELISA after monotherapy and combination therapy. The expression of Hsp70 was suppressed by KNK437 and NDV-KNK437 combination therapy but elevated when the CRC cells were infected with NDV. These findings suggest that combination therapy kills through increasing stress on cancer cells by suppressing Hsp70, resulting in higher cytotoxicity against cancer cells. Acridine orange/propidium iodide double staining confirmed the ability of combination therapy to induce apoptosis in colorectal cancer cells at a higher level than applying individual therapies. In conclusion, oncolytic NDV AMHA1-KNK437 combination therapy enhanced the antitumor activity against colorectal cancer cells and demonstrated strong synergy that suggests a novel anti-colorectal cancer treatment that can be applied clinically.

1444 Conditional Regulation of rAAV-Delivered Hepatic Therapeutics by Iron and miRNA-210-3p

Ming Yang, Yun He, Heng Bin Yang, Li Ping Zhou, Si Yuan Wang, Chen Ling, Qing Yun Zheng

Fudan University, Shanghai, China

Liver gene therapy based on recombinant adeno-associated virus (rAAV) vector has achieved great success, but the regulation of transgene expression has remained a problem. It has been reported that incorporating tissue-specific miRNA binding sites into rAAV expression cassettes could de-target transgenes from specific cell types. Iron, one of the most extensively studied nutrients, is recycled and stored mainly in the liver with a wide normal range. To date, the crosstalk between miRNA and iron homeostasis, especially within the normal range, is not clear. In the current study, we aimed to take advantage of a hepatic miRNA that is specifically regulated by iron at physiological levels, in order to achieve control of rAAV-mediated transgene expression in the liver.Here, we reported that the expression of miR-210-3p, whose baseline level is low in the liver, was dramatically upregulated by diet iron in both normal and immune-deficient mice. Though miR-210-3p is not liver-specific, we observed that miR-210-3p was up-regulated most significantly in the mouse liver (17.6-fold).We further explored the underlying molecular mechanism. We found that the methylation status of the promoter region of miR-210-3p (m210p) was significantly changed after iron chelator treatment. When m210p was cloned to a GLuc plasmid and transfected into Hepa1-6 cells, *gluc* expression could be enhanced by iron chelator. When we mutated the hypoxia-inducible transcription factors (HIF) 1α binding sites in the m210p, iron chelator could no longer enhance the *gluc* expression. Given that DNA methylation is central to binding of HIF on promoter regions and that HIF pathway is well known to control iron-related gene expression, it was evident that HIF1α binding sites in the miR-210-3p promoter are essential for iron-mediated upregulation of miR-210-3p.Finally, we showed that the hepatic transgene expression from miR-210-3p binding site-incorporated rAAV vectors could be significantly regulated by iron-chelator *in vitro* and diet iron *in vivo* (Fig.1). Most importantly, we showed that the regulation could be applied to not only reporter genes, but also a CRISPR-effector gene.In summary, we identified miR-210-3p that significantly response to iron status in the liver, revealed its molecular mechanism, and exploited it to achieve control of rAAV-mediated transgene expression in the liver. Considering the simple oral route and the comprehensive safety profile of diet iron, our studies provide a unique opportunity to improve the safety and efficacy of liver-targeted gene therapies.



1445 Development of High Yield Plasmid and mRNA Manufacturing Process in Scalable Level

Yong Wu, Zihao Fang, Yijun Shen, Houliang Wei, Qingrui You, Guodong Jia, Weiran Shen

OBiO Technology (Shanghai) Corp., Ltd, Shanghai, China

In recent years, mRNA technology has been widely used in treating infectious diseases, cancer, and rare diseases due to its remarkable platform technology advantages. The safety and efficacy of mRNA therapeutics have been demonstrated in COVID-19 vaccines. Process development is a critical step during the development of mRNA therapeutics, which includes plasmid and template preparation, in vitro transcription (IVT) reaction and mRNA purification. In this study, our team has developed a process development platform for plasmid and mRNA manufacturing with optimized critical process parameters (CPP) of the main steps. By optimizing the concentration of NaOH in alkali lysis buffer, the yield of plasmid was increased by 36%. By optimizing the concentration of calcium chloride added into neutralized lysate, the residual host cell RNA (HCR) levels in neutralized lysate were significantly reduced. After UF/DF, crude plasmid samples were purified by gel filtration chromatography, the residual host cell protein (HCP) and HCR were reduced to 0.1 μg/mg plasmid by ELISA and qPCR analysis. After further purification by hydrophobic chromatography, the host cell DNA (HCD) residue was controlled within 2 μg/mg plasmid. The open-loop plasmid and linearized plasmid impurity was controlled less than 2% with the supercoiled plasmid over 95%. In linearization stage, by optimization of plasmid concentration, enzyme concentration, reaction time and other parameters, the purity of the linearized plasmid was more than 97% by AEX-HPLC analysis. AGE analysis of linearized plasmid showed a clear single band. In IVT reaction processing, the optimization lies in the source and concentration of T7 polymerase, the concentration of the linearized template, NTP material, cap analogues, and the reaction time. The mRNA concentration and purity reached 12 mg/mL and more than 90% when IVT reaction is processed under optimized conditions. In the final product, the dsDNA content was found less than 0.5% and the purity of mRNA more than 95% after Oligo dT affinity chromatography purification. The optimized IVT and purification process of have been verified at the scale of 3,000 mg mRNA drug substance. In summary, OBiO's process development platform demonstrated high yield, high purity mRNA manufacturing capabilities by optimizing CPPs mentioned above.

1446 Development of *In Vitro* Neuronal Cytotoxicity Models for Neurodegenerative Disease Gene Therapy R&D

Ann Lettko, Josefa M. Sullivan, Jeroen Bastiaans, Benjamin Campbell, Barbara Nguyen-Vu, Matthew J. During, Alexandria Forbes, Ce Feng Liu

Molecular & Protein Engineering, MeiraGTx LLC, New York, NY

Globally, neurological disorders such as Alzheimer's Disease, Parkinson's Disease, Amyotrophic Lateral Sclerosis (ALS), and Frontal Temporal Dementia (FTD) are the second leading cause of death, with millions of new diagnoses each year. ALS alone affects 1 in 50,000 people per year worldwide, calling for increased demand in efficient therapies. Cytoplasmic mislocalization and the subsequent accumulation and aggregation of transactive response DNA-binding protein 43 kDa (TDP-43) is a hallmark of ALS and, in most cases, represents a reliable post-mortem diagnostic marker. Multiple studies have demonstrated that overexpression of TDP-43 in animal models results in neurodegeneration and can be used as a disease model for ALS and other neurological disorders involving TDP-43. While valuable, *in vivo* TDP-43 disease models are hindered by their low throughput capabilities. Here, we propose two cellular models of TDP-43 induced cytotoxicity mediated by adeno-associated virus (AAV) transduction. First, primary cortical mouse neurons were transduced with AAV containing TDP-43 and cytotoxicity was tracked over time. Dose-dependent cytotoxicity, as well as changes in morphology, were observed in the TDP-43-transduced neurons. The same experiment was conducted using ReNcells, an immortalized human neural progenitor cell line. Like for primary cortical mouse neurons, treating ReNcells with AAV-TDP-43 resulted in dose-dependent cytotoxicity determined by LDH activity and AO/PI staining. Our data demonstrate that these *in vitro* models have the potential to be used in high throughput screens and functional potency assays for neuroprotective gene therapies development.

1447 Non-Evolved dCas9 Epigenetic Editors Targeting NGG PAM Sites Are Required for Knockdown of *HTT*

Jennifer Waldo[1], Julian Halmai[1], Jasmine L. Carter[1], Drew Brown[1], Jan A. Nolta[2], Kyle Fink[1]

[1]Ctr. for Interventional Genetics, MIND Institute, Department of Neurology, UC Davis, Sacramento, CA,[2]Stem Cell Program, Gene Therapy Center, Institute for Regenerative Cures, UC Davis, Sacramento, CA

Huntington's Disease (HD) is a fatal, autosomal dominant neurodegenerative disorder caused by a trinucleotide repeat in exon 1 of the Huntingtin (*HTT*) gene. This expansion leads to protein misfolding that causes widespread cellular dysfunction and ultimately leads to cell death. There are currently few treatments and no cures, with death occurring 10-15 years after disease onset. The advent of CRISPR-dCas9 technologies allows for the targeting of the causative gene and subsequent downregulation via fused effector domains that elicit an effect at the epigenetic level to induce heterochromatin and block transcription. Allele specificity is important in HD, as HTT has essential functions within the cell and total knockdown could be deleterious. HD has large haplotype blocks that allow for allele-specific targeting based upon the presence of heterozygous single nucleotide

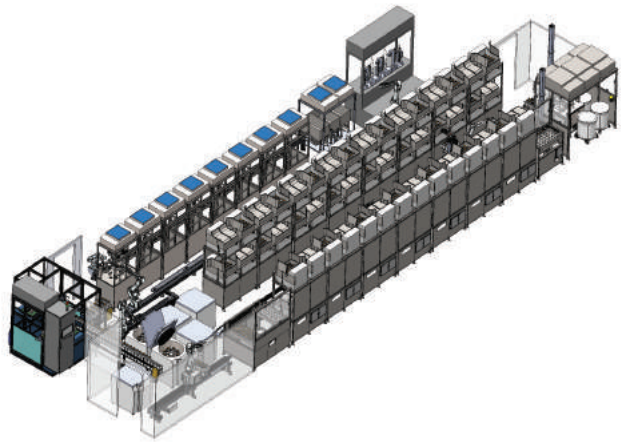
polymorphisms (SNPs). These SNPs are in genomic regions devoid of NGG PAM sites, a requirement for SpdCas9 binding. To address this bottleneck, we conducted a screen of multiple dCas9 variants fused to KRAB and DNMT3A/L with increasingly expanded PAM targeting to assess the ability to downregulate *HTT* and provide allele specificity. Surprisingly, only SpdCas9 was able to significantly knockdown *HTT*, while expanded PAM site variants dxCas9 and dCas9-VQR were unable to reduce *HTT* expression. Locus occupancy analysis by ChIP-qPCR was performed to identify differential binding enrichment of dCas9 variants. We further investigated these effects by quantifying epigenetic changes at the promoter through bisulfite sequencing for DNA methylation and ChIP-qPCR for H3K9me3. We then assessed knockdown in neuronal stem cells from an HD patient and healthy controls. We measured knockdown efficiency in our healthy controls and HD patient cells by qPCR. In addition, we have shown the ability to package this dCas9 system into a viral-like particles (VLP) and show subsequent delivery and knockdown of *HTT in vitro*. Such VLP strategies have shown growing promise through co-opting the viral packaging system to direct packaging of ribonucleoprotein complexes. In conclusion, this platform can be modified for application in multiple neurologic diseases that will allow for the target and treatment of previously untreatable disorders that were limited by a dominant negative etiology.

1448 Engineering an Automated Platform for High-Throughput Production of Plasmid DNA for Cell and Gene Therapy

Chamath Chandrasekera, Steven Hughes

Genscript, Piscataway, NJ

The global demand for plasmid DNA has increased rapidly since the advent of cell and gene therapies (CGT) followed by hyper-growth during the outbreak of the COVID-19 pandemic. These cutting-edge therapies come in many forms but all of them rely on plasmid DNA at some point either in their manufacture or mechanism of action. Unfortunately, scaling up manufacturing capacity for plasmid DNA is a difficult operation and it has become a bottleneck for the CGT industry. Most companies outsource plasmid production to partners such as contract development and manufacturing companies (CDMOs) who are specialists in the arena and have in-house manufacturing platforms. CDMOs can no longer meet the demand for high quality plasmid DNA due to substantial backlogs and the lack of automated solutions for plasmid manufacturing. This can significantly impede R&D efforts and increase time-to-market delaying access for patients to these potentially curative therapies. Here we present GenScript's new high-throughput plasmid production platform designed to produce up to 1000 ultra-low endotoxin plasmids at the mg scale per day. This is an integrated platform bringing the best of industrial automation to a biological manufacturing process. The platform consists of six robot operated modules encompassing inoculation, incubation, lysis, chromatography and solvent extraction. It can operate continuously in a 24 hour cycle with in-process cleaning to prevent cross-contamination (Figure 1). All sample handling will be under HEPA-filtered enclosures to prevent contamination. We also present a new paradigm for bacterial culture and lysis in single-use bottles instead of flasks or fermenters. We have demonstrated that we can obtain yields of >0.7mg for both low and high-copy plasmids with endotoxin levels < 0.05EU/μg and supercoiled content >80% (Figure 2). Our platform can produce transfection grade plasmid libraries for AAV capsid libraries, antibody libraries, CRISPR libraries and *in vitro* transcription (IVT) templates for mRNA production for the CGT industry. GenScript will accelerate the commercialization of new CGT products by providing high quality plasmids with a two day turnaround time.



1449 The Therapeutic Effects of Antisense Oligonucleotides in iPSC-Derived Neurons of Patients with LBSL

Manouchehr Amanat, Shiqi Guang, Amena Fine, Ali Fatemi, Christina L. Nemeth

Neuroscience and Neurogenetics, Kennedy Krieger Institute, Baltimore, MD

Background: Leukoencephalopathy with brainstem and spinal cord involvement and lactate elevation (LBSL) is an ultra-rare inherited mitochondrial disorder characterized by progressive spastic gait, ataxia, and posterior spinal cord involvement. LBSL is caused by mutations in *DARS2*, which disrupt the mitochondrial aspartyl-tRNA Synthetase. Compound heterozygote mutations consisting of one mutation in intron 2, affecting splicing of exon 3, and one missense mutation have been found in over 90% of the identified cases with LBSL. It is postulated that restoring *DARS2* mRNA expression by increasing exon 3 inclusion may improve protein function and result in a positive clinical outcome. We therefore aimed to design an antisense oligonucleotide (ASO) targeting *DARS2* mRNA in an attempt to enhance exon 3 inclusion and restore gene expression (Figure 1). **Methods:** Fifteen ASOs were designed to target possible intronic splicing silencers upstream of exon 3. The ASOs were 20 base pairs in length. All nucleotides included 2′-O-methoxyethyl (2′-O-MOE) and phosphorothioate (PS) modifications to enhance ASO stability and prevent RNase-H activity. Induced pluripotent stem cells (iPSCs) were derived from blood cells of three LBSL patients and one healthy control. iPSCs were transfected by ASOs to find the most effective ASO in increasing exon 3 inclusion by RT-qPCR. The ASO with the highest inclusion efficacy was tested in two doses (50nM and 100nM) on iPSC differentiated neural progenitor cells (NPCs). In addition to RT-qPCR for inclusion/exclusion of exon 3, lactate was assessed (Lactate Reagent Set, Pointe Scientific) on the cultured media of iPSC differentiated motor neurons to evaluate mitochondrial function. **Results:** The ASO targeting 180 to 200 nucleotides upstream of *DARS2* exon 3 revealed the

highest elevation in exon 3 inclusion, compared to the other designed ASOs and untreated iPSCs. RT-qPCR of NPCs transfected by this ASO showed increased levels of *DARS2* mRNA including exon 3 and reduced levels of *DARS2* mRNA excluding exon 3 in three LBSL cell lines in a dose dependent manner. Furthermore, 30-day motor neurons treated with ASO for one week demonstrated lower levels of lactate, compared to the baseline lactate levels of LBSL neurons. Reductions in lactate levels were observed in a dose dependent manner. **Conclusions:** ASO therapy shows promise to restore gene expression in iPSC derived NPCs of patients with LBSL. The role of ASO in modulating lactate levels in LBSL neurons suggests improvements in mitochondrial function.

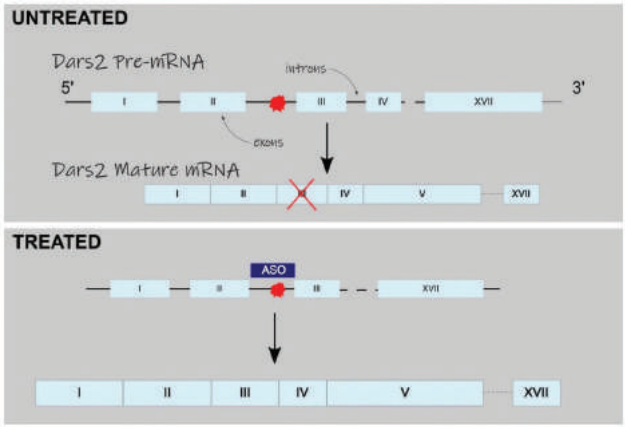


Figure 1. Most patients with LBSL have reduced exon 3 expression within *DARS2* mRNA due to a splice site mutation in intron 2. Antisense oligonucleotides (ASOs) targeting intronic splicing silencers upstream of exon 3 may restore gene expression.

1450 3D Bioprinted Liver Tissues Rescue a Murine Model of CCl_4- Induced Acute Liver Failure

Christopher TD Dickman, Zainab A. Bazzi, Oksana Nemirovsky, Farin V. Livary, Fiona Li, Stephanie Campbell, Haley H. L. Tong, Reza Jalili, Sam Wadsworth, Spiro Getsios, Rafal P. Witek

Aspect Biosystems, Vancouver, BC, Canada

Background: The standard of care treatment for Acute Liver Failure (ALF) and Acute Chronic Liver Failure (ACLF) is liver transplantation. However, due to the limited supply of suitable donor organs, a high proportion of patients with liver failure die while waiting for a liver transplant. The transplantation of isolated primary hepatocytes is a promising treatment for pediatric patients with ALF; however, implementation and scaling of this treatment remains a challenge. In this study, we demonstrate that xenogeneic 3D bioprinted liver tissue therapeutics, containing primary human hepatocytes (PHHs), and mesenchymal stromal cells (MSCs), are capable of rescuing immunocompetent mice from Carbon tetrachloride (CCl_4)-induced ALF when implanted into either the IP or SubQ space, without the need for immunosuppression. **Methods:** Prior to printing, PHHs and MSCs were formed into spheroids and then suspended in an alginate-based biomaterial. Liver tissues containing 5 million hepatocytes and 5 million MSCs were manufactured using Aspect Biosystems' microfluidic 3D bioprinter. For the study, immunocompetent C57BL/6 mice were injected with titrated CCl_4 to induce liver failure. After 1 day, the mice were implanted with 2 liver tissues into either the IP or SubQ space. Control mice treated with CCl_4 were implanted with cell-free bioprinted tissues. For analysis, blood was collected at -7, 1, and 7 days post-surgery to measure endogenous liver damage using alanine transaminase (ALT) levels, and implanted liver tissue function via human albumin levels. Animals were euthanized at the end of the experiment and the liver was collected for histological examination. **Result:** Implantation of bioprinted liver tissues containing human cells significantly improved survival in mice with CCl_4-induced liver failure. CCl_4-treated mice that received liver tissues into the IP space had a survival rate of 78% vs 47% for control CCl_4-treated mice. Mice that received liver tissues in the SubQ space demonstrated equivalent efficacy, with a survival rate of 85% vs 50% for control mice. This experiment was repeated with hepatocytes from an alternate donor. Upon replication, the survival rate for treated mice was 50% vs 13% for cell-free implanted mice. Across all three experiments, the survival rate for CCl_4-treated mice was 68% for animals that received PHH/MSC tissues vs 35% for mice receiving cell-free control tissues. The p-value was 0.003. ALT levels peaked on day 1 post-surgery at over 1000 U/L. Liver histology of mice that succumbed to liver failure before day 7 showed extensive liver necrosis. Treated and untreated mice surviving until the end of the experiment showed significant evidence of liver regeneration and normal liver parenchyma restoration. **Conclusion:** Our data demonstrates that 3D bioprinted liver tissues implanted IP or SubQ significantly reduced mortality of immunocompetent mice from CCl_4-induced ALF. As such, 3D bioprinted tissue therapeutics have the potential to act as a bridge to recovery or transplantation for individuals with ALF or ACLF. Our results also suggest that 3D bioprinted hepatocytes could be applicable in the treatment of other chronic metabolic liver diseases caused by a functional deficiency in hepatocytes. Our next steps are scaling the therapeutic to larger cell doses to examine efficacy in a rat model of ALF and a mouse model of chronic metabolic liver disease.

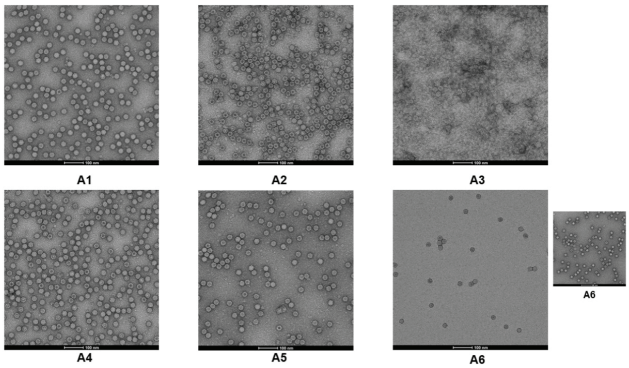
1451 Characterization of rAAV8 Vectors from Six Chinese CRO Companies

Cheng Hui Yu, Ming Yang, Ke Ying Yang, Xi Lin Feng, Chen Ling

Fudan University, Shanghai, China

Recombinant adeno-associated virus (rAAV) has drawn substantial attention as a highly promising vector for human gene therapy worldwide. rAAV vectors currently become an increasingly popular delivery tool in preclinical and clinical applications. However, it is evident that the current rAAV vector production especially in China will require improvements in quality before it can be used in clinical since its systematic production process did not begin until 2016. In this report, we characterized the quality of rAAV8 vectors produced by six Chinese CRO companies, called A1, A2, A3, A4, A5 and A6 respectively. First, genome titer, capsid titer, full capsid ratio and rAAV serotype identity were simultaneously determined through traditional methods and Stunner/Uncle machine. Although the quality data of six rAAV8 vectors under the detection of two methods were slightly different, the main trend was consistent, except for A4, in which there was too much iodixanol impacting machine detection.In terms of genome titer, A1 and A4 were the highest, A3 and A6 were the lowest,

while the A2 genome titer obtained from machine was overestimated due to excess cell-free DNA. Next, in the detection of capsid titer, A1 and A2 were the first level, and A6 was the lowest, the largest difference spanned 10 times. As for the full capsid ratio detection, the results gained from qPCR combined with Elisa showed that A6 was the highest, while A2 and A3 were the lowest. Due to the data processing method, the full capsid ratio determined by machine was meaningless. The transmission electron microscope (TEM) results showed that A1 was the highest, followed by the A4, A5 and A6 (Fig. 1). Owing to too many impurities, A3 could not be analyzed, which was also reflected in the follow-up staining. A3 was too impure to be detected for rAAV serotype identity, while the other samples all identified as the same serotype. Western blot showed that all the rAAV capsids were intact, but A3 was too impure to be detected by coomassie blue staining and silver staining. The concentration of A6 was so low that the band was too faint.Furthermore, transducing unit was analyzed, demonstrating that A1 was the highest, and A6 was the lowest. The value of transducing unit divided by genomic titer represents rAAV potency, where A1 to A4 were similar, while A5 and A6 were lower than the first four about 10 times. Finally, we detected the neutralizing antibody (Nab) titer activated by six rAAV vectors. Surprisingly, the Nab titer activated by A1 was comparable to that of A3. The other three except for A6 were all low, since A6 was insufficient to inject mice due to its low concentration.Taken together, A1 was of the highest quality, but still resulted in higher Nab titer. We are the first to systematically compare the quality of purified rAAV vectors produced by Chinese CRO companies, presenting the fact that they each have own strengths and weaknesses, providing convenience for the better application of rAAV vectors in the Chinese scientific research community.



1452 Biodistribution of LV-TSTA Transduced Rat Adipose Derived Stem Cells Used for "*Ex Vivo*" Regional Gene Therapy for Bone Repair

Mina Ayad[1], Jennifer Bell[1], Cory Mayfield[1], Elizabeth Lechtholz-Zey[1], Osamu Sugiyama[1], Amy Tang[1], Shefali Chopra[1], Daniel Oakes[1], Jay R. Lieberman[2]

[1]Department of Orthopedic Surgery, University of Southern California, Los Angeles, CA,[2]University of Southern California, Los Angeles, CA

INTRODUCTION: Massive bone loss remains a difficult clinical entity. As ex vivo and in vivo gene therapy are explored as potential treatment methods for critical sized bone defects, an assessment of their safety becomes important. Previously, we investigated the safety of lentiviral transduction of bone marrow-derived mesenchymal stem cells (BMSCs) to overexpress bone morphogenetic protein 2 (BMP-2), and found that lentiviral copy numbers declined at the defect site and were not consistently found in various internal organs at subsequent points. Subsequently, we observed greater growth potential and BMP-2 production for adipose derived stem cells (ASC) compared to BMSCs. In this study, we sought to characterize the biodistribution of viral particles at the defect site and various internal organs after implantation of ASCs transduced via lentivirus to overexpress BMP-2. METHODS: Under IRB approval, adipose cells were harvested from the infrapatellar fat pad of donors. ASCs were then isolated and cultured. Two-step transcriptional activation (TSTA) was utilized to create vectors containing bone morphogenic protein (LV-TSTA-BMP-2) and green fluorescence protein (LV-TSTA-GFP). 5 experimental groups were created, including: High-dose (HD) LV-BMP-2, standard dose (SD) LV-BMP-2, HD-LV-GFP, SD-LV-GFP and non-transduced. Utilizing a critical sized femoral defect model, cells were implanted into 12-week old athymic nude rats. Timepoints examined included 4, 14, 21, 56 and 84 days. Outcomes examined included viral copy number and histologic examination of the implant site and internal organs, liver function tests, and integration site analysis. Organ histopathologic analysis was performed by a clinical pathologist. Statistical analysis was performed using STATA17 with Wilcoxon signed-rank test or ANOVA for continuous variables and a chi-squared analysis for categorical variables. Statistical significance was set at $p<0.05$. RESULTS SECTION: Viral copy number at the defect site remained present through three weeks in both the high dose LV-TSTA-BMP-2 and standard-dose LV-TSTA-BMP-2 groups (Figure 1). Across the time points, there was a significant decrease in viral copy number at the fracture site in the cohorts ($p<0.0001$). On histologic examination, none of the samples across all time points and organs examined were noted to be abnormal. Furthermore, there was no significant number of viral copies or human cells detected in the various organs (brain, lung, heart, GI tract, liver, spleen, kidney, testis, bone marrow and blood) between 2 and 12 weeks for either the high dose or standard dose groups. Integration site analysis performed for 3 samples did not yield significant clonal abnormalities or integration sites near genes of interest. DISCUSSION/CONCLUSION: In this study, we demonstrate that LV-TSTA-BMP-2 transduced cells remain at the femoral defect site for 3 weeks before significantly diminishing in numbers. Our histopathologic data suggests that this method appears to be safe with no instances of abnormal histology noted. Furthermore, there was no significant detection of viral copies outside of the femoral defect site after 4 days in the high-dose and standard-dose LV-TSTA-BMP-2 cohorts.. Together, these data suggest that transduced ASCs remain a viable option for ex-vivo gene therapy.

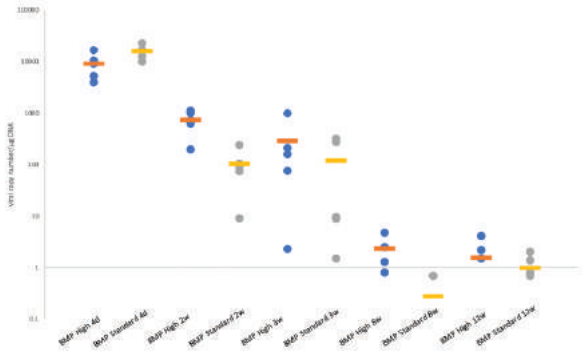


Fig 1. Viral copies per µg DNA detected in defect site by experimental group and time point.

1453 Development of an *Ex Vivo* Gene Engineered B Cell Medicine Platform with Precision, Modularity, and Broad Therapeutic Utility

Hanlan Liu[1], Tim Mullen[1], Swati Singh[2], Jasmine Edelstein[1], Carolline Bullock[1], Sean Keegan[2], Sarah Leach[1], Troy Patterson[1], Kate Molloy[1], Amy Lundberg[1], Michael Leiken[2], Ishara Datta[1], Wayne Bainter[1], Claudia Fiorini[2], Sean Arlauckas[2], Anja F. Hohmann[2], Adam Lazorchak[2], Richard A. Morgan[2]

[1]Be Bio, Cambridge, MA,[2]Be BioPharma, Cambridge, MA

Ex vivo gene and cell therapies have produced transformative medicines to treat previously intractable diseases. Still, there are barriers to the broad adoption of these efficacious therapies as current platforms lack high biosynthetic capacity, durability, and cannot be administered as an off-the-shelf medicine without conditioning. Terminally differentiated human plasma cells derived from genetically engineered B cells (termed B Cell Medicines, BeCMs), offer natural longevity (mean half-life of 17 years), capacity for high levels of protein secretion (up to 10,000 Ig molecules/cell/sec), and naturally allogenic properties, which make them an attractive platform for the sustained supply of biologics, where continuous dosing is required to achieve therapeutic benefit. Herein we describe a modular and scalable platform for the generation of BeCMs capable of stable expression and continuous secretion of biologically active therapeutic cargos. BeCMs are produced via CRISPR-based HDR-mediated transgene insertion followed by ex vivo differentiation into long-lived plasma cells. A BeCM prototype engineered to express firefly luciferase was produced and differentiated into antibody secreting cells (ASC) with a phenotype of >90% CD27+CD38+ cells. The BeCM prototype was injected via IV into immunodeficient mice, with rapid (< 3 days) bone-marrow-homing and durable engraftment (>100 days) . To illustrate the modularity of the BeCM platform we engineered B cells to produce the lysosomal storage disease (LSD) enzyme acid sphingomyelinase (ASM), clotting factor IX (FIX), and an anti-CD19/CD3 bispecific T cell engager (BiTE). ASM deficiency caused by lack of SMPD1 gene expression leads to Niemann-Pick Disease (NPD), an autosomal recessive LSD that causes sphingomyelin accumulation in organs leading to organ failure and neurodegenerative damage. BeCMs harboring an optimized SMPD1 expression cassette inserted into the CCR5 safe harbor locus was demonstrated to stably secrete ASM. HAP1 knockout cells exposed to supernatant from SMPD1-engineered BeCMs showed restored ASM activity, and reduced accumulation of pathological sphingomyelin as demonstrated by liquid chromatography-mass spectrometry. Hemophilia B is an X-linked coagulation disorder caused by deficiency of functional FIX protein (FIX). Insertion of a FIX transgene construct at the CCR5 locus and subsequent differentiation into ASCs, resulted in FIX production with biological activity as measured by a chromogenic enzyme activity assay and activated partial thromboplastin time assay. FIX-expressing BeCM were transferred into immunodeficient mice, with FIX production demonstrated >12 weeks in vivo. As a third example, we engineered B cells to produce an anti-CD19/CD3 BiTE mimicking the drug Blincyto®, an approved continually-dosed therapy for relapsed/refractory Acute Lymphoblastic Leukemia (ALL). Supernatant from BiTE-producing BeCMs directed primary human T cells to kill Raji tumor cells (CD19+), demonstrating potent in vitro anti-tumor activity. In summary, we demonstrated the ability to transform the power of B cells into a platform for the advancement of B cell-based medicines. Successful production of highly divergent biologics such as LSD enzymes, serum proteases, and anti-tumor bispecific engagers highlight the therapeutic versatility and modularity of our BeCM platform. BeCMs capable of expressing one or more therapeutically relevant transgenes have the potential for broad and meaningful therapeutic utility in rare diseases, cancer, and beyond.

1454 Human Anti-SARS-CoV-2 Tetravalent Bispecific Antibody Broadly Neutralizes Major Variants of Concern Including Omicron Sub-Variants

Abhishek Chiyyeadu[1], Girmay Asgedom[1], Matthias Bruhn[2], Cheila Rocha[3], Melanie Galla[1], Katrin Ehrhardt[1], Michael Morgan[1], Stefan Pöhlmann[3], Ulrich Kalinke[2], Axel Schambach[1,4]

[1]Institute of Experimental Hematology, Hannover Medical School, Hannover, Germany,[2]Institute for Experimental Infection Research, TWINCORE Center for Experimental and Clinical Infection Research, Hannover, Germany,[3]Infection Biology Unit, German Primate Center, Leibniz Institute for Primate Research, Göttingen, Germany,[4]Division of Hematology/Oncology, Boston Children's Hospital, Harvard Medical School, Boston, MA

Nearly 80 variants of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) have been recorded, many of which, such as the heavily mutated Omicron variants, have rendered the existing monoclonal neutralizing antibody (nAb) treatments futile. Therefore, we developed a rapid platform to vectorize and screen anti-SARS-CoV-2 nAb codes deciphered from convalescent patient-derived memory B-cells. To achieve this, we vectorized the spike (SARS-CoV-2 envelope glycoprotein)-specific antibody codes into 3rd generation self-inactivating lentiviral vectors and produced recombinant human antibodies in HEK-293-T cells. To screen nAbs for their neutralizing capacities against viral escape, we incorporated all receptor binding domain (RBD) mutations from the recorded variants or variants

of concern (VOCs), namely Wuhan, Alpha, Beta, Gamma, Kappa, Delta+ (AY.2), IHU Méditerranée and Omicron BA.1, BA.2, BA.4/5, and engineered their replication-incompetent pseudotyped vectors (pseudoviruses) using known retroviral vectors. Using a flow-cytometric assay to detect pseudoviral infection, we screened over 90 monoclonal nAbs and identified three (C9, A7 and A9) that neutralize the Wuhan strain pseudovirus at IC_{50} concentrations of 6, 9 and 22 ng/mL respectively, similar to the approved therapeutic antibodies. While all three monoclonal nAb candidates were effective (≈70-100% neutralization) against Alpha, Beta, Gamma, Kappa and Delta+ variants, they displayed lower efficacy (≈0-50%) to neutralize the Omicron BA.1 and IHU Méditerranée variants in a monotherapeutic setting. Existing nAb cocktail therapies (e.g. REGN-COV2 and Evusheld) have demonstrated the potential of two monoclonal nAbs to circumvent viral escape. Based on this evidence, we designed and produced an innovative tetravalent bispecific candidate (A7A9 TVB nAb) against immune evasion of SARS-CoV-2 variants. A7A9 TVB nAb, which consists of four antigen-binding arms with specificity towards two distinct epitopes on the RBD, neutralized all tested VOCs better than its parental clones (except for Omicron BA.4/5, which has often been reported to evade neutralization by antibodies in other studies). Moreover, on differentiated primary nasal epithelium (DPNE, as an air-liquid interface culture) infected with authentic (full-length wild-type virus) Omicron BA.1, pre-incubation of the virus with A7A9 TVB nAb showed significantly reduced viral titers 24 hours post-infection as measured via a plaque assay on Vero E6 cells. Furthermore, stable A7A9 TVB nAb-expressing DPNE against authentic Omicron BA.1 showed a consistent decline in viral load, leading to viral clearance five days post-infection. These results strongly corroborate the clinical relevance of A7A9 TVB nAb. Additionally, to address the aspects of stability and specificity, we characterized all antibodies for their size and integrity using western blot analysis and validated their unique binding specificities through cell-based binding assays using stable cell lines expressing spike domains (S1, S2, NTD, RBD, NTD + RBD) as surface antigens. In summary, we have generated a new vectorization and screening platform for development of antibodies with modular designs that can be expanded to other infectious pathogens with urgent medical needs and beyond.

1455 Standardized Transfection: The Key to Robust and Scalable rAAV Production Processes

Julia Emmenecker[1], Amelie Bauer[1], Johannes Schott[1], Ulrike Strauss[2], Sven Markert[1]

[1]Cell Culture Technical Development Gene Therapy, Roche Diagnostics GmbH, Penzberg, Germany,[2]Material Science Pharma Technical Cell and Gene Therapy, Roche Diagnostics GmbH, Penzberg, Germany

To date, the majority of production processes for recombinant adeno-associated viral (rAAV) vectors are based on the transient transfection of HEK293-derived cell lines with plasmids containing the genetic information for essential viral components. The key challenges of these production processes are characterized by poor process robustness and scalability, particularly arising from the high complexity and variability of the transfection unit operation. This makes rAAV production processes very expensive resulting in a limited availability of gene therapies for patients. To address these challenges and increase robustness of the transfection unit operation, we started to identify and understand the critical material quality attributes of our raw materials. This forms the basis for an adequate raw material control strategy and ultimately helped us to reduce transfection variability. Going further, we developed standardized protocols for the preparation of the transfection complexes and the addition of those at various scales. Using this approach, we were able to establish a robust suspension process that is scalable from benchtop up to 500-liter scale. To further improve our understanding of the impact of raw material attributes and transfection parameters on process performance and quality attributes of the rAAV, we are evaluating methods for transfection complex characterization. We are convinced that an in-depth understanding of the transfection complex formation will accelerate the path towards more robust and scalable rAAV production processes.

1456 Next-Generation DNA-Based Delivery of Therapeutic Proteins Using MYO Technology: Preclinical Results on Filgrastim and Neutropenia

Marek Mateusz Drozdz, Andrew Cameron, Debnath Maji, Kevin Yao, Linda Sasset, Robert Miller, Andy Thompson, Mitchell Sitnick, Delcora Campbell, Liberatore Rachel

RenBio, Inc., Long Island City, NY

Therapeutic proteins, as a class of drugs, have seen a substantial increase in both clinical development and use. Any protein-based drug belongs to this class, including antibodies, hormones, engineered protein scaffolds, enzymes, interferons, anticoagulants, growth factors, and many others. Despite the broad applicability of these drugs, their more widespread use is often limited by high manufacturing costs and hurdles to delivery. Many therapeutic proteins are administered via time-consuming intravenous infusions and others, regardless of administration route, need to be dosed frequently, sometimes even daily. Another drawback of many biologics is the requirement for maintenance in a low temperature environment prior to use. Such cold-chain dependencies can significantly hinder the ability to get therapeutics to large numbers of people, a problem that is amplified in resource poor settings. MYO Technology™, a DNA-based platform for the delivery of therapeutic proteins, was developed to overcome these barriers. The MYO Technology platform consists of therapeutic-encoding plasmid DNA (pDNA) and a proprietary medical device for the intramuscular injection of pDNA, followed by the delivery of very short electrical pulses to the muscle tissue surrounding the injection site. These pulses promote the in vivo electroporation of muscle cells and uptake of pDNA, leading to production and secretion of the therapeutic protein, and ultimately uptake into peripheral circulation. Unlike many of these proteins, pDNA is simple to manufacture, and the process is less specialized. Additionally, pDNA is very stable and lacks most cold chain requirements. Moreover, administration using MYO Technology takes just a few minutes, and the serum level of a therapeutic protein can potentially be maintained for many months. This contrasts with many therapeutic proteins that require frequent dosing when administered by standard methods.One example of such a therapeutic protein is filgrastim, also known as granulocyte-stimulating

factor. It is a bone marrow stimulant, indicated for the treatment of neutropenia. Filgrastim is very potent and well tolerated by patients, but is characterized by a half-life of only ~3.5 hours and typically requires daily administration by subcutaneous injections. Severe chronic neutropenia patients may have a life-long dependency on filgrastim, and this requirement for daily drug injections not only negatively affects quality of life, but also can impact adherence to therapy.Here, we present our preclinical studies on delivery of filgrastim with MYO Technology. Animal proof-of-concept studies demonstrate that in vivo-produced filgrastim is functional and efficacious in improving neutrophil count, both in healthy animals and in mouse models of neutropenia. Expression of MYO Technology-delivered filgrastim is pDNA-dose dependent, and remains stable for several months or more. Importantly, studies in larger animal models demonstrate the ability to scale up from smaller species.Through significant improvements in administration frequency, MYO technology has the potential to dramatically improve quality of life and therapy adherence among severe chronic neutropenia patients. Furthermore, MYO Technology may present the same advantages to other therapeutic proteins with short half-lives.

1457 A Scalable, Automated Platform for Developing the Next Generation of CAR-T Therapies

Anna Bird, Miti Patel, Bin Xiao, Hugo Sinha, Philippe Vo, Andrew Chin, Alison Hirukawa

DropGenie, Boston, MA

Identifying the genetic determinants of CAR-T function is essential to engineering the next generation of cell therapies. Current methods for optimizing CAR-T employ genetic screening to identify genes that enhance CAR-T safety and efficacy. Functional profiling of such edited T cells is best accomplished using an arrayed—rather than pooled—screening approach, as arrayed screening provides superior genome coverage and allows phenotypic profiling of individual gene edits. The accessibility of arrayed screens is limited by high costs (particularly for lentiviral screens), as well as by the high cell number inputs, necessitating donor pooling and obscuring human variation. To address these concerns and enable genome-wide arrayed CRISPR screening in primary cells, we have developed a highly scalable, clog-free microfluidics platform that automates arrayed gene editing using electrostatic forces for liquid movement and the electric field for gentle payload delivery. This platform improves on existing electroporation technologies by leveraging unique cell droplet geometries that allow gentler gene delivery, improving primary cell function and viability. Here, show the results of an arrayed knock-out CRISPR screen in anti HER2 CAR-T cells, demonstrating a proof-of-concept system to optimize powerful next-generation adoptive cell therapies. We demonstrate the reduction of cell inputs from millions of cells per edit to >5,000 cells per edit, lower reagent costs by 10x and cellular inputs by 100-200x, while maintaining over 80% knock-out efficiency and no significant effect on viability. By reducing cell requirements, our system provides data at individual-donor resolution. The platform is easy to use, simple to scale to hundreds or thousands of genes, and is fully compatible with automation equipment performing downstream assays. Our platform will simplify and accelerate development of CAR-T therapies, making such optimization more accessible and affordable for experimental iteration. Refining CAR-T technology will equip cell therapies with improved cytotoxic specificity and tumor infiltration, as well as resilience against exhaustion, unleashing their full therapeutic potential. Rationally designed, highly targeted CAR-T may also achieve anti-tumor responses at lower doses, reducing toxicity in patients.

1458 Advancing NF1 Schwann Cell Targeted Therapy via Gene Regulatory Protein Development and Polymer Nanoparticle Discovery

Kenneth R. Sims[1], Niraj Rajiv Punjya[2], Danielle Huk[3], Ashlee Colbert[1], Kyle D. Fink[4], David J. Segal[5]

[1]Advanced Materials and Energetics, Battelle Memorial Institute, Columbus, OH,[2]UC Davis School of Medicine, Sacramento, CA,[3]Drug Development and Precision Diagnostics, Battelle Memorial Institute, Columbus, OH,[4]UC Davis, Sacramento, CA,[5]UC Davis Genome Center, Davis, CA

Introduction: Two key challenges remain for treatment of neurofibromatosis type 1 (NF1) patients: 1) development of a broadly applicable therapeutic approach for all NF1 patients, and 2) the ability to load and deliver large payloads (*i.e.*, CRISPR payloads >4.7 kb) to Schwann cells (SCs). To overcome these challenges, a multidisciplinary team from two different institutions is combining their payload and delivery vehicle expertise to develop a NF1 therapeutic formulation consisting of polymer nanoparticle (PNP) delivery vehicles and a DNA payload that will correct the underlying cause of NF1. This work is focused on creating targeted epigenetic regulatory proteins (ERPs) to be transient therapeutic payloads that cause persistent down-regulation of mitogen-activated protein kinases 1 and 2 (MEK1/2) and delivering plasmid DNA (pDNA) encoding these ERPs to SCs *in vitro* and *in vivo*. Methods: *Payload* - Bioinformatics tools, such as ChopChop, were used to design spCas9 guide RNAs (gRNAs) targeting the Map2k1 and Map2k2 genes. All gRNAs were chosen with the appropriate 3' NGG PAM sequence specific for *Sp*Cas9 and with varying distances in the promoter region upstream of each gene's transcriptional start site. To screen these 20 gRNAs for the strongest repressors of each gene, vectors expressing a single guide were co-transfected using Lipofectamine 3000 into Neuro2A cells. RNA expressed by pDNA was harvested, and qPCR was used to measure the repression capabilities of the different gRNA candidates. *Delivery vehicles* - PNPs were synthesized via reversible addition-fragmentation chain transfer polymerization, purified, and characterized via a proprietary design-build-test-learn PNP screening platform. PNPs were characterized for size and polydispersity using dynamic light scattering, loading efficiency via ribogreen fluorescence spectroscopy, and cytotoxicity and transfection efficiency using flow cytometry. Results: The "payload" team from the first institution designed, developed, and screened 20 gRNAs (*i.e.*, 10 Map2k1 Cas9 Guides and 10 Map2k2 Cas9 Guides). Two gRNAs were identified as promising lead candidates. For Map2k1, guide #7 of 10 showed the most promise, repressing Map2k1 expression by ~70%. For Map2k2, guide #1 of 10 showed the most promise, reducing Map2k2 expression by ~95%. In parallel, the "delivery" team from the second institution synthesized >500 PNPs with diameters of ~10 - 2,000 nm and polydispersity indices of ~0.1 - 0.57. Most PNPs showed loading efficiencies >90%,

and multiple PNPs yielded transfection efficiencies between 4-8% when tested on murine SCs *in vitro*. An indirect relationship was observed between the transfection efficiencies and cell viability values. Conclusions & Next Steps: Results suggest gRNAs for Map2k1 and Map2k2 can repress gene expression in neural cells, and future studies will seek to demonstrate these findings in SCs *in vitro*. Gene expression and MEK protein levels will also be measured over time. Initial PNP screening efforts successfully obtained size, loading efficiency, transfection efficiency, and cytotoxicity data that will be used by machine learning to enable improved PNP design and performance in future screens. PNPs will also undergo *in vivo* biodistribution screening using a proprietary barcoding platform technology to further inform future delivery vehicle designs.

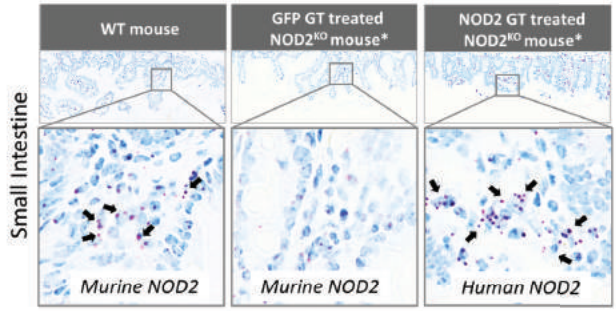
1459 Hematopoietic Stem Cell Gene Therapy as a Novel Therapeutic Approach for Severe NOD2-Deficient Crohn's Disease

Florence Enjalbert, Maria del Mar Masdeu, Tomasz Zabinski, Sam Janakan Narean, Christopher Whiting, Saranya Elavazhagan, Lily Du, Valentina Pennucci, Ana Luiz, Marina Cattoni, Paul Heal, Chiara Recchi, Bobby Gaspar, Fulvio Mavilio, Pervinder Sagoo

Translational Research, Orchard Therapeutics, London, United Kingdom

Deficiency of NOD2 (nucleotide-binding oligomerization domain containing protein 2) demonstrates the strongest genetic association to Crohn's inflammatory bowel disease (CD). Mounting evidence links NOD2 variants with poor clinical outcome, particularly in pediatric and early onset CD. CD patients with loss-of-function NOD2 polymorphisms, particularly carriers of more than one risk allele, frequently present an aggressive, fistulizing and fibrostenotic disease, requiring multiple surgical resections, and are more refractory to some available therapies. NOD2 signaling regulates gut innate immunity by sensing bacterial muramyl dipeptide (MDP) and fine-tuning Toll-like and Nod-like receptor (TLR/NLR) responses. NOD2-defective myeloid cells are implicated in CD pathogenesis, where ineffective clearance of bacterial infections drives a dysregulated, granulomatous inflammatory response. Here we present preclinical data on OTL-104, an autologous haematopoietic stem cell gene therapy (HSC-GT) which aims to stably restore NOD2 expression in gut resident macrophages, to correct the dysfunctional immune surveillance linked to NOD2-deficient CD pathogenesis. We used *in vitro* and *in vivo* models of NOD2 deficiency to evaluate the safety and efficacy of OTL-104 to restore NOD2 expression and function. NOD2^{KO} human myeloid cells differentiated *in vitro* from CRISPR-generated NOD2^{KO} CD34^{+} HSCs are unable to mount a proinflammatory cytokine response to MDP stimulation. Similarly, myeloid cells differentiated from CD34^{+} cells obtained from peripheral blood of genetically characterized NOD2-deficient CD patients, are also refractory to MDP stimulation and unable to generate a normal cytokine response profile (IL-8, TNFα, IL-6, CXCL1/2 and IL-10). Transduction with a lentiviral vector (LV) expressing NOD2 under the macrophage-restricted chimeric CathepsinG/cFES promoter fully restores NOD2-mediated IL-8 and TNFα responses in NOD2^{KO} CD34^{+} derived monocytes. In NOD2-deficient patient cells, LV transduction also restores MDP-induced cytokine responses to levels comparable to those observed in monocytes derived from CD34^{+} cells from healthy donors. Transplantation of lineage negative (*Lin*$^{-}$) hematopoietic stem/progenitor cells (HSPCs) transduced with the OTL-104 vector in NOD2^{KO} mice was used as an *in vivo* model of gene therapy for CD. Compared to wild-type mice, NOD2^{KO} mice fail to release systemic inflammatory mediators and recruit myeloid cells in response to MDP administration. Transplantation of transduced *Lin*$^{-}$ HSPCs restores MDP-induced systemic release of IL-6 and CXCL1 as well as innate mobilization of monocyte/macrophage cells. Transplanted NOD2^{KO} mice display normal hematopoiesis and stable vector copy numbers in hematopoietic cells. Key to the success of our therapeutic approach, histopathological analysis of intestinal *lamina propria* from transplanted mice shows a normal biodistribution and physiological NOD2 gene expression in tissue resident cells (Figure 1). These results confirm the negative impact of NOD2 deficiency in primary immune activation and support the therapeutic potential of OTL-104 HSC-GT for long-term correction of NOD2-deficient CD.

Figure 1. HSC gene therapy restores a normal intestinal biodistribution of NOD2 gene expression. Detection of NOD2 mRNA (*in situ* RNAScope) in intestinal lamina propria of wild-type (WT) and Gene Therapy (GT) treated NOD2^{KO} mice, confirms NOD2 gene expression is restored within hematopoietic derived tissue resident cells.



*Transplantation of gene modified NOD2^{KO} *lineage*$^{-}$ cells into NOD2^{KO} recipients following transduction with LV vectors to express GFP or human NOD2 (OTL-104 vector)

1460 Process and Platform Development for Production and Purification of CNS-Tropic Engineered AAV Capsids

Zelong Xie[1], Taeho Kim[1], David Ojala[2], Jada Padilla[1], Sandeep Yadav[1], Anthony Chikere[1]

[1]Sangamo Therapeutics, Inc., Brisbane, CA,[2]Sangamo Therapeutics, Inc., Richmond, CA

Recombinant adeno-associated virus (AAV)-based vectors for therapeutic gene delivery have shown great promise due to their favorable safety profile, broad tissue tropism, and ability to mediate stable transgene expression. Despite these advantages, conventional AAV serotypes exhibit limited delivery to the central nervous system (CNS) when employing less invasive routes of administration. An additional bottleneck to clinical translation is the design and optimization of manufacturing processes that enable large scale production and purification of AAV vectors. Modification of the AAV capsid can improve delivery efficiency and tissue specificity, however, these changes may also necessitate optimization of manufacturing process and purification conditions. In this study, we report the development of a scalable process for production and purification of engineered AAV capsids that show significantly enhanced CNS delivery relative to AAV9, the most commonly used vector for CNS gene therapy[1, 2].

Engineered AAV capsid variants were produced in suspension HEK293 cells using triple transient transfection where various production parameters including transfection reagent to DNA ratio, cell density, total DNA amount and transfection incubation time, as well as the production bioreactor systems were tested to determine the optimal AAV production process. Following AAV production, purification protocols for the different AAV capsid variants were developed using scalable affinity capture and ion-exchange column chromatography. Purification parameters such as pH and salt concentration were optimized for each engineered AAV capsid variant and for separating empty and full capsids. The optimized process demonstrates the manufacturing feasibility as well as product quality attributes that are critical to advancing novel genomic medicines to treat CNS disorders.

1461 CAR T Cells Enable Superior Control of HIV Replication through Recognition of Abundant Antigens and Rapid Killing of Infected Cells

Yuqi Zhou, Julie Jadlowsky, James L. Riley
University of Pennsylvania, Philadelphia, PA

Antigen-specific adoptive T-cell therapy has shown significant progress in treating different types of blood cancers, making it a promising therapy to limit the spread of chronically infected viruses such as HIV to reach a functional cure. Chimeric Antigen Receptor (CAR) and TCR αβ chains are the most common antigen recognition molecules engineered into T cells for redirection in adoptive T cell therapy. Although TCRs are shown to be >100 fold more sensitive than CARs, previous data from our lab has shown superior HIV suppression *in vitro* by CD4 extracellular-domain CAR-T cells compared to HIV-specific TCR-T cells, and the mechanism of CAR's superiority remains to be elucidated. Here, by demonstrating the timely induction of active-Caspase-3 within HIV infected cells by TCR and CAR-T cells, we show that CAR-T cells' superior control over HIV is a result of fast elimination of HIV infected cells. The reduced ability of HIV_{Pol} TCR to control HIV spread is due to low presence of pMHC antigen target, preventing elimination of infected cells before new virions are made and spread. Our research provides a mechanistic explanation for the superiority of CD4 CAR-T cells in vitro, highlights the difference between cancer and virus immunotherapy, and will inform novel TCR and CAR adoptive T cell therapies against HIV.

1462 Scalable Recombinant Adeno-Associated Virus (rAAV) Production in HEK293 Cells with the Use of a Histidine-Rich Peptide as Transfection Reagent

Baran Arslan, Irina Perevoshchikova, Julie Gardin, Pauline Bourbon, Helai Arabshahi, Tomas Cinek, Shilpa Shroff, Javier Femenia, Yvette Tang
Drug Substance Technologies, BioMarin Pharmaceutical, Novato, CA

Production of viral vectors in mammalian cells requires the delivery of foreign nucleic acids coding the gene of interest and necessary proteins involved in viral vector production. Most commonly, a transfection reagent (TR) is used to shuttle the nucleic acids into the cells. The choice of the transfection reagent for large scale manufacturing of viral vectors is governed by its efficiency, consistency, scalability, and cost. A suitable transfection reagent should meet several criteria to be a successful candidate for large scale viral vector production in mammalian cells. Stable DNA:TR complexes and low complexation volume are of special interest when scalability is considered. Currently, most of the commercially available transfection reagents lack one or more of the criteria mentioned above. Histidine rich peptides (HRPs) are known for their ability to deliver nucleic acids and proteins to target cells. However, to our best knowledge, their application to large scale viral vector production has not been reported. Here, we highlight the key benefits of the use of histidine rich peptide as transfection reagent in rAAV production process in HEK293 cells. These benefits include high transfection efficacy, industry leading rAAV yield with >1e12 Vg/mL, and scalability of transfection process facilitated by the stability of HRPs:DNA complexes and low HRPs:DNA complexation volume.

1463 A Cell-Based Drug Factory with Bioelectric Based Time and Dosage Control for Regulation of the Circadian System

Samantha Fleury[1], Cody Fell[1], Jacob Goell[1], Matthew Parker[2], Jing Li[1], Scott Beard[3], Martha Hotz Vitaterna[4], Jonathan Rivnay[3], Jacob Robinson[2], Isaac Hilton[1], Omid Veiseh[1]
[1]Bioengineering, Rice University, Houston, TX,[2]Electrical and Computer Engineering, Rice University, Houston, TX,[3]Biomedical Engineering, Northwestern University, Evanston, IL,[4]Center for Sleep and Circadian Biology, Northwestern University, Evanston, IL

Background: Circadian rhythms are vital regulators of cyclical biological functions including metabolism and endocrine signaling. Dysregulation of the circadian system is a common problem faced by shift workers and travelers among others. Beyond the immediate detrimental impact to cognitive and physical function, disruption of the circadian rhythms are associated with negative health outcomes including increased risk of metabolic diseases, mental health disorders and some cancers. Light is a powerful regulator of the central circadian clock, however, alternative cues including metabolic and endocrine signals also play a role in regulating the circadian clocks and can be modulated therapeutically. An important challenge for regulating the circadian system is the need for a precisely timed therapy to influence the dynamic biologic process. Interfacing cell-based therapeutics with bioelectronic devices can enable timing and dosage control in addition

to cell health maintenance and monitoring. We utilized cells' innate ability to produce bioactive peptide therapeutics in combination with advances in synthetic biology to create a cell-based drug factory capable of producing metabolic and circadian rhythm modulating therapies on demand. **Methods:** We engineered a clinically relevant epithelial cell line to express endocrine signals demonstrated to regulate the circadian rhythm (leptin, and adrenocorticotropic hormone (ACTH)) under the control of a light responsive optogenetic system. We then validated these cells *in vitro* and characterized the productivity of the engineered cells in response to varying light intensity and time. Engineered cells were then encapsulated in silicone and hydrogel-based devices to isolate the therapy from the immune system and implanted in mice to evaluate *in vivo* therapeutic production. **Results:** Our results demonstrate that a clinically relevant cell line can be engineered to secrete therapeutically relevant peptides on demand. Engineered cells increased production of ACTH 34-fold and leptin 324-fold in response to light exposure. Further testing demonstrated this induction level is tunable based on light intensity and duration allowing for titratable therapeutic dosing. We determined that engineered cells can be turned on repeatedly over the course of days without a decrease in ACTH or leptin production, which allows for repeated, long term therapeutic dosing from a single engineered cell dose. When implanted in a mouse model, engineered cells remained viable and productive and were able to deliver the peptide therapeutic *in vivo*. **Conclusions:** In summary we demonstrated that clinically relevant cells can be used as cell-based drug factories to produce peptide based circadian regulators on demand. Therapeutic production can be timed and tuned based on user defined light input enabling precise dosing control. These cells have the potential to advance therapeutic circadian rhythm modulation. Additionally, due to its potential to produce any peptide based therapeutic this technology can function as a platform for the treatment of a wide array of indications.

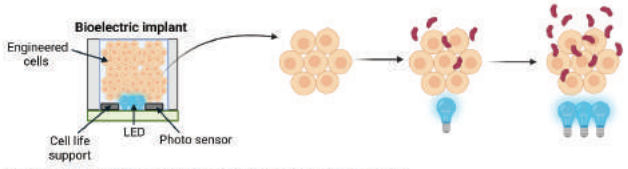

Figure 1: Overview of bioelectric implant and therapeutic dosing control

1464 A Comprehensive AAV Tropism Profile in Mice, Crab-Eating Macaques, and Marmosets

Kailun Fang[1,2], Guannan Geng[2], Xiali Yang[2], Junhui Xia[1], Ruoxi Wu[1], Weiya Bai[1], Linyu Shi[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Recombinant adeno-associated viruses (rAAV) have become popular as gene delivery vehicles and development of gene therapy products. It is well-accepted that different AAV serotypes have different affinities for particular cell types. To make AAV-based gene delivery more accessible, several newly engineered AAV capsids were developed to target central nervous systems and muscles. However, comprehensive AAV tropism of wild-type AAV and new AAV serotypes among organs of different rodent and non-human primate (NHP) species remains unknown. **Methods**: 21 AAV serotypes, including AAV1-9, rh10, rh74, DJ, IE, LK03, B1, HSC15, PHP.B, PHP.eB, PHP.S, CAPB10, and Myo2A, containing CAG-H2B-tdTomato-barcode-WPRE constructs were mixed as an AAV pool and were intravenously injected to C57BL/6J mice, BALB/cJ mice, crab-eating macaques (Fig. 1A,B), and marmosets. Three weeks post injection, 20 tissues of mice and 29 tissues of NHPs were collected and examined for tandem-dimer tomato (tdTomato) expression and viral transduction efficiency. **Results**: The AAV transduction efficiency was found quite different across species. Although AAV-pool transduction was enriched in the glomerulus of the kidney and islet of the pancreas in mice, this sub-organ preference was not observed in NHPs. Besides, particular AAV serotypes showed different tropisms among species. For instance, AAV-PHP.b, PHP.eB and CAPB10 showed a high DNA transfection and RNA transduction in C57BL/6J mice, but low in BALB/cJ mice, and NHPs (Fig. 1C-E). In addition, even though PHP.S performed average in mice, the transduction efficiency of AAV-PHP.S showed high in most organs in NHPs (Fig. 1E). Since several AAV serotypes showed good transduction efficiency in some specific organs, a separate AAV serotype injection to mice or a smaller pool of AAV combination to NHPs was carried out as a confirmation. AAV4 exhibited significantly high DNA and RNA transduction among organs such as lungs, kidneys, and pancreas in mice and NHPs. Furthermore, AAV-PHP.S was broadly transduced among organs in NHPs when AAV4-tdTomato, AAV9-EGFP, and AAV-PHP.S-mBFP-HA were co-injected into NHPs. **Conclusions**: Our finding provides a comprehensive AAV tropism analysis based on barcode DNA and cDNA sequencing in C57BL/6J, BALB/cJ, crab-eating macaques, and marmosets. Additionally, our data characterizing AAV tropism in different species provides further guidance in engineering and use of gene delivery vehicles, which is applicable to AAV serotype selection for gene therapy to treat different therapeutic areas.

1465 Optimization of Packaging Efficiency for Adeno-Associated Virus by Evaluating Production Process Parameters Using Ambr 250® High-Throughput Platform

Tsai-Yu Chen[1], Peng Wang[2], James McAllister[3], Tam Duong[2], Xiang Gao[2], Bingnan Gu[2], Wenling Dong[1]

[1]Process Development, Lonza Houston Inc., Houston, TX,[2]Research & Development, Lonza Houston Inc., Houston, TX,[3]Applied Statistics, Lonza, Portsmouth, NH

The packaging efficiency (full to total capsid ratio, F/T ratio) for AAV is one of the critical quality attributes for the manufacturing and commercialization of AAV-based gene therapy. According to available literature and our data, production of AAV using the triple transfection method resulted in approximately 5 to 50 % of full AAV capsid in upstream crude harvest depending on serotype or gene of interest (GOI). The low quality of upstream crude harvest poses challenges for downstream purification. Previously, the lack of a reliable and cost-effective analytical tool to measure the F/T ratio on upstream crude harvest provided a major gap for upstream process development. ELISA-based approach coupled with genomic titer analysis is usually the method to estimate the F/T ratio for upstream crude harvest or other in-process samples. However, the data obtained by this approach are often unreliable and ambiguous due to low accuracy and high assay variations. Other more reliable analytical tools for F/T analysis, such as AUC (Analytical Ultracentrifugation) or negative staining TEM (Transmission Electron Microscopy), and cryo-EM (Cryogenic electron microscopy) are difficult to apply to upstream crude harvest due to low titer and high impurities in these samples while the cost for these assays is very high. Recently, several new analytical methods have been developed that can provide accurate and cost-efficient ways to analyze the F/T ratio for upstream crude samples. In this study, by using a Design of Experiment (DOE) approach, we sought to evaluate the impact of several production process parameters on AAV titer and packaging efficiency using the Ambr 250® High-Throughput Platform. We utilized our proprietary AAV packaging plasmids and AAV8-GFP as the study model. Titer and the F/T ratio on upstream crude samples were analyzed using the ddPCR titer assay and SEC-UV-MALS (Size-Exclusion Chromatography coupled with Ultraviolet and Multi-Angle Light Scattering detectors) analysis, respectively. After conducting two rounds of DOEs, we were able to significantly increase the full percentage of AAV-GFP in crude harvest by approximately 3-fold from the baseline. Additionally, we identified several production process parameters that played important roles in packaging efficiency for AAV8-GFP and built a strong model based on the DOE to predict an optimal condition for maximizing packaging efficiency for AAV8-GFP. In summary, this study demonstrates that we can significantly increase the AAV packaging efficiency at the upstream production stage, and a similar approach is ready to be implemented into upstream process development for different AAV serotypes and client-specific GOIs.

1466 Identification of Novel Inflammation-Inducible Promoters Using a Hybrid-Barcoded SuRE™ Library

Kassiani Kytidou[1], Sabine Van Der Sanden[1], Bart Kok[1], Marleen Van Loenen[1], Alexandria Forbes[2], Joris van Arensbergen[3], Janneke JM Meulenberg[1]

[1]MeiraGTx Netherlands B.V., Amsterdam, Netherlands,[2]MeiraGTx, New York, NY,[3]Annogen, Amsterdam, Netherlands

AAV-based gene therapy vectors are promising candidates for the treatment of inflammatory disease, resulting from a biological response of the immune system triggered by a variety of different factors. Regulatory elements, including promoters and enhancers, are engineered for use in AAV vectors to optimize the strength, kinetics, and specificity of transgene expression. The incorporation of promoters inducible by inflammation will help to reduce the risk for side effects due to overexpression of and/or continuous exposure to the anti-inflammatory therapeutic protein by such AAV vectors. The aim of this study was to identify inflammation-inducible hybrid-promoters and/or *cis*-regulatory elements that show improved inducibility and/or higher expression compared to the reference inflammation-inducible promoter NFkB-responsive CMV (NFkB-CMV promoter). To this end, the Survey of Regulatory Elements (SuRE) methodology was applied to identify new *cis*-regulatory elements in the human genome. A barcoded library containing around 300 million human DNA fragments/elements, with an average insert size of about 300 base pairs (bp), was generated and used to transfect HT1080 cells. Transfected HT1080 cells with and without stimulation with TNF alpha (TNFα) and IL-1 beta (IL-1β) human recombinant cytokines were analyzed for expression levels of the ~300 million elements as compared to their frequency in the input library to generate a genome-wide profile. Elements displaying high expression in stimulated conditions compared to unstimulated conditions were selected from the SuRE screening and combined with the reference NFkB-CMV promoter to generate a new barcoded library, consisting of ~40,000 new hybrid combinations, each of around 600 bp in size. The new barcoded hybrid-library was subsequently used in a second round of screening in HT1080 cells. The best performing hybrid-elements were selected for further analysis in the context of the AAV2 genome upon plasmid transfection and AAV transduction, with luciferase as reporter protein. Primary cells and different cell lines were used to determine the strength and inducible character of the new hybrid promoters. The expression profiles from plasmids and AAV viruses revealed a number of new hybrid promoter elements that displayed improved inducibility and/or higher expression under inflammatory conditions compared to the reference NFkB-CMV promoter.

1467 Engineered Virus-Like Particle to Deliver CRISPR-Cas9 Ribonucleoprotein with Minimal Off-Target Effects

Zihua Jiang[1], Limei Ai[1,2], Miao Yu[1], Bang Wang[3], Zongli Zheng[1,2]

[1]Ming Wai Lau Centre for Reparative Medicine, Karolinska Institutet, Hong Kong, Hong Kong,[2]Department of Biomedical Sciences, City University of Hong Kong, Hong Kong, Hong Kong,[3]GenEditBio Limited, Hong Kong, Hong Kong

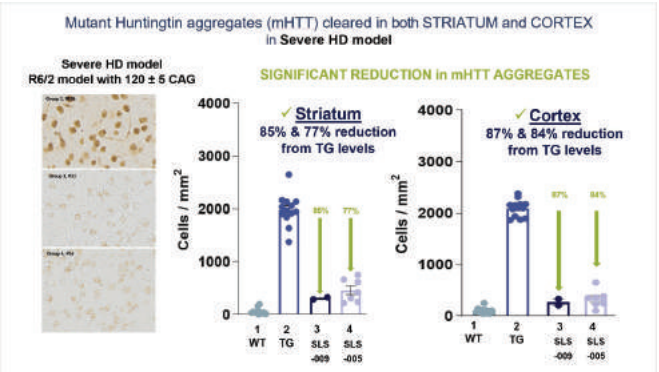
Gene editing using the CRIPSR-Cas9 system is promising to treat many genetic diseases with unmet needs. Transient delivery and prompt editing of the CRISPR-Cas9 system is highly desirable with the goal to minimize its genome off-target effects, especially when delivered in vivo systematically. The development of engineered virus-like particle (eVLP) systems to deliver Cas9 ribonucleoprotein (RNP) that allows for rapid genome targeting as well as degradation of the Cas9 protein is therefore promising to control the off-target effect of CRISPR-Cas editing systems. Here we engineered a VLP containing the wildtype SpCas9 and a *TTR* gene targeting sgRNA. We evaluated the off-target effect of the SpCas9-*TTR* eVLP and compared it with the liposome-based CRISPR RNA. Two methods were used for genome-wide off-target evaluation, namely the GUIDE-Seq and a method for editing event detection (EDITED-Seq). Briefly, we recently developed the EDITED-Seq method for simultaneous identification and verification of new, known, and predicted potential off-target sites, and is compatible with regular gene editing protocols without extra cell manipulations. To produce the SpCas9-*TTR* eVLP, four plasmids (VSV-G, MMLV gag-pol, MMLV gag-SpCas9 and *TTR*-targeting sgRNA plasmids) were co-transfected into LentiX-293T cells. At 72h post-transfection, the supernatant was harvested, purified, and concentrated 100-fold. The eVLPs produced (50 uL) were then used to transduce HEK293T and HepG2 cells in 24-well plates (pre-treated with dsODN for GUIDE-Seq analysis). Similarly, liposome-based RNA (at 15 nM sgRNA concentration and a weight ratio of sgRNA:mRNA being 1:1) transfections targeting the same site were conducted on both cell lines. At 48h after transduction or transfection, cell genomic DNA was harvested, and 400 ng DNA was used for next-generation sequencing for GUIDE-Seq and EDITED-Seq analyses. The GUIDE-Seq results showed that the eVLP method had no detectable off-targets in both cell lines (with the on-target site showing thousands of unique GUIDE-Seq reads), whereas the liposome-based RNA method showed several off-target sites (5 to 7 among triplicates). The EDITED-Seq showed consistent results with GUIDE-Seq, except that one off-target site was detected from the eVLP method samples. This off-target site was the top off-target site (with the most abundant GUIDE-Seq reads) detected in the liposome-based RNA method. The data provides genome-wide unbiased evidence that using eVLP to deliver CRISPR-Cas9 ribonucleoprotein may substantially reduce off-target effects than the liposome-based RNA delivery, likely due to faster degradation of the RNP complex. Further studies on more targets, more cell lines and in vivo settings are needed to fully characterize the potential minimal off-target effects associated with eVLP delivery.

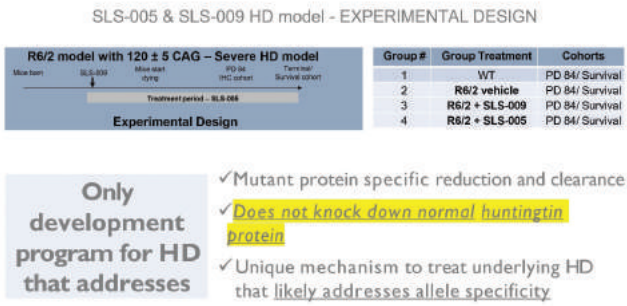
1468 SLS-009 Clears Only Mutant Huntingtin Aggregates in a Severe Huntington's Disease Mice Model

Krishna Subramanian, Raj Mehra

Seelos Therapeutics Inc., New York, NY

Huntington's disease (HD) is a fatal dominantly inherited neurodegenerative disorder caused by CAG repeat expansion (> 36 repeats) within the first exon of the huntingtin gene. Although the huntingtin protein is ubiquitously expressed, the neuropathology of HD is characterized by progressive decline in motor, cognitive and various psychiatric functions involving striatum and cortex regions of the brain. There is currently no disease-modifying treatment. The severe juvenile form of the disease with > 60 CAG repeats has the closest resemblance to the R6/2 HD rodent model utilized here with ~ 120 CAG repeats. This is a severe rodent phenotype that rapidly progresses and has the distinct mutant Huntingtin (mHTT) aggregates present inside cells in the striatum and cortex regions. Upon delivery of two therapeutic agents, SLS-005 (administered starting on Day 31) and SLS-009 (also administered on day 31) to two separate groups of R6/2 rodents, along with two additional groups of wildtype and transgenic controls (positive and negative controls) resulted in significant reduction of the mHTT aggregates in striatum and cortex regions by Day 84. We quantified an 85% and 77% reduction with SLS-009 and SLS-005, respectively, in mutant aggregate counts in the striatum and an 87% and 84% reduction respectively in the cortex, compared to the diseased animals. Corresponding biomarker, DARPP-32, supported the above findings with reductions of similar magnitude. Trehalose has been described in the past in several in-vitro and in-vivo experiments to have benefits in HD and other neurological disorders. However, the past doses and administration paradigms were not uniform and led to mixed observations in the literature. Here, we demonstrated overcoming the previous limitations with new formulations (SLS-005 and SLS-009) and appropriate therapeutic dosing to elicit disease-modifying benefit in two critical regions of the brain in this severe R6/2 HD model. The therapy is currently believed to be the only one in development for HD treatment that addresses the clearance of mutant huntingtin protein alone and is potentially allele-specific, as the wild-type huntingtin protein is unaffected through the unique mechanism of action of SLS-009 and SLS-005.





1469 A Novel, Chemically-Defined, Serum-Free Cell Culture Medium for Expansion of Transfected T Cells

Valeria Annibaldi

Lonza GmbH, Cologne, Germany

T cell therapies require ex vivo culture and expansion of cells at scales relevant for therapeutic applications. Human AB serum (HAB) or fetal bovine serum (FBS) have been key components of the cell culture media used in T cell therapy manufacturing processes. Although these components assist in optimal growth and improved gene transfer efficiencies, they have inherent variability and supply challenges. In addition, due to animal origin and traceability issues, they have a potential of introducing pathogens to the process. Without the addition of HAB or FBS, T cells, especially when patient derived, fail to grow adequately and exhibit reduced efficiencies of gene transfer, irrespective of the transfection method applied. In the transfection arena, electroporation offers a powerful non-viral delivery method for T cell engineering. In this study, we present data generated by utilizing a novel, chemically-defined, animal component free cell culture medium that robustly expanded human T cells in the absence of serum and worked well in combination with electroporation as demonstrated by high transfection efficiency and cell proliferation. Data were generated using activated T cells obtained by stimulating CD3 cells or PBMC. The recovery, proliferation and expansion profiles of the cells post transfection demonstrate efficiency and consistency of the electroporation technology utilized. These results suggest that the new chemically-defined, serum-free medium along with the electroporation technique employed can support scalable GMP manufacturing of clinical-grade T cell therapies.

1470 Primary CD4 T-cell Biofactory for Antigen-Inducible *In Situ* Synthesis of Engineered Proteins

Harikrishnan Radhakrishnan[1], Sherri Newmyer[1], Marvin A. Ssemadaali[1], Harold S. Javitz[2], Parijat Bhatnagar[1]

[1]Biosciences Division, SRI International, Menlo Park, CA,[2]Education Division, SRI International, Menlo Park, CA

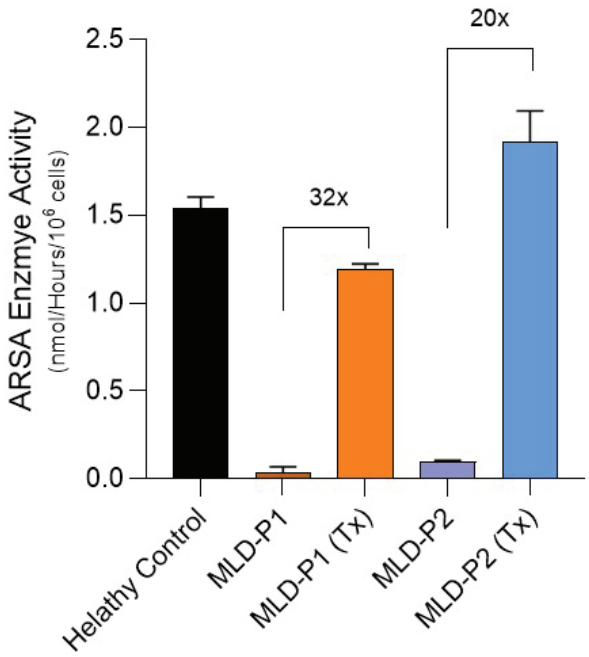
Toxicity associated with systemic delivery of drugs limits its application for diseases that evolve *in vivo* (e.g. cancer, autoimmune diseases and viral infections). T-cell Biofactory is an engineered cell-based platform that capitalizes on T-cell's innate extravasation capability and transforms cells into a living vector that assesses the disease burden and synthesizes calibrated amounts of complex protein-based biologics with desired properties at the disease site. This offers the potential to exert a broad range of functions without any dose misalignment, which otherwise causes side effects. Clinical translation of this technology has however been impeded by insufficient expression of the biologics from the T cell and manufacturing bottlenecks specific to the T-cell products. Compared to the pan T cells, the CD4 T cells offer to overcome these challenges due to their propensity for higher transduction, faster expansion, and a more productive transcription machinery. The results presented herein show that capitalizing on the CD4 T-cell biology, the CD4 T-cell Biofactory, compared to its CD8 counterpart, when configured with chimeric antigen receptor (CAR), transduces ~3-fold better, expands ~2-fold more, induces biologics ~5-fold more, and exhibits minimum cytolytic activity. Additionally, we also report on a scalable, simple yet efficient method for manufacturing primary human T-cell Biofactories encoded with large genetic payloads. Altogether, the correctly configured CD4 T-cell Biofactory is a cell-based system that may synergize with a reduced dose of other directly acting therapies to exert desired efficacy while mitigating any morbidity associated with its overdosing.

1471 A Mutation Agnostic Hematopoietic Stem Cell GeneTherapy for Metachromatic Leukodystrophy

Justin S. Antony

University Children's Hospital, Tuebingen, Germany

Metachromatic leukodystrophy (MLD) is a rare genetic disorder caused by mutations in the Arylsulfatase-A (ARSA)gene. The enzyme plays a key role in sulfatide metabolism in brain cells, and its deficiency leads to neurodegeneration.The clinical manifestations of MLD include stagnation and decline of motor and cognitive function, leadingto premature death with limited standard treatment options. Here, we describe a mutation-agnostichematopoietic stem and progenitor cell (HSPC) gene therapy using CRISPR-Cas9 and AAV6 repair template asa prospective treatment option for MLD. Our strategy achieved efficient insertions and deletions (>87%) anda high level of gene integration (>47%) at the ARSA locus in human bone marrow-derived HSPCs, with no detectableoff-target editing. As a proof of concept, we tested our mutation-agnostic therapy in HSPCs derivedfrom two MLD patients with distinct mutations and demonstrated restoration of ARSA enzyme activity (>30-fold improvement) equivalent to healthy adults. In summary, our investigation enabled a mutation-agnostic therapyfor MLD patients with proven efficacy and strong potential for clinical translation.



1472 Evaluating the Permissibility of Human iPSC-Derived Cell Types to AAV Transduction as an *In Vitro* Model for Gene Therapy

Ravi Vaidyanathan[1], Jerrimesia O. Hamilton[2], Ashikun Nabi[2], Vitaliy Dernov[2], Sara Mata[2], Anne Peters[2], Xuan Xu[1], Emigdio Reyes[2], Coby B. Carlson[1]

[1]FUJIFILM Cellular Dynamics Inc., Madison, WI,[2]FUJIFILM Diosynth Biotechnologies Texas, College Station, TX

INTRODUCTION: The differentiation of induced pluripotent stem cells (iPSC) into specialized cell types of the human body represents a major advancement for the development of biologically relevant disease models. Generation of patient-specific cell models for in vitro testing has cultivated the concept of "disease-in-a-dish" for iPSC-based disease modeling. These model systems are increasingly being used to evaluate various gene targeting approaches, including adeno-associated viral vectors (AAV), to directly correct the genetic defect or mutation. The use of AAV for gene therapy has recently become a clinical reality for the treatment of spinal muscular atrophy (SMA) and a rare form of blindness. To identify relevant iPSC-based in vitro models to support the analytical characterization of AAV gene therapies, the permissibility of different iPSC-derived cell lines to specific AAV serotypes needs to be defined. This requires the establishment of an efficient protocol for the AAV transduction of a particular iPSC-derived cell type, for which several aspects need to be optimized, including viral vector serotype, multiplicity of infection (MOI), choice of promoter, transduction media, and timing of transduction. **METHODS:** Human iPSC-derived cell types included commercially available iCell® Cardiomyocytes (iCell CM) and iCell Retinal Pigment Epithelial Cells (iCell RPE) from FUJIFILM Cellular Dynamics, Inc. (FCDI). Cryopreserved cells were thawed, plated, and maintained in culture according to the manufacturer's recommendations until the time of transduction. AAV viruses engineered to express green fluorescent protein (GFP) were prepared internally or obtained commercially. Different methods to evaluate transduction efficiency included standard fluorescence microscopy to visualize GFP-positive cells, flow cytometry (CytoFLEX, Beckman Coulter) to quantify green cells, and Celigo image cytometer (Nexcelom) to both obtain images and quantify GFP in situ. **RESULTS:** iCell CM and iCell RPE were transduced with AAV1, -2, -4, -5, -6, -8, and -9 in standard maintenance medium and serum-free medium on days 7 and 10 post-thaw for iCell CM and days 14 and 21 post-thaw for iCell RPE. AAV6 showed the highest transduction efficiency in iCell CM, with AAV2 also working well. AAV2 show high transduction efficiency in iCell RPE. However, the capability of other AAV serotypes to transduce iCell RPE remains to be tested. In general, transduction on the earlier timepoint, day 7 for iCell CM and day 14 for iCell RPE, worked better than on the later timepoint, day 10 for iCell CM and day 21 for iCell RPE, with some exceptions. Moreover, the CAG promoter drove higher transgene expression than CMV. In addition to vector tropism, comparison of iPSC-CM and iPSC-RPE show that cell type significantly affects transgene expression. **CONCLUSION:** Human iPSC-derived cells can be efficiently transduced with AAV. The systematic exploration of the numerous variables that impact the efficiency of AAV transduction for any given cell type is required. Cryopreserved cells from commercial sources that are manufactured reproducibly in scale are an ideal reagent for use in these studies because of their "thaw-and-go" consistency. Proper handling and storage of AAV material is critically important as it can affect the transduction efficiency. Finally, the combination of iPSC derived cells and AAV technology to modulate in vitro cellular disease models for pre-clinical studies and potentially even potency release assays is a powerful system that is now available as part of a drug manufacturing process for material release.

1473 Novel Peptide Sequences to Fuse to Iduronate-2-Sulfatase for the Treatment of Mucopolysaccharidosis Type II

Shaun R. Wood[1], Ahsan Chaudrhy[1], Stuart M. Ellison[1], Aiyin Liao[2], Hélène Gleitz[3], Gabriella Forte[1], Claire O'Leary[1], Rachel Searle[1], Constance Burgod[1], Ghazala Tehseen[1], Brian W. Bigger[1]

[1]University of Manchester, Manchester, United Kingdom,[2]University College London, London, United Kingdom,[3]Erasmus MC, Rotterdam, Netherlands

Mucopolysaccharidosis Type II (MPSII) is a lysosomal storage disorder caused by a deficiency in the Iduronate-2-Sulfatase (IDS) enzyme due to a mutation in the *IDS* gene. The resulting accumulation of glycosaminoglycans (heparan sulfate (HS) and dermatan sulfate (DS)) leads to a multisystem disease with neurodegeneration in two thirds of patients. Enzyme replacement therapy is ineffective at treating neurological disease, as the blood-brain-barrier (BBB) prevents the entry of intravenous enzyme into the brain. Haematopoietic stem cell transplant is also unsuccessful, presumably due to insufficient enzyme production from transplanted cells engrafting in the brain. The fusion of peptides to lysosomal enzymes has the potential to increase the amount of enzyme reaching the brain from the periphery by enabling greater uptake of enzyme into the brain. We have previously demonstrated that a haematopoietic stem cell gene therapy (HSCGT) strategy, using a lentivirus containing IDS fused to ApoEII (LV.IDS.

ApoEII), can correct neuropathology in MPSII mouse models to a greater extent than IDS alone. Here we present data using two other peptides, RVG (rabies virus glycoprotein) and gh625 (Herpes virus glycoprotein derived peptide), fused to IDS and delivered via HSCGT in MPSII mice. Both peptides have been shown to increase delivery of drugs across the BBB into the brain. There were encouraging reductions in pathology with both IDS.RVG and IDS.gh625, however enzyme levels in the brain were lower than ApoEII (<20% of ApoEII for both). Also, both IDS.RVG and IDS.gh625 constructs failed to completely normalise inflammation and lysosomal swelling in the brain. We have therefore also screened several other peptide constructs (IDS.HS2 and IDS.HS5) for their ability to increase uptake into the brain using an *in vitro* BBB uptake assay. HS5 was able to improve BBB uptake over ApoEII (65% increase) and also improved uptake into multiple cell types including cardiomyocytes (37%), retinal pigment epithelium (105%) and osteoblasts (116%). HS5 also increased transcytosis across BBB cells over native IDS and to the same extent as ApoEII. We believe that HS5 may, therefore, may prove to be a viable candidate for stem cell gene therapy for Mucopolysaccharidosis Type II.

1474 CRISPR/dCas9 Based Epigenetic Manipulation of Cancer Cell Line HepG2 for Modulation of Epithelial to Mesenchymal Transition

Nika Foglar[1], Goran Josipović[2], Fran Lukšić[1], Ana Vujić[1], Marija Klasić[1], Vedrana Vičić Bočkor[1], Vlatka Zoldoš[1]

[1]Department of Biology, Faculty of Science, University of Zagreb, Zagreb, Croatia,[2]Genos Glycoscience Research Laboratory, Zagreb, Croatia

Epigenetic mechanisms are critical in communication between environment and genome, thus playing an important role in many diseases, including cancer. Molecular tools have been developed for targeted and specific manipulation of epigenetic modifications, including the CRISPR/dCas9 system, that enables studying interplay of different epigenetic marks and their effects on gene expression. Fusion of different epigenetic modifiers to the inactivated dCas9 allows for introduction of desired epigenetic modification in the genome region of interest. In this study, we investigated interactions between DNA methylation and histone modifications, and the effects of these epigenetic marks on the activity of two genes, *ZEB1* and *SNAI1,* coding for transcription factors involved in epithelial to mesenchymal transition (EMT). To achieve this, we used the DNMT3A-dSpCas9 fusion for targeted DNA methylation in combination with dCas9 fusions with different histone modifying effectors domains: G9a-SET for induction of H3K9 mono and di-methylation, G9a-Y1154F-SET for H3K9 trimethylation, LSD1-SET for H3K4me1/2 demethylation, and the catalytic domain of KDM5a for H3K4me3 reduction. Multiple gRNAs were used to target the entire CpG islands of *ZEB1* and *SNAI1* genes in the HepG2 cell line. A synergistic effect of the G9a-dSpCas9 and DNMT3A-dSpCas9 was observed on both *ZEB1* and *SNAI1* gene expression, while the synergy effect on DNA methylation was observed only in *SNAI1* gene promoter. Interestingly, none of the effector domains themselves were able to increase DNA methylation level. However, in combination with DNMT3A, domains G9a, G9a-Y1154F and LSD1 increased DNA methylation level on one or both targeted genes, in comparison to DNMT3A combined with the inactive version of the domains. Only KDM5a did not affect CpG methylation when combined with DNMT3A, but still showed synergistic effect on the expression level of both genes. When DNMT3A-dSpCas9 was combined with either G9a-Y1154F or LSD1, it too showed synergistic effect on transcriptional silencing of the targeted genes. These manipulations resulted in decrease of the protein levels of targeted genes, and changed expression of EMT markers, CDH1 and CRB3. The results obtained in this study suggest that different epigenetic modifications (cytosine methylation and histone marks) operate in synergistic manner, on both the expression of selected genes, and DNA methylation. Ongoing research will provide more mechanistic insights into understanding the relationship between DNA methylation and histone modifications.

1475 Process Improvements to Enhance AAV Recovery

Catherine Grimm, Ana Castro, Sheryar Khan, Mahsa Hadidi

Sanofi, Waltham, MA

Improving purification recovery of AAV products is an industry-wide goal; however, this is particularly challenging for AAV serotypes that are prone to aggregation due to their physicochemical properties. The aggregation propensity impacts product stability at various process conditions and adversely impacts the recovery. This presentation will discuss the process development challenges associated with AAV aggregation and the opportunities identified to alleviate the impact on AAV recovery. In AAV purification processes, affinity chromatography with low pH elution is commonly used. However, low pH conditions with extended hold time were demonstrated to promote high levels of aggregation, which impacted subsequent unit operations. To mitigate such risks, an in-situ neutralization strategy was developed to control the aggregation levels. In addition, the anion exchange chromatography was optimized to remove aggregates, and the location of the virus filtration step was optimized to further improve process recovery.

1476 Base Editing of Hematopoietic Cells Restores Immune Function in a Mouse Model of Familial Hemophagocytic Lymphohistiocytosis

Lei Lei[1], Jessica Lao[2], Viviane Dettmer-Monaco[1], Kristoffer Weißert[2], Sandra Ammann[2], Masako M. Kaufmann[1], Manuel Rhiel[1], Linda Gräßel[3], Jamal Alzubi[1], Julian Grünewald[4], Bret R. Miller[4], Geoffroy Andrieux[5], Melanie Boerries[5], Anna Lena Illert[3], J. Keith Joung[4], Tatjana I. Cornu[1], Stephan Ehl[2], Peter Aichele[2], Toni Cathomen[1]

[1]Institute for Transfusions Medicine and Gene Therapy; Center for Chronic Immunodeficiency, Medical Center – University of Freiburg, Freiburg, Germany,[2]Institute for Immunodeficiency; Center for Chronic Immunodeficiency, Medical Center – University of Freiburg, Freiburg, Germany,[3]Department of Internal Medicine I, Medical Center – University of Freiburg, Freiburg, Germany; German Cancer Consortium (DKTK), Partner Site Freiburg & German Cancer Research Center (DKFZ), Heidelberg, Germany,[4]Molecular Pathology Unit, Massachusetts General Hospital, Charlestown, MA, USA; Department of Pathology, Harvard Medical School, Boston, MA,[5]Institute of Medical Bioinformatics and Systems Medicine, Medical Center – University of Freiburg, Freiburg, Germany

Familial hemophagocytic lymphohistiocytosis (FHL) is an immunohematologic disorder caused by hyperactivated T cells and macrophages that lead to severe inflammation and multiorgan damage. The uncontrolled immune activation is a result of impaired lysis of antigen-presenting cells due to defective cytolytic activity of T cells and NK cells. The disease-causing mutations in FHL type 3 (FHL3), which accounts for one third of FHL cases, are found in the *UNC13D* gene. Given that current treatment protocols, including allogeneic hematopoietic stem cell (HSC) transplantation, still show high mortality, novel treatment options are needed. As a proof of concept, we developed a base editing strategy to amend the disease-underlying mutation in *Jinx* mice - a preclinical model for FHL3. We generated several adenine (ABE) and cytosine base editors (CBE) to target the cryptic splice donor site in *Unc13d* intron 26. Screening in specifically generated reporter cells resulted in functional correction of 65-96% of cells. The best-performing base editors were applied to primary hematopoietic cells. To this end, ABE/CBE-encoding mRNA and corresponding guide RNAs were transferred to *Jinx* CD8+ T cells and HSCs by electroporation. While the ABE was not active in primary cells, 61-71% of *Unc13d* alleles were edited by CBE. Functional assays confirmed reestablished cytolytic activity of edited T cells. High-throughput sequencing-based CAST-Seq and rhAmp-Seq analysis to characterize CBE-associated off-target effects in *Jinx* mouse CD8+ T cells and HSCs revealed unexpected genotoxicity. We detected CBE-mediated chromosomal translocations as well as insertion/deletion mutations at both on- and off-target sites. The *Unc13d*-edited HSCs have been transplanted into conditioned *Jinx* mice to demonstrate functional restoration of lymphocyte cytotoxicity in the preclinical FHL3 model. The results of these *in vivo* experiments as well as the evaluation of off-target effects in *Jinx* mice transplanted with CBE-edited HSCs, will be presented.

1477 Non-Canonical NFKB Signaling Endows Suppressive Function through FOXP3-Dependent Regulatory T Cell Program

Yohei Sato, Erika Osada, Yoshinobu Manome

Jikei University, Tokyo, Japan

Regulatory T cells (Tregs) is playing a central role in controlling adaptive immune response in human and mice. FOXP3 is a master transcription factor for Treg differentiation and suppressive function. Nuclear factor 'κ-light-chain-enhancer' of activated B cells (NFKB) signal is an essential signaling pathway related to the cell proliferation, differentiation and apoptosis among different lineages across the species. To date, functional roles of the non-canonical NFKB signaling in Tregs have been mainly studied in the transgenic mice, however the biological role of the non-canonical NFKB signaling in human Tregs is not yet fully discovered. To understand the biological role of non-canonical NFKB signaling in human Tregs, Treg-like cell line (MT-2 cells) and human primary Tregs are genetically engineered by CRISPR/Cas9. Interestingly, NFKB2 knockout MT-2 cells showed the downregulation of FOXP3, not by the NFKB1 knockout. In addition, the mRNA expression of FOXP3-dependent molecules including CTLA-4, GITR and IKZF-2 were significantly reduced by NFKB2 knockout MT-2 cells. Similar to the MT-2 cells, NFKB2 knockout human Tregs showed the significant reduction in the FOXP3 expression. Furthermore, NFKB2 knockout human Tregs showed downregulation of FOXP3-dependent molecules including CTLA-4, GITR and IKZF-2 similar to the Treg-like cell line. In addition to the phenotypic changes, NFKB2 knockout Tregs showed a reduced suppressive function compared to the wild-type and NFKB1 knockout Tregs. Here, we have shown that non-canonical NFKB signaling maintained Treg-like phonotype and suppressive function in human Tregs through the FOXP3-dependent regulatory T cell programme.

1478 AAV Gene Therapy for Autosomal Dominant Optic Atrophy Caused by Mutation in the Opa1 Gene

Rachel M. Stupay[1], Alyna Cascone[1], Linas Padegimas[2], Paul T. Wille[1], Brian M. Kevany[3]

[1]Product Development, Abeona Therapeutics, Cleveland, OH,[2]Forge Biologics, Grove City, OH,[3]Vice President, Chief Technical Officer and Head of Research, Abeona Therapeutics, Cleveland, OH

Autosomal dominant optic atrophy (ADOA) is caused by mutations in the Opa1 gene. Opa1 is a dynamin-related GTPase that localizes to the mitochondrial membrane. Opa1 protein stabilizes the inner mitochondrial membrane and acts in mitochondrial fusion and inner membrane remodeling. Mutant phenotypes present with a progressive loss of retinal ganglion cells that results in optic nerve degeneration and legal blindness with a loss of visual acuity, optic disc pallor, and color vision deficits. Approximately 50% of pathogenic mutations result in a truncated protein due to mutations in the GTPase domain resulting in a dominant-negative effect. There are 8 different splice variants, with variant 1 (main variant) and 7 (E5B) being the most prevalent and consisting of the L-isoform and either the ΔS1 or both the ΔS1 and ΔS2 isoforms, respectively. Variant 5 lacks the L-isoform and only contains the ΔS1 isoform and is cleaved from the membrane and therefore soluble. Here we constructed an AAV-vectored gene

therapy for ADOA expressing normal human Opa1 and delivered with the AIM® library capsid AAV204. Expression of isoform variants 1, 5, and 7 were assessed in Opa1 knockout mouse embryonic fibroblasts (MEFs) with both un-tagged and Flag-tagged constructs. We further characterized Opa1 expression in both the wild-type (WT) and Opa1 heterozygous (HT) mouse retina 2 months post treatment with an intravitreal injection. Opa1 homozygous mice are embryonic lethal and therefore HT animals were used for Opa1 viral expression. Methods: AAV204 viral constructs were made for variants 1, 5 and 7 for both the un-tagged and Flag-tagged constructs. WT and Opa1 KO MEFs were transduced with all 6 constructs and analyzed 1-week post-transduction for RNA and protein expression. Next, 1 µL of 3.0×10^9 vg/µL AAV204-hOpa1 constructs were intravitreally injected into mouse retinas at 1 month of age and analyzed by RNA and protein expression at 2 months post-injection. Results: In cell culture, all 3 variants expressed both RNA and protein with each variant corresponding to the appropriate cleavage pattern on manual westerns for both the un-tagged and Flag-tagged constructs. Following transduction of the Flag-tagged construct in WT mice, variants 1 and 7 expressed protein, with variant 7 transcript only generating the L-isoform. However, there was no expression of variant 5 at either the RNA or protein levels. HT mice were thus transduced with only variants 1 and 7, with both expressing RNA and protein. Conclusions: These results suggest that AAV204-CBh-Opa1 expression is significant at both the RNA and protein levels both in vitro and in vivo. This indicates that intravitreal injection is an efficient route of administration for a gene therapy for Opa1 replacement in ADOA. There are ongoing studies to assess for long-term rescue of Opa1 in animals that were treated for 10 months with in vivo analysis for Optical Coherence Tomography, Electroretinogram, and Optokinetic Response in addition to RNA and protein expression analysis.

1479 Smartphone-Based Titration of Baculoviral and AAV Vectors

Thomas P. Quinn, Lily Lee, Mei Fong, Yi Zhao, Michael Haugwitz, Andrew Farmer

Takara Bio USA, San Jose, CA

Baculoviral expression systems are well-established in the manufacturing of diverse proteins, including viral vaccines and gene therapy vectors, such as AAV, in which yields can be as much as 10-fold higher than with traditional 293-based methods. The advantages of the baculoviral expression system include flexible product design, manufacturing speed and scalability, and inherent safety. Recombinant baculovirus is constructed by first cloning the gene of interest (GOI) into a transfer plasmid. Subsequently, this transfer plasmid is co-transfected with a linearized parental AcMNPV genome into insect cells where homologous recombination takes place to generate a recombinant baculovirus. Successful expression of a recombinant protein relies on knowing the infectious titer of the baculovirus preparation, as it permits calculation of the multiplicity of infection (MOI) which can influence the final expression level of the recombinant protein. Plaque assays, endpoint dilution assays, quantitative real-time polymerase chain reaction, and flow cytometry, have all been used to determine baculovirus titers. However, these methods are time-consuming and labor-intensive, with time to results ranging anywhere from two hours to four days. In this work, we present an iOS and Android-compatible smartphone application that analyzes a gp64-specific lateral flow assay and can deliver plaque-forming unit values (PFU/ml) in 10 minutes when a reference virus with a known infectious titer is used. The simplicity of the assay facilitates easy monitoring and optimization of baculoviral production processes to ensure consistency and confidence in downstream applications. The two-step assay consists of adding a small amount (20µl) of baculoviral supernatant to the lateral flow device followed by imaging and analysis of the results using a smartphone. Densitometric analysis of the observed bands is performed by the intuitive GoStix Plus software that compares the results to an automatically downloaded, lot-specific standard curve. The result is a GoStix Value (GV) that, like a plaque or qPCR assay, can be used to normalize virus stocks before being used for the expression of a recombinant protein. Beginning with the construction and transfection of a ZsGreen1 expressing baculoviral vector, we were able to detect baculovirus as early as 4 days post-transfection (P0). In addition, we were able to demonstrate that these tests can be used to screen viral clones (plaques) for titer after one round of amplification (P1). The tests demonstrated titer values within 3-fold of current titration methods with coefficients of variation of less than 15%. Furthermore, to add to the utility of these lateral flow-based tests, we were also able to demonstrate the ability to detect and quantify baculovirus-produced AAV particles using an AAV capsid-specific antibody. This method will be the focus of our work moving forward. In summary, this highly convenient, lateral-flow-based titration technology can quantify both baculoviral and AAV vector preparations in approximately 10 minutes, reduce expenses related to labor and materials, and accelerate baculoviral vector production and protein expression workflows.

1480 Multiple Cell Processing Applications Using the Counterflow Centrifugation Technology

Young J. Kim, Carl Dargitz, Pushpalatha Chaluvappa, Enoch Tsui, Norbert Hernandez

Thermo Fisher Scientific, Carlsbad, CA

Counterflow centrifugation technology utilizes cell separation based on their size and density. Here, we demonstrate flexibility of the technology to incorporate different cell processing methods, providing an opportunity for users to choose a method based on their specific cell therapy workflows. Currently there are several manual methods to isolate PBMCs from leukaphresis products but most of them are highly user-dependent and laborious. Our data demonstrate that the automated counterflow centrifugation technology using the CTS Rotea System can perform PBMC isolation methods in a highly reproducible and effective manner by comparing the performances of the counterflow centrifugation protocols and a density gradient manual method. The automated counterflow centrifugation methods included Ficoll, ACK lysis buffer, and red blood cell elutriation. Regardless of the processing methods, high percentage (>98%) of the leukocyte population was isolated with minimal loss in recovery and viability (Figure 1). In addition, cellular compositions and post-processing effects of the isolated cells were characterized and compared. In all, the data show effective and consistent PBMC isolation across the four methods and flexibility of the automated counterflow centrifugation

system to successfully integrate existing methods. This work can serve as basis for expanding cell processing applications by leveraging the existing technology.

Cell types	Gating strategy	Frequency (%) of cells				
Pre-processing	Ficoll	Manual Ficoll	Lysis	RBC Elutriation		
Leukocytes	CD45+	79.7	99.6	98.5	99.7	99.8

Adeno-associated virus (AAV)-mediated gene therapy (GT) has demonstrated transformative potential in treating genetic disorders, but off-target transgene expression remains an important safety issue. Encoded's next generation sequencing (NGS)-based functional screening and model-based sequence enrichment platform efficiently identifies regulatory elements (REs) from human genomic sequences to modulate transgene expression. Previously, we identified and validated 3'UTR elements that selectively reduced off-target liver expression to undetectable levels while maintaining central nervous system (CNS) expression in mice. We also applied our high-throughput screening method to achieve a specific transgene expression profile: selective de-targeting of dorsal root ganglion (DRG) expression, while maintaining CNS expression. We simultaneously tested >10,000 genomic REs and identified and validated top 3'UTR genomic sequences that achieved robust DRG de-targeting and maintained CNS expression in mice. Here, we used this large-scale functional data for predictive modeling to identify sequence features that contributed to DRG de-targeting and designed second-generation libraries (GEN2) to further improve performance. Using these GEN2 AAV libraries, we developed RE sequences that simultaneously de-target expression in DRG and liver, discovered novel candidate DRG de-targeting sequences, and achieved further improvement in de-targeting efficiency. Finally, multiplex GEN2 library screening in non-human primates (NHPs) showed conserved function across species for top de-targeting REs. In conclusion, we applied high-throughput functional and computational screening to efficiently discover, optimize, and validate multiple de-targeting REs to drive potency and specificity in cell types and organ systems, including DRG neurons and liver. These human genomic REs have the potential to improve gene therapy constructs and may enable optimized safety and efficacy profiles for patients through increased flexibility in GT modality, dose, and route of administration.

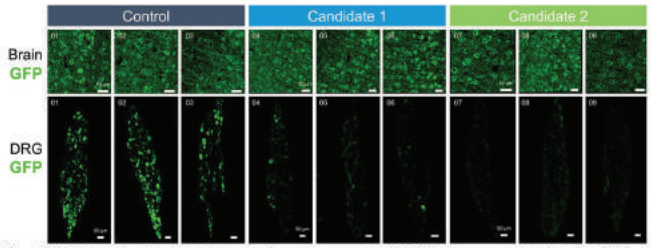

Figure 1. DRG de-targeting: Representative images of mouse samples stained for AAV transgene expression show that 3'UTR sequence elements substantially reduce off-target expression in the DRG, while maintaining CNS expression.

1482 Self-Complementary AAV Genome Orientation May Affect Overall Transgene Expression Efficiency

Frederick J. Ashby

College of Medicine, University of Florida, Gainesville, FL

Adeno-associated virus (AAV) gene-therapy has expanded prolifically in the past decade, with over 150 active clinical trials currently registered through the NIH database. While great progress has been made in novel capsid engineering, many of the same intrinsic limitations of AAV remain, particularly the limited transduction efficiency, immunological interference and a limited genomic capacity of ~4.7kbp. Previous research has demonstrated that transduction efficiency can be improved by employing modifications to the inverted-terminal-repeats (ITRs) of AAV, forcing it to package as a self-complementary form (scAAV) instead of its typical single-stranded form, thus bypassing second-strand synthesis during vector transduction. This is done by modifying the terminal-resolution-site (TRS) and the D-sequence on one ITR (ΔITR), but not the other, disallowing hairpin resolution but maintaining packaging viability. This intrinsically reduces the packaging capacity by half, but remains an option for many monogenic treatment strategies. Interestingly, there are no studies found by the author that demonstrate if there are any differences between placing the ΔITR is upstream of the transgene (ΔITR-up) or downstream of the transgene (ΔITR-down). In this experiment, an AAV2-ITR vector

plasmid with an enhanced green-fluorescence protein (EGFP) driven by a chicken-β-actin promoter (CBAp) was packaged ΔITR-up, and again with ΔITR-down (Figure 1) using similar packaging (HEK293, triple-plasmid transfection) and purification methods (Iodixanol & dialysis spin columns). The same process was setup for AAV3-ITR carrying the same genome payload. Huh7 cells were transfected with equivalent MOI (3000 vg/cell) with and after 72 hours demonstrated 2-3 fold increase in transgene expression, as measured by fluorescence, in AAV2-ΔITR-up compared to AAV2-ΔITR-down ($p<0.001$). This same experiment with AAV3 demonstrated 4-5 fold increase in transgene expression for AAV3-ΔITR-up compared to AAV3-ΔITR-down ($p<0.001$), thus indicating this may be a characteristic across multiple serotype ITRs. Representative images are shown in Figure 2. This was followed up with RNA extraction and quantification by RT-qPCR, which demonstrated commensurate increase in RNA levels for ΔITR-up (AAV2 & AAV3) compared to ΔITR-down. Ultimately, this suggests transgene orientation relative the ΔITR in scAAV may not be an inert factor, at least *in vitro*, and any experiments comparing self-complementary vectors should use scAAV in the same orientation for all experimental and control groups. It is yet unknown if this effect is transient or persistent regarding long-term transgene expression, but regardless this may have clinical relevance for overall vector treatment efficiency and scAAV genome design if the superiority of scAAV-ΔITR-up over scAAV-ΔITR-down also occurs *in vivo*.

1483 Safety and Efficacy of AAV-Mediated Homology-Independent Targeted Integration at the 3 Prime Mouse Albumin Locus

Federica Esposito[1], Fabio Dell'Aquila[1], Rita Ferla[1], Manel Llado[1], Paula Sureda Horrach[1], Stefano Auricchio[1], Margherita Dell'Anno[1], Edoardo Nusco[1], Manuel Rhiel[2], Toni Cathomen[3], Alberto Auricchio[1,4]

[1]Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli (Naples), Italy,[2]University Medical Center Freiburg, Freiburg, Germany,[3]Medical Center - University of Freiburg, Freiburg, Germany,[4]Department of Advanced Biomedical Sciences, Federico II University, Naples, Italy

Liver-directed gene transfer with adeno-associated viral (AAV) vectors is being considered for therapy of both liver and systemic diseases. Despite their great therapeutic potential, AAV vectors are predominantly non-integrative, preventing their application to newborn liver which is the preferred target for early-onset inborn errors of metabolism.To overcome this limitation, we developed AAV-mediated homology-independent targeted integration (HITI) by CRISPR/Cas9 to integrate a therapeutic transgene at the 3' end of mouse Albumin which is highly expressed in hepatocytes. We show the efficacy of our system in a mouse model of Mucopolysaccharidosis type VI (MPSVI) lacking the lysosomal enzyme arylsulfatase B (ARSB). Neonatal AAV-HITI delivered at the highest dose tested, leads to supra-physiological and stable levels of secretion of the serum active ARSB from the liver up to 1 year of age. Our data suggest safety of AAV-HITI with unaltered levels of secreted Albumin and no evidence of hepatocellular carcinoma development at this stage. We are currently conducting off-target analysis and a dose-response study in newborn MPVI mice with doses lower than those used in the initial experiments.Overall, our data support AAV-HITI as a potential therapeutic option for the treatment of those conditions which involve the liver as target tissue and that require an early intervention.

1484 Rescuing Haploinsufficient Expression of *ADNP* in Human and Mouse Cell Lines Using CRISPR Activation

Katherine L. Lucot[1], Renee Napoliello[1], Julian Halmai[2], David J. Segal[3], Jill L. Silverman[4], Kyle D. Fink[5]

[1]Neurology, UC Davis School of Medicine, Sacramento, CA,[2]UC Davis, Sacramento, CA,[3]UC Davis Genome Center, Davis, CA,[4]Psychiatry and Behavioral Sciences, UC Davis School of Medicine, Sacramento, CA,[5]Neurology, UC Davis, Sacramento, CA

Introduction: *Activity-dependent neuroprotective protein* (*ADNP*) Syndrome, is a rare neurological disorder caused by a pathogenic mutation in one copy of the *ADNP* gene. These mutations are *de novo* and result in a loss of function of the mutated copy of the gene causing a haploinsufficency. Clinically, patients with *ADNP*Syndrome have autism and comorbidly present with mild to severe intellectual disability, brain abnormalities (e.g., sleep disorders and seizures), organ system complications (e.g., gastrointestial and cardiovascular defects), skeletal abnormalities, and dysmorphic features such as eyelid eversion, broad nasal bridge, and thin upper lip. *ADNP* plays a critical role in brain development, cognition, and motor function. While CP201 (NAP) and ketamine have both been tested for off-label

use and/or are currently in clincial trials, methods to fully restore a healthy phenotype in these children, especially during this critical time point, has yet to be fully explored. Herein, we investigate the utility of a CRISPR activation (CRISPRa) system in an AAV-ready construct, paired with a single guide RNA (gRNA), to target and increase expression of endogenous *ADNP* in human and mouse cell lines. **Methods:** Human gRNAs, targeting the promoter of *ADNP*, were chosen from either the Gilbert, *et al*.dataset (n = 10) or designed using CHOPCHOP (n = 10). HEK293 cells were maintained and triple transfected with intein-containing vectors, each containing one terminus of dCas9 fused to either the activating domains mini-VPR (VP64-p65-Rta) or MS2-P65-HSF1 (MPH), and a gRNA. The potency of each gRNA to increase *ADNP*transcription was measured using RT-qPCR. The five most active gRNAs were then tested in a more cell and disease contextual model - human iPSCs were created carrying two common *ADNP* mutations (p.V180fs and p.Y719X) and differentiated into neural stem cells (NSCs). Concurrently, the same dCas9 system was evaluated for *Adnp* using mouse gRNAs (n = 15) in Neuro 2A cells. **Results:** 20 gRNAs were screened in the HEK293 cells, with gRNA C9 showing the greatest increase in transcription ($p < 0.0087$). The five most activating guides from the HEK293 experiments (C4, C9, C10, W5, W9) were then tested in the differentiated NSCs. C4 and W9 both showed a significant increase ($p < 0.015$ and $p < 0.0001$) in relative gene expression; 1.5- and 2-fold respectively. These guides were then multiplexed and gene expression evaluated in NSCs. Of the mouse gRNAs, C3 showed nearly a two-fold higher gene expression ($p < 0.0392$). **Conclusion and Future Directions:**A split dCas9 system with activation domains is a promising tool for altering the epigenetic state and increasing endogenous *ADNP* expression. The lead mouse guide (C3) will be packaged with the activator domains into AAV particles, which will allow for us to test the CRISPRa system *in vivo* in *ADNP* mouse models. The lead human gRNA (W9) is currently beging evaluated in engineered iPSCs differentiated into NSCs, containing common patient mutations, to evaluate rescue of cellular function.

1485 Intercellular Zinc Finger Protein Delivery for Cross-Corrective Epigenetic Regulation in the CNS

Gillian Houlihan, Qi Yu, Kimberly Marlen, David Ojala, Sebastian Arangundy, Jennifer Zeitler, Amy Pooler, Bryan Zeitler

Sangamo Therapeutics, Inc., Richmond, CA

We are developing zinc finger transcriptional regulators (ZF-TRs) to create genomic medicines for the treatment of neurological diseases. The potency, tunability, high specificity and compact size of ZF-TRs has been leveraged to successfully modulate the expression of gene targets involved in an array of neurodegenerative and neurodevelopmental disorders. However, widespread brain delivery of therapeutic transgenes remains challenging due to the limited CNS transduction efficiencies of currently available AAV capsids. Cellular secretion of ZF-TRs from AAV-transduced cells and uptake to neighboring cells could provide a new way to achieve broader ZF-TR mediated epigenetic regulation in target CNS cells by cross-correcting non-transduced cells. Here we have developed enhanced ZF-TR architectures capable of protein secretion using the secretory pathway. A secreted luciferase reporter assay using a ZF targeting an endogenous gene fused to the KRAB repressor domain (ZF-R) revealed that the addition of a signal peptide was insufficient to enable cellular secretion of ZF-R protein. However, protein engineering strategies led to >30-fold increase in the levels of secreted protein when fused to different signal peptides. Furthermore, several mutations further increased ZF-R secretion and maintained gene repression activity in donor cells. ZF-R protein secretion was demonstrated in different cell types including mouse cortical neurons and astrocytes, with >250-fold increase in the level of ZF-R secretion observed in astrocytes. Addition of a purified recombinant ZF-KRAB protein to a neuroblastoma cell line demonstrated that ZF-R proteins have intrinsic cell-penetrating ability and maintain target gene regulation activity in recipient cells. Ongoing work will focus on assays to measure cellular secretion and uptake in relevant cell types. Intercellular delivery in the CNS could significantly increase the number of cells exposed to ZF-TRs, thus increasing the potential therapeutic benefit for a range of CNS disorders.

1486 Competition of Co-Transduced CARs for Cellular Resources in Dual-Targeting CAR T Cells

Catalina Barceló[1], Alba Rodriguez-Garcia[1], Mireia Bachiller[1], Marta Giménez-Alejandre[1], Álvaro Urbano-Ispizua[2], Sònia Guedán[1]

A major limitation for Chimeric Antigen Receptor (CAR) T cell therapy is tumor escape mediated by antigen loss. A possible strategy to mitigate this is to use CAR-T cells targeting multiple antigens, although the optimal strategy to develop multi-targeting CAR-T cells is yet to be defined. Here, we tested co-transduction of lentiviral vectors expressing two different CARs to generate dual-targeting CAR-T cells. One peculiarity of this strategy is that the final CAR-T cell product consists of three different CAR populations, including a double positive population expressing both CARs in the same T cell and two single-targeting populations for each CAR alone. Considering that cellular resources are limited, we hypothesized that co-expression of two CARs in the same T cell could compete to use the transcription and translational machinery. This could result in an impaired expression of one or the two CARs on the T cell surface and an imbalance in the percentages of the three populations. To verify this hypothesis, we transduced T cells with different combinations of CAR constructs, including ARI-0001, targeting CD19, and ARI-0002, targeting BCMA (both 4-1BB-based CARs developed at Hospital Clínic de Barcelona-IDIBAPS), and CD28-based CARs targeting HER2 or mesothelin. We observed that, in the majority of CAR combinations, when co-transducing two lentiviral vectors, one or both CARs were expressed at lower levels on the T cell membrane than when transduced individually. Impaired and/or imbalanced CAR expression in dual CAR-T cells was exacerbated when increasing multiplicities of infection (MOI) were used, indicating a greater competition for CAR expression as saturation of cellular machinery approached. Of note, some CARs maintained its protein expression in co-transduction regardless of the combination used and therefore competed more efficiently for limited cellular resources. CAR competition was assessed at DNA, RNA and protein level. CARs were equally integrated in the genome when they were

transduced as single CARs as compared to co-transduced with another CAR. By contrast, CAR competition showed to start at the RNA level, since lower RNA levels were detected in co-transduction when compared to single transduction, revealing that transcriptional machinery is more sensitive to gene expression burden. Finally, we demonstrated that the use of different MOIs for each co-transduced CAR or the screening of codon-optimized CAR versions are possible strategies to generate dual-targeting CAR T-cells containing balanced populations of each CAR when using the co-transduction technique. These results are of great importance for the application of dual CAR-T cells in the clinic, suggesting that the amounts of lentivirus used for the manufacturing of T cells expressing two transgenes must be carefully controlled in order to not saturate cellular resources and conserve endogenous expression intact. Our results could be applied to other strategies currently being explored to improve efficacy of CAR-T cells, for instance incorporating other therapeutic transgenes instead of a second CAR.

1487 Kinetic Analyses Reveal Very Early CpG-Specific Antagonism to AAV-Mediated Transgene Expression: Implications for TLR9 Stimulatory Effects Prior to Effector T Cell Activation Following Gene Transfer

Justin Glenn[1], Henos Negash[1], Randolph Qian[1], Ye Liu[1], Joseph T. Bruder[2], Olivier F. Danos[2], Subha Karumuthil-Melethil[3]

[1]Regenxbio, Rockville, MD,[2]REGENXBIO2, Rockville, MD,[3]REGENXBIO2, Germantown, MD

The success of AAV-mediated gene therapy relies on maintenance of sufficient transgene expression to provide therapeutic benefit. A significant obstacle to transgene expression are antagonistic, inflammatory innate and adaptive immune responses. CpG motif-mediated TLR9 stimulation is thought to suppress transgene expression by: (1) early (hours to days) innate activation of plasmacytoid dendritic cells (pDCs) and conventional dendritic cells (cDCs) which collude to (2) activate antigen-specific T cells (days-weeks) that extinguish transgene expression from transduced cells. Our investigations into the kinetics of transgene expression in the setting of CpG depletion led us to the present unreported finding that CpG-dependent differences in transgene expression occurred as early as 24 hours post-vector administration, a timepoint well ahead of effector T cell action. In this study, two CAG-promoter driven, anti-plasma kallikrein antibody cassettes (α-pKal) packaged in AAV9 were generated: the α-pKal transgene sequence was left either CpG retained (CpG+) or CpG depleted (CpG-). Either vector was then intravenously administered to Balb/C mice at a dose of $1x10^{13}$ vg/kg. ELISA analyses for α-pKal showed 2-3-fold increases in protein secreted into serum from mice that received CpG- vector compared to those receiving CpG+ vector at 24- and 48-hours post-vector administration. This trend in transgene expression difference continued to the study terminus (day 30). Transgene transcriptional analyses largely showed no differences in α-pKal mRNA levels in the liver, heart, and gastrocnemius muscle. Vector abundance was also measured in these tissues and results do not support observed α-pKal protein expression differences between the two groups. Immunological evaluations confirm that CpG+ vector-injected mice exhibit higher levels of very early canonical TLR9-induced inflammatory genes, including IFN-β (up to 6-fold) and CCL2 (up to 2-fold), compared to CpG- vector-injected mice. However, IL-6 exhibited a differential tissue-specific induction pattern: CpG+ vector-receiving mice exhibited up to 2-fold induction of IL-6 in the liver, but 6-7-fold reduction in other tissues. Since early TLR9 stimulation mobilizes innate immune cells, we did flow cytometry to measure various cell frequencies and repeatedly observed that a PDCA-$1^{lo/-}$CD11b^{+} CD11$c^{+/-}$ MHC-$II^{hi/lo}$ pDC-like cell population was significantly more abundant in CpG+ vector-injected mice compared to CpG-vector-injected mice. Studies are on-going to evaluate early T cell activation and effector function of the identified pDC-like cell population. In summary, TLR9-mediated antagonism of transgene expression may occur prior to effector T cell action and warrants further investigation into mechanisms that operate independently and/or support eventual T cell targeting of transduced cells.

1488 Development of an Allogeneic FAP-CAR iNKT Cell Therapy to Modulate the Immunosuppressive Stroma and Improves Anti-Tumor Immunity Against Non-Small Cell Lung Carcinoma

Shannon Boi[1], Martyna Popis[2], Magda Niedzielska[2], Reed Masakayan[1], Efrat Altman-Sharoni[2], Vignesh Venkatraman[3], Priyadarshini Iyer[4], Sapana Pokharel[1], Olivier Le Tonqueze[1], Justin Keith[4], Barbara Kalinowska[4], Bishnu Joshi[4], Rachel Smith[1], Moira Pinzan Rossi[2], Deborah Wright[2], Paul Ibbett[2], Olga Ignatovich[3], Dhan Chand[4], Eleni Chantzoura[2], Xavier Michelet[1], Marc A. Van Dijk[2]

[1]MiNK Therapeutics, Lexington, MA,[2]MiNK Therapeutics, Cambridge, United Kingdom,[3]Agenus, Cambridge, United Kingdom,[4]Agenus, Lexington, MA

Lung cancers are one of the leading causes of cancer-associated deaths worldwide in men and women, with non-small cell lung cancer (NSCLC) accounting for ~82% of diagnoses. These cancers are highly immunosuppressive and are often refractory to current immunotherapies. Given the outstanding success of CAR T cell therapies in hematological cancers, there has been a push towards generating CAR T cell therapies for other cancer types. However, CAR T cell therapies in solid tumors, such as NSCLC, have been underwhelming to date—highlighting the need for novel therapeutic approaches for patients. The lack of benefit from conventional CAR T therapy in solid tumors is mainly due to the inability to infiltrate the tumor and survive the hostile tumor microenvironment (TME). Cancer-associated fibroblasts (CAFs) in the tumor microenvironment are a major driver of resistance, enhance tumor cell proliferation and endogenous immune suppression. *Therefore, a successful CAR therapy should ideally promote i.) infiltration of CAR-expressing cells into the tumor, ii.) direct cytotoxicity against the tumor, and iii.) reshape the immunosuppressive TME*. MiNK Therapeutics is developing novel allogeneic invariant natural killer T cells (or iNKTs) to target solid tumors and TME. iNKT cells uniquely designed for tumor killing via multiple mechanisms. They can directly kill tumor cells by recognition of lipid tumor antigens and stress ligands. They can also reshape the

TME by secreting IFN-γ, which can enhance the recruitment and activation of CD8+ T cells and NK cells. iNKT cells can additionally improve dendritic cell activation, selectively kill M2 suppressive macrophages, and enhance anti-tumor activity of exhausted CD8+ T cells. More importantly, these cells naturally infiltrate into tissues such as the lung and liver, making them an ideal candidate for CAR therapies against solid tumors, such as NSCLC. To overcome the immunosuppression and enhance tumor control we developed a chimeric antigen receptor (CAR), which targets fibroblast activation protein (FAP)—a surface marker overexpressed on CAFs during tumor progression. MiNK-215 is an engineered iNKT adoptive cell therapy in which iNKTs express FAP-CAR scFv and secrete IL-15 to increase cell persistence. Functional characterization demonstrated that MiNK-215 specifically recognizes and kills FAP-expressing cells and promotes *in vivo* tumor control in a mouse xenograft solid tumor model. Furthermore, activated iNKT cells harboring the CAR molecule display a proinflammatory phenotype *in vitro* and *in vivo*. To address the challenge of the immunosuppression exhibited in lung tissue, we developed a NSCLC xenograft model in which orthotopic development of the tumor triggers the settlement of murine FAP-expressing CAFs. Using a mouse surrogate of MiNK-215 targeting CAFs and not the tumor, we demonstrated that the reshaping and destruction of the stroma impairs tumor progression in the lungs and improves overall survival by mediating activation and tumor infiltration of tumor-specific CD8+ T cells. Taken together, we demonstrate that targeting FAP-expressing CAFs with MiNK-215 cell therapy has the capability to promote a productive therapeutic response and expand survival in solid tumor models. Furthermore, it represents an attractive off-the-shelf allogenic cell therapy in a broad range of solid tumor cancers.

1490 Application of Baculovirus Vectors in the Prevention of Gastrointestinal Diseases

Baculoviruses are rod-shaped viruses with a circular double-stranded DNA genome of 80-180 kbp, which infect arthropods and efficiently transduce non-dividing mammalian cells *in vitro* and *in vivo*. Recombinant baculovirus virions have been used for different purposes in mammals, such as gene therapy and the development of vaccines. We investigate whether baculoviruses can be used in the prevention of gastrointestinal diseases. In humans, infection with *Helicobacter pylori* is the leading cause of gastritis, peptic ulcer, and stomach cancer (adenocarcinoma and mucosa-associated lymphoid tissue lymphoma). Despite the seriousness of the diseases, there is currently no approved *H. pylor*i vaccine. In this work, we evaluated whether a recombinant baculovirus carrying a hybrid transgene can induce an immune response against *H. pylor*i. The gene called Thp1 codes for nine epitopes of the proteins of the *H. pylori*: carbonic anhydrase, urease B subunit, gamma-glutamyl transpeptidase, Lpp20, Cag7, and CagL. The expression of the multi-epitope fusion protein was verified in HeLa cells transduced with the recombinant baculovirus Bac-Thp1. Thus, mice were inoculated by different routes with the Bac-Thp1 baculovirus. We identified a strong B cell response. Serum IgGs specific for *H. pylori* were more abundant when the Bac-Thp1 baculovirus was administered intramuscularly, while the production of specific IgAs for the bacteria in feces was higher when the vaccine was inoculated intragastrically. Noteworthy, the B cell responses lasted for several months. Baculovirus-mediated expression of antigens may be a good strategy as recombinant vaccines for various gastrointestinal diseases.

1491 Novel CGT Viral Vector Lysis Kit for AAV Enables a Standardized AAV Workflow from Cell Lysate to Absolute and Precise Quantification of Viral Titers

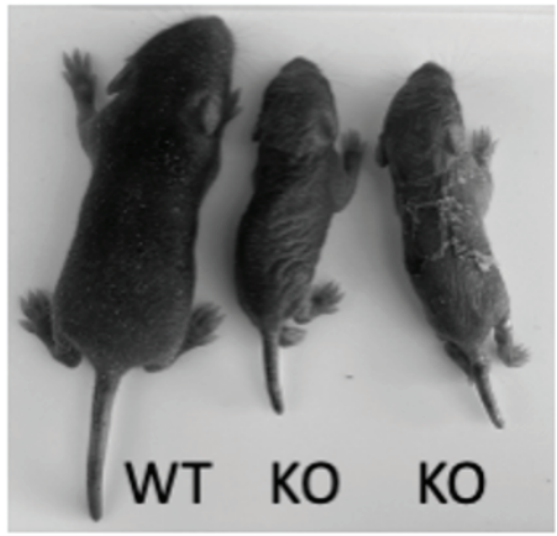
Domenica Martorana[1], Daniel Lofgren[2]
[1]R&D, QIAGEN GmbH, Hilden, Germany,[2]QIAGEN AB, Kista, Sweden

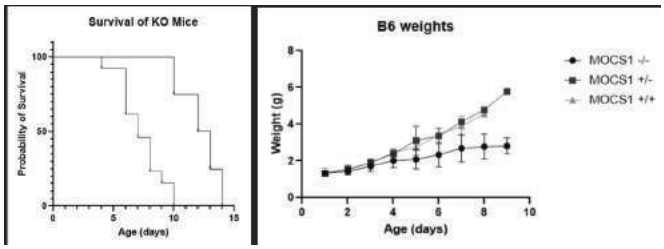
Cell and gene therapies seek to target previously untreatable diseases at their source using individualized treatments. However, developing safe and effective cell and gene therapies requires strict monitoring at all stages of the development process. Adeno-associated virus (AAV) has turned into a primary modality for efficient gene therapy applications. The process of generation and purification of the viral vectors require precise quality control to enable safe and reliable dosing during clinical studies or patient care. The ability to accurately and reproducibly quantify vector titers is essential for safe and effective AAV-based gene therapies. The AAV genome is a key component for vector quantification. While several quantification assays are available, here we outline a standardized processing and quantification workflow compatible with many AAV preparations of different purities. We show that an optimized capsid lysis procedure together with an increased target accessibility allows for a robust genome titration throughout the whole viral vector manufacturing process using PCR. qPCR is a widely used method for AAV quantification due to its sensitivity and ease of use. Nevertheless, well-characterized DNA standards and assays are needed for accurate quantification. Digital PCR enables absolute quantification with unprecedented precision and a higher tolerance towards inhibitors without the need for any standards. Additionally, more than one region of interest can be quantified at once leading to further information on genome intactness. Besides AAV genome quantification, the determination of potential impurities is crucial. Manufacturers of biologics use different approaches to show, for example, low residual host cell DNA (HCD) or Mycoplasma contaminants throughout the production process and final substance. Levels of HCD must not exceed levels established by regulatory authorities, hence, HCD monitoring is an important step in the process of manufacturing since potential carryover poses a safety concern. Here we layout a dPCR-based streamlined workflow for impurity quantification with increased precision and robustness without the need for long and tedious sample preparation.

1492 AAV Compatible Recombinant MOCS1 Gene Addition Therapy Restores Molybdenum Cofactor Synthesis and Sulfite Oxidase Enzymatic Function

Claire Shamber[1], Edwin Alyea[1], Albert Misko[2], Guenter Schwarz[3], Casey A. Maguire[4], Patricia L. Musolino[1]
[1]Neurology, Massachusetts General Hostpial, Boston, MA,[2]Massachusetts General Hospital, Boston, MA,[3]Institute of Biochemistry Department of Chemistry & Center for Molecular Medicine Cologne University, Cologne, Germany,[4]The Massachusetts General Hospital, Charlestown, MA

Objective: To develop a gene addition in vivo therapy for Molybdenum Cofactor type A using a construct that recapitulates the complex expression of the endogenous MOCS1 gene. Background: Molybdenum Cofactor Deficiency (MoCD) is a devastating genetic, neurodegenerative condition of the neonatal period characterized by encephalopathy, severe brain atrophy and neurological disability and early childhood death. MoCD is estimated to affect one in 200,000 newborns globally and the median survival rate is 3 years. MoCD Type A stems from mutations in the highly conserved bicistronic MOCS1 gene that produces proteins MOCS1A and MOCS1B. Loss of enzyme activity abolishes production of molybdenum cofactor and inactivates molybdenum cofactor dependent enzymes. Among these enzyme deficiencies, the loss of sulfite oxidase, which normally functions to metabolize toxic sulfite into non-toxic sulfate, is necessary and sufficient to cause the neurodegenerative phenotype of MoCD. Accordingly, the clinical, radiographic, and pathological features of MoCD are identical to those in isolated sulfite oxidase deficiency (ISOD). Current available treatments are not well tolerated or fail to prevent disease progression. Methods: We designed an optimized AAV compatible recombinant version of the endogenous MOCS1 gene to restore enzyme activity. In vitro validation of MOCS1 expression and restoration of sulfite oxidation was performed by transfection of WT and MOCS1 knockout HEK293 cells. Expression of both MOCS1A and MOCS1B was measured by western blot and downstream enzymatic activity by metabolite quantification. We compare survival, behavioral, tissue metabolism and histological characteristics of the Mocs1 knock out mouse with WT and Mocs1 heterozygote. Biodistribution and early efficacy studies were performed at 7 days following P0 retroorbital AAV-rMOCS1 injections. Results Our designed rMOCS1 construct properly expressed both MOCS1A and MOCS1B and successfully restored sulfite oxidase (SUOX) enzymatic activity in MOCS1 knockout HEK293 cells. The established Mocs1 KO mouse showed severe phenotypic differences including nephrolithiasis, hyperkeratosis , severe progressive spasticity, overall stunted growth and early death averaging at day 7. Early biodistribution studies confirmed liver expression of MOCS1A and MOCS1B 5 days after P0 injection of AAV-rMOCS1.





Conclusions Our rMOCS1 construct shows proper expression of the MOCS1 bicistronic gene and restoration of enzyme activity in vitro. The Mocs1 mouse model recapitulates survival and severe neurological phenotype seen in patients. Systemic AAV-mediated gene delivery of our rMOCS1 construct could restore sulfite oxidase deficiency and prevent neurodegeneration.

1493 Inter-Nuclear Trafficking Improves Potency of Gene Therapy Cargoes in Skeletal Muscle

Kiril Poukalov, Eric T. Wang

Molecular Genetics and Microbiology, University of Florida, Gainesville, FL

Gene editing and other DNA targeting gene therapy approaches have shown promise in treating animal models of muscle disease despite overall low editing efficiencies and poor intracellular distribution of nuclear-targeted cargos. The activity of gene therapy cargoes is influenced by the extent of spread between myonuclear domains, from transduced to non-transduced domains. Failure to spread results in accumulation of cargoes in transduced nuclei, limiting treatment effects to small regions of myofibers and reducing overall potency. Here, we developed a system using a combination of nuclear localization signals (NLS) and nuclear export signals (NES) to facilitate trafficking of gene therapy cargoes between nuclei, preventing local accumulation and improving distribution. Trafficking exposes more non-transduced nuclei to cargoes, enhancing the overall treatment effect on the myofiber. Combinations of NLSs and NESs tagged to GFP were screened in C2C12 myotubes to observe overall localization patterns and identify candidates for testing in myofibers. AAV constructs were generated that express GFP, saCas9, or dsaCas9 tagged with selected NLS/NES combinations and delivered systemically to adult wild-type and diseased mice. Myofibers were isolated from treated mice to observe localization of cargoes and treatment effects relative to transduced nuclei, and compared to the commonly used 2xSV40 NLS tag. Ai14 Cre reporter mice treated with AAV expressing Cas9 with an optimized NLS/NES combination targeted to *loxP* sites showed increased editing efficiency and improved intracellular distribution of Cas9 compared to 2xSV40 NLS-tagged Cas9. HSA^{LR} mice (a model for myotonic dystrophy type 1) treated with AAV expressing repeat-targeted dCas9 with the NLS/NES combination showed greater reduction of CUG RNA foci in regions of the myofiber farther from transduced nuclei as compared to 2xSV40 NLS-tagged dCas9. This study demonstrates that nucleo-cytoplasmic shuttling of nuclear-targeted gene therapies can increase potency by improving intracellular distribution and relieving accumulation within transduced nuclei. This strategy has the potential to improve potency of all gene editing and DNA-targeted gene therapies in skeletal muscle and other multinucleated tissues.

1494 Developing Novel Strategies to Reduce Immunogenicity of AAV Vector

Winston Colon-Moran, Alan Baer, Nirjal Bhattarai

Gene Transfer and Immunogenicity Branch, FDA, Silver Spring, MD

Host immune responses against viral vector present significant challenge during viral vector-based gene therapies. Novel strategies to dampen or evade host immune responses against viral vector can improve the safety and efficacy of gene therapies. Previously, we demonstrated that expression of a small immunomodulatory peptide derived from the hepatitis C virus (HCV) NS5A protein by AAV vector reduced T cell activation (TCA) and recall T cell response against AAV *in vitro*. One of the limitations of this strategy is it requires constitutive expression of immunomodulatory peptide by AAV vector, which may not be desired in all AAV vector-based gene therapy. In the current study, we sought to identity a strategy to reduce TCA via mechanism that does not require constitutive expression of immunomodulatory factor by AAV vector. Previous studies have identified a role for hepatitis B virus (HBV) e antigen (HBeAg) and the surface antigen (HBsAg) in modulating human immune responses by mechanisms that do not require intracellular expression. We hypothesized that identification of immunomodulatory motif(s) of these proteins and incorporation of these motif(s) in AAV capsid may result in immunomodulatory AAV vector. To test this hypothesis, we treated human T cells with recombinant HBeAg or HBsAg and assessed for TCA. HBeAg but not HBsAg inhibited TCA in a dose-dependent manner. To identify immunomodulatory motif(s), four 40mer peptides (P1-P4) representing entire HBeAg sequence were synthesized. Human T cells treated with peptide P1 derived from the N-terminus of HBeAg significantly inhibited TCA. Current studies are underway to further map immunomodulatory region within the HBeAg. Once immunomodulatory region is identified, we plan to incorporate HBeAg-derived immunomodulatory peptide in the AAV capsid with goal to dampen TCA during AAV gene therapy.

1495 Clinical Proof-of-Concept of AAV Gene Therapy Efficacy in Adrenomyeloneuropathy (AMN) Mice at Time of Symptoms

Yasemin Özgür Günes[1], Catherine Le Stunff[1], Pierre Bougnères[2]

[1]INSERM, Le Kremlin-Bicrêtre, France,[2]Therapy Design Consulting, Vincennes, France

Closely mimicking human AMN, Abcd1 KO mice do not show disturbed motor balance before late adulthood. Indeed, around 16-18 months, many Abcd1 KO mice shown abnormal motor balance, but no myelin lesions. We previously reported the successful prevention of neurological signs of AMN by injecting AAV9 MAG-hABCD1-HA vector intravenously (IV) into 10-d mice (Özgür Günes, HGT, 2022). These experiments opened the way for early prevention of AMN, which will only be feasible in patients who will be screened at neonatal age. On the other side, there was yet no clinical demonstration in Abcd1 KO mouse of the efficacy of gene therapy on AMN symptoms once they have already emerged. To test if gene therapy could reverse or stabilize AMN symptoms, we treated 17-month old Abcd1 KO mice with IV (1E14 vg/kg) or intra-cisterna magna (ICM) (1.5E13 vg/kg) injection of the AAV9 MAG-hABCD1-HA vector. IV injections did

not improve motor balance of the diseased mice (negligible crossing of the blood-brain-barrier by vector) and did not transduced spinal cord oligodendrocytes.In contrast, ICM injections induced an improvement of motor balance already at 3 weeks post-injection then at 3 months. **Table**: Latency to fall (seconds) at rotarod tests in vector-treated (AAV), untreated (UT), wild-type (WT) mice (mean ± sd). [a] intra-group comparison (P-value ≤0.002) at 3 weeks and 3 months versus baseline, paired t-test. [b] inter-group non-parametric comparison of AAV vs UT mice P≤0.01.

	AAV (17)	UT (8)	WT (7)
Baseline	179 ± 58	174 ± 29	259 ± 33
After 3 weeks	243 ± 50[a,b]	196 ± 44	233 ± 17
After 3 months	233 ± 52[a,b]	183 ± 38	214 ± 50

These results are currently seeking confirmation in larger groups of mice. Three months post ICM injection of vector, immunofluorescence showed abundant transduction of white matter oligodendrocytes in spinal cord at cervical and lumbar levels. Neither neurons nor astrocytes expressed the transgene. **Temporary conclusion**: AAV9 equipped with MAG promoter relieves mouse AMN axonopathy through the only transduction of spinal cord oligodendrocytes. The unexpected rapid improvement of clinical signs suggests that AMN axonopathy is still largely functional and reversible in 17 month-old mice.

1496 Benchmarking NGS Integration Site Analysis Methods in Support of Long-Term Safety Monitoring of Cell and Gene Therapy Products

Andrea O'Hara[1], Eliza Small[2], Laure Turner[3], Haythem Latif[1], Chris Mozdzierz[1], Ginger Zhou[4]

[1]Azenta Life Sciences, Burlington, MA,[2]Azenta Life Sciences, Wilmette, IL,[3]Genewiz From Azenta Life Sciences, South Plainfield, NJ,[4]Genewiz, Inc./Brooks, South Plainfield, NJ

The FDA Guidance to Industry on Long Term Follow-Up (LTFU) After Administration of Human Gene Therapy Products states the importance of longitudinal testing of gene products introduced into human subjects. Depending on the delivery mechanism, the therapeutic gene product may or may not integrate into the genome. Of particular interest are gene-product integrations near proto-oncogenes which might lead to malignancies. The FDA LTFU guidance states that recipients of an integrating gene therapy modality should be tracked for 15 years, while those receiving a non-integrating therapy modality should be tracked for 5 years. Therefore, advanced analytical methods are needed to identify, quantify, and track integration events across the genome. Here, we provide a comprehensive evaluation of methods leveraging next-generation sequencing approaches for genome-wide analysis of lentiviral integration events. Our analysis employed well-characterized standards consisting of varying copy number and known integration sites. The approaches we characterized can be bucketed into two major groups: PCR amplification approaches and target capture-based approaches. All methods detected true positives with strong correlation to theoretical integration site dosage levels down to 1% allele frequency. Comparatively, PCR amplification-based approaches have lower data requirement per sample suggesting higher sensitivity, greater molecular capture, and lower limit of detection compared with target enrichment-based approaches. Target enrichment-based approaches can afford the flexibility to capture the integrated vector, which is of interest for characterizing partial integration events. While all methodologies performed well in our study, the choice of assay (or assays) for testing will depend on numerous factors including but not limited to the viral vector system and construct and starting material availability.

1497 Method for Identification and Characterization of Sites of Homology Directed Strand Cross-Over Using rAAV Integration Vectors

Sarah Potts[1], Jaime Prout[1], Alicia Palladino[1], Katherine Gall[1], Miranda Rubin[2], Donald Evan Selby[3], Nathanael Bourgeois-Tchir[1], John Thompson[4], Jason B. Wright[5]

[1]Homology Medicines, Bedford, MA,[2]Homology Medicines, Inc., Berlin, MA,[3]Homology Medicines - Bedford, MA, Bedford, MA,[4]Homology Medicines, Inc., Bedford, MA,[5]Homology Medicines Inc., Bedford, MA

Homology-directed repair (HDR) is a natural DNA repair process that maintains genome integrity through precise correction of DNA damage. Genome editing tools that utilize HDR have enormous therapeutic potential for the correction of loss-of-function disease-causing mutations. Variability in homologous recombination activity is known to exist between genome locations and DNA sequence contexts; thus identifying genomic targets with the highest likelihood of HDR is an important consideration during the development of HDR-mediated therapies. We and others have previously shown that recombinant AAVs (rAAVs) can integrate into a targeted locus by HDR without the use of a nuclease. Here, we report the application of high-throughput rAAV production and locus-wide HDR screens to identify and characterize recombinant integration at specific genomic sites that displayed increased strand cross-over. We created rAAV libraries with 0.1% - 1% base variation across the respective homology arms of >20-donor HDR rAAV plasmids. Next, we employed high-throughput rAAV packaging and *in vitro* transduction of these libraries to create an arrayed rAAV HDR screen. Long-read sequence genotyping analysis of edited alleles allowed for mapping of strand cross-over sites. The accumulated results of strand cross-over exposed potential genomic hotspots of rAAV recombination. In total, these methods represent an approach with the potential to accelerate the screening for HDR sites with improved integration efficiency as well as expand existing knowledge of genome sequence characteristics that favor strand cross-over.

1498 Expanding the Toolbox of Ubiquitous Promoters for Gene Therapy

Joseph Silverberg, Jang Hwan Cho, Mitul Patel, Nathan Youssef, Federico Mingozzi, Daniel M. Cohen, Sean M. Armour

Spark Therapeutics, Inc., Philadelphia, PA

Adeno-associated viruses (AAVs) are a powerful tool in the field of gene therapy for delivering a therapeutic expression cassette. However, AAVs come with unique challenges, especially their limited packaging capacity of approximately < 5kb. Recombinant AAV expression

cassettes must comprise not only a therapeutic transgene, but also regulatory elements that may include a promoter and/or enhancer, an intron, and a polyadenylation signal to maximally enable gene transcription and mRNA expression, as well as ITR sequences. While many commonly-used promoters, such as CAG, often mediate strong ubiquitous expression, these promoters tend to exceed 1kb in length. Promoter size is a significant obstacle for gene augmentation when the therapeutic transgene is greater than or equal to 4kb in length. Efforts to miniaturize ubiquitous promoters have not yet yielded compact sequences with similar potency to CAG. Here, we evaluated the activity levels of several candidate ubiquitous promoters through reporter gene assays in a variety of cell types to select the best candidates for in vivo testing. Promoters that demonstrated strong ubiquitous expression were selected for miniaturization utilizing different promoter bashing techniques, including sequential ablation series, and targeted deletions guided by predictive models for transcription factor binding motifs. In this work, we anticipate identifying strong ubiquitous promoters amenable to miniaturization without compromising transcriptional potency. Additionally, we will map the key motifs contributing to overall promoter activity, as well as investigate whether swapping 5' UTRs or introns may further enable promoter miniaturization. Candidate ubiquitous promoters of less than or equal to 200bp in length will be paired with large payload transgenes (4-4.5kb in length) for assessment of in vivo function in the context of AAVs. The long-term goal will be to test these promoters for their ability to support therapeutically relevant levels of expression of large transgenes, as well as profile their degree of ubiquitous expression in heterogenous tissues, such as the eye and brain, by means of single-cell RNA-seq techniques.

1499 Understanding the Factors That Influence Capsid-Column Affinity and Peak Profile in AEX-HPLC to Measure Empty:Full Ratio

Holly Whitehead, Xinping Xi, Huriye Erdogan Dagdas, James Norton, Bastiaan Leewis
MSAT, MeiraGTx, London, United Kingdom

Anion exchange chromatography by HPLC is an analytical technique that can be used to determine the empty and full capsid content of adeno-associated viral (AAV) vector drug products. AEX columns have a positively charged resin which has a high affinity for negatively charged ions (anions). Under certain conditions, AAV capsids will bind to the column and the introduction of a salt gradient will alter the ionic strength, causing the bound empty capsids to elute first from the column shortly followed by full capsids. This order of elution of the empty and full capsid is due to their slightly different isoelectric points and affinity to the column. Full and empty capsid isoelectric points differ by a pI of approximately 0.2 and so baseline separation of the capsids is a challenge. In addition, the AEX method is sensitive to small changes in chemistry, sample serotype, and environmental conditions which can make developing a reproducible empty:full method difficult. Factors such as sample preparation, mobile phase components, pH, conductivity, salt concentration, and temperature all influence the binding efficiency of AAV capsids onto the column at initial injection and the elution of the empty and full capsids during the salt gradient. Data collected during the development of an AEX empty:full method demonstrates the effects of small method changes on capsid-column affinity and peak profile. AEX results are also compared to results of other orthogonal analytical techniques such as VG/VP ratio, AUC, cIEF, CryoEM, and mass photometry.

1500 Paired HSC Epitope Engineering of CD117 (Ckit) for Antibody-Mediated Autologous Hematopoietic Stem Cell Therapy Conditioning for the Potential Treatment of Hemoglobinopathies

Nandini Mondal, Alexander Harmon, Elizabeth Budak, Kathy Zhang, Jeffrey Wong, Archita Menon, Adam Wolin, Moriah White, Faith Musenge, Adam Camblin, Cristina Baricordi, Brent Coisman, Corrina Lucini, Tao Bai, Kangjian Qiao, Wayne Austin, Michelle DeLelys, Hugh Kromer, Lisa Hardy, Megan Law, Raffi Manoukian, Kiera Fallon, Mudra Patel, Antoinette Cozier, Colin Lazzara, Jeremy Decker, Tanggis Bohnuud, Seung-Joo Lee, Paul Kopesky, Sarah Smith, Charlotte McDonagh, Nicole Gaudelli, Haihua Chu, Adam Hartigan, Giuseppe Ciaramella
Beam Therapeutics, Cambridge, MA

Busulfan and other chemotherapeutic agents are currently used for myeloablative conditioning prior to autologous hematopoietic stem cell transplant (HSCT). Conditioning with these genotoxic agents is often associated with transplant-related morbidity which may significantly limit the use of potentially curative gene therapies for hemoglobinopathies. To overcome this unmet need, we are developing a non-genotoxic conditioning approach where we pair an engineered HSC (eHSC) expressing a modified CD117 epitope with a wild type (WT) CD117-targeted mAb for selectively depleting WT, disease harboring stem cells. We have developed two ESCAPE (Engineered Stem Cell Antibody Paired Evasion) strategies comprising of an eHSC that is multiplex base-edited to contain a CD117 variant edit and a therapeutic edit that can either cause upregulation of HbF, via *HBG1/2* promoter base editing (ESCAPE-1), or directly edit the sickle allele itself by installing a naturally occurring, non-sickling hemoglobin variant Hb G-Makassar (ESCAPE-2). We previously reported that we achieved highly efficient multiplex base editing in HSCs leading to expression of the engineered CD117 epitope with >80% base editing at desired target sites. Our engineered CD117 variants retained WT CD117 biology, binding the natural ligand SCF and exhibited ligand-induced signaling and phosphorylation competency *in vitro*. Our eHSCs also exhibited similar growth and multi-lineage colony formation potential *in vitro,* when compared with WT cells. In addition, eHSCs were capable of long-term multi-lineage hematopoietic reconstitution in rodent models. In parallel, we developed a cognate mAb that exhibited high-affinity binding to WT CD117 but exhibited loss of binding to our engineered CD117 epitopes. mAb binding blocked the interaction of WT CD117 with SCF, thereby selectively suppressing survival of the unedited HSCs. *In vitro* mAb treatment resulted in apoptosis of WT HSCs and led to >85% reduction in viability, while CD117-edited eHSCs remained viable. Importantly, mAb treatment markedly depleted FACS isolated long-term WT HSCs (Lin-CD34+CD38-CD90+CD45RA-) *in vitro*. Fc engineering of the mAb was conducted to generate

versions that reduced mast cell degranulation to baseline levels. We also performed a series of studies to evaluate efficacy of our lead anti-CD117 mAb to deplete WT HSCs and enrich for edited eHSCs *in vivo*. We were able to observe dose-dependent PK properties and receptor occupancy *in vivo*. Importantly, mAb treatment of immunocompromised mice transplanted with mixtures of WT HSCs and multiplex eHSCs harboring our ESCAPE edits resulted in substantial depletion of WT HSCs and concomitant enrichment of human eHSCs, indicating that our mAb was capable of enriching CD117-edited eHSCs *in vivo*. In summary, our ESCAPE strategy may enable non-genotoxic pre-transplant conditioning for autologous cell therapies for the potential treatment of hemoglobinopathies.

1501 Therapeutic Approach of GALV-Based Retroviral Replicating Vectors in Human and Rat Glioma Models

Akihito Inagaki, Sara Collins, Pavlina Chuntova, Maria Barcova, Trishna Patel, Noriyuki Kasahara

University of California, San Francisco, San Francisco, CA

Retroviral replicating vectors (RRV) have shown promising results in early-phase clinical trials of suicide gene therapy. While a multi-center Phase 3 trial of this approach in recurrent high-grade glioma patients did not meet its overall endpoints, highly statistically significant survival was observed in predetermined patient subgroups as compared to matched randomized control patients on standard-of-care treatment, and clinical investigation is on-going. In the present study, we have evaluated Gibbon ape leukemia virus (GALV) as an alternative vector platform. We developed three versions of GALV-based RRV: 1. Full GALV genome-based vector (RRV-GS5), 2. GALV-env pseudotyped MLV vecor (RRV-GC3), 3. GALV-gag-pol-env pseudotyped MLV (RRV-GSC). GALV can infect human and rat cells, so we first evaluated in vitro replication kinetics and found that RRV-GSC could infect and replicate more rapidly in human and rat glioma cells as compared to RRV-GS5 and RRV-GC3. Second, we tested in vitro cytotoxicity using RRV encoding an optimized HSV thymidine kinase enzyme (TKO). RRV-GSC-TKO vector showed ≥50%-90% reduction in cell viability after exposure to Ganciclovir prodrug in the range of 0.1μM-100μM for 5 days. Third, we examined viral stability of RRV-GSC-TKO in human glioma cells by PCR. After 21 days post-infection starting at MOI=0.01, the transgene cassette was stably retained. Finally, in both humanized mouse and syngeneic rat models, RRV-GSC-TKO+Ganciclovir treatment. showed long-term survival without undesired replication in haematopoietic cells and robust tumor growth inhibition by bioluminescence imaging.Hence, this newly developed RRV-GSC-TKO vector shows promise for further translational gene therapy.

1502 Development of a Highly Efficient Modular and Multiplexed CRISPR Editing System for Multimodal Tracking of CAR-T Cells

John J. Kelly[1], Rafael E. Sanchez-Pupo[1], Nourhan Shalaby[1], Ying Xia[1], Francisco M. Martinez[1], Sean W. McRae[1], Qi Qi[2], Matthew S. Fox[2], Justin W. Hicks[2], Jonathan D. Thiessen[2], Timothy J. Scholl[1], John A. Ronald[1]

[1]Robarts Research Inst., University of Western Ontario, London, ON, Canada,[2]Lawson Health Research Institute, London, ON, Canada

Intro: Translationally relevant imaging technologies that allow one to monitor the fate of chimeric antigen receptor (CAR) T cells could enable better predictions of patient response and/or side effects, as well as help evaluate CAR-T designs. Our aim was to develop a highly efficient CRISPR system for editing human T cells with multiple transgenes at loci known to improve both safety and efficacy of CAR-T cells, whilst also making them "visible" with relevant imaging modalities. T cells were edited at the *TRAC* locus to knock-in a CAR and simultaneously knock-out the endogenous T cell receptor (TCR). Human organic anion transporting polypeptide 1B3 (*OATP1B3*) for magnetic resonance imaging (MRI), human sodium iodide symporter (*NIS*) for positron emission tomography (PET) or *Akaluc* for bioluminescence imaging (BLI) were co-engineered into our CRISPR donor vectors to allow for multi-modal *in vivo* imaging of edited CAR-T cells. **Methods:** Human T cells were nucleofected with HiFi spCas9 and gRNAs targeting *TRAC* or *AAVS1* loci. Adeno-associated viral (AAV6) vectors were designed for CD19- or HER2-CAR and reporter gene integration. Editing efficiency was determined by flow cytometry and integration by PCR. CD19+ (NALM6) or HER2+ (SKOV3) cancer cells expressing BLI reporter genes were engineered for CAR-T kill assays and preclinical mouse models. Uptake of the PET tracer [18F]tetrafluoroborate was evaluated in cells expressing NIS. Uptake of the contrast agent Gd-EOB-DTPA into OATP1B3-expressing cells was determined using 3T MRI. BLI was performed on an IVIS imaging system. **Results:** Flow cytometry showed >75% editing efficiency when targeting CAR AAVs to the *TRAC* locus. CD19CAR+/TCR- T cells significantly delayed cancer progression and extended survival in NALM6 and SKOV3 mouse models (Fig. 1). Reporter gene function was confirmed in CAR-OATP1B3 cells with MRI, in CAR-NIS cells with a gamma counter and CAR-Akaluc T cells with BLI. Multiplexing with CAR-OATP1B3/NIS at the *TRAC* locus and NIS/OATP1B3-LNGFR at the *AAVS1* locus together resulted in duel edited cells. Single and dual edited CAR-T cells effectively killed CD19+ and HER2+ cells. Correct integration at *TRAC* and *AAVS1* loci was confirmed by junction PCR analysis. In preclinical mouse models, BLI showed homing of CAR-Akaluc T cells to subcutaneous cancers (Fig. 2 A, B). As few as 1 x10^6 CAR-OATP1B3 cells pre-incubated with Gd-EOB-DTPA could be detected in subcutaneous intratumoral injections with 3T MRI (Fig. 2C). **Conclusion:** Our work describes a CRISPR-Cas system for highly efficient, modular editing of T cells with a CAR and preclinical and/or clinically relevant human reporter genes. These advanced CRISPR tools should have broad utility for co-editing primary cells with therapeutic genes and reporter genes to make trackable therapeutic cells with improved efficacy and safety profiles.

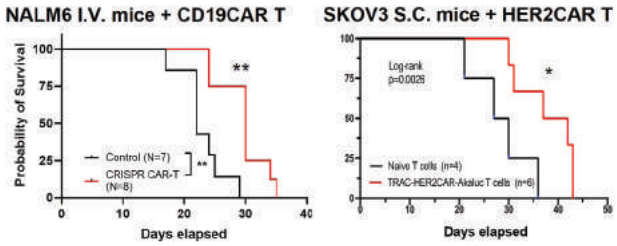


Fig.1. Significantly increased survival in NALM6 (leukemia) and SKOV3 (ovarian) cancer models treated with CD19CAR or HER2CAR T cells.

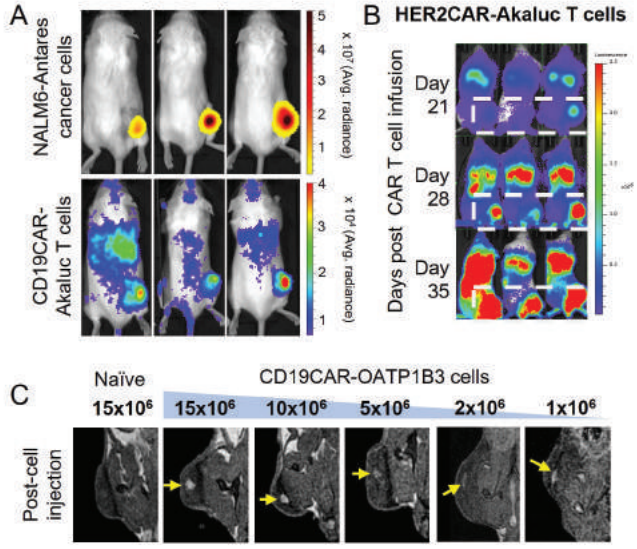

Fig.2. A) Dual BLI CAR-T cell tracking model of I.V. administered CD19CAR-Akaluc T cells homing to NALM6-Antares lesions. B) HER2CAR-Akaluc T cells homing to and expanding at SKOV3 ovarian cancer tumour lesions (dashed boxes). C) CD19CAR-OATP1B3 cells pre-incubated with Gd-EOB-DTPA showing positive contrast down to 1x10^6 cells injected intratumorally.

1503 Combining Vectorized Antibody and miRNA Lowering Strategies for Synucleinopathies

Seya Acar-Broekmans, Rhode Erbrink, Nikki Timmer, Charlot Van Rooijen, Sebastian Kieper, Verena Hehle, Astrid Vallès

uniQure Biopharma BV, Amsterdam, Netherlands

Synucleinopathies are neurodegenerative disorders characterized by aggregation of alpha-synuclein protein (α-Syn), encoded by the SNCA (Synuclein Alpha) gene. With only some symptomatic therapies, no disease modifying treatments are available for any of the synucleinopathies. There is an immediate need to tackle the underlying pathophysiology in these diseases. Aggregated α-Syn is one of the main components of Lewy Bodies (LBs), the key neuropathological hallmarks in Parkinson's disease (PD) and Lewy Body Dementia (LBD), and of Glial Cytoplasmic Inclusions (GCI), characteristic of multiple system atrophy (MSA). The α-Syn aggregates may spread in a prion-like manner, with toxic aggregated forms being transmitted from cell-to-cell as the disease progresses. This toxic cycle can be potentially halted by decreasing the α-Syn protein levels or by facilitating the clearance of the α-Syn aggregates outside of the cell. We are developing two complementary AAV-based gene therapy approaches targeting α-Syn pathology. First, we are advancing an engineered miRNA-based approach, using our miQURE® platform, where we lower SNCA mRNA and α-Syn protein levels. We have previously shown proof-of-concept (PoC) of our SNCA-targeting miQURE approach in relevant preclinical PD models. Second, we are using our AbQURE™ platform technology for expression and secretion of vectorized, α-Syn targeting antibodies. Finally, we have combined miQURE® and AbQURE™ approaches in our GoQURE™ platform, in which we express a SNCA targeting engineered miRNA and a α-Syn targeting antibody from the same construct. Here, we have established *in vitro* PoC for AbQURE™ and GoQURE™ platforms for synucleinopathies. Two different antibodies targeting the C-terminal part of α-Syn were successfully expressed in our AbQURE™platform (AbQURE-1 and AbQURE-2). Next, these antibodies were combined with our SNCA-targeting miQURE approach in the GoQURE™ platform (GoQURE-1 and GoQURE-2). Functional antibodies were expressed in the HEK293T and SH-SY5Y cells after transfection with the plasmids carrying either the AbQURE™ or GoQURE™ constructs. Both the cell extracts and the medium of the cells were analyzed for presence of total and functional antibodies using in-house developed MSD assays. Results show that 96% of the antibodies expressed are secreted efficiently into the medium of both HEK293T and SH-SY5Y cells. The AbQURE™constructs were further packaged into AAVs and functional antibodies were successfully expressed from an AAV-AbQURE™after transduction in SH-SY5Y cells. Moreover, the SNCA-targeting miQURE encoded in the GoQURE™ constructs could also be expressed as well as the α-Syn-antibody. The present in vitro PoM results show the potential of our GoQURE™ platform to express both an engineered miRNA targeting SNCA and an α-Syn-targeting antibody from a single construct, to reduce intracellular α-Syn and target extracellular α-Syn aggregates, and ultimately decrease α-Syn toxicity in synucleinopathies. *miQURE is a registered trademark in the US and other jurisdictions; AbQURE and GoQURE are trademarks registered in the European Union and United Kingdom and pending in other jurisdictions.*

1504 Optimization of AAV Sample Preparation towards Accurate Quantification of Viral Titer by dPCR

Bella Neufeld

Research and Development, Teknova, Hollister, CA

For AAV applications ranging from research tools to clinical-stage gene therapeutic strategies, the ability to quantify AAV vector concentration precisely and reproducibly is crucial. While several analytical methods are available, digital polymerase chain reaction (dPCR) is one of the most robust and reliable ways to determine absolute quantification of viral DNA at various stages of production. To ensure accurate titer measurements by dPCR from transgene DNA, unpurified AAV samples require DNase-I treatment to remove exogenous DNA prior to capsid disruption. Multiple factors, such as EDTA concentration and the DNase activation and inactivation method, can significantly impair the amplification efficiency of the protected viral vector genome. This highlights the potential for large discrepancies between the results of

different laboratories using analogous protocols. In this study, using a design of experiments approach, we have extrapolated an optimal DNase-I application that can be used as a standard dPCR treatment for AAVs. We determined the best concentration of EDTA to allow the inactivation of DNase-I, while not inhibiting the dPCR reaction following the treatment. Based on our findings, we have established a select protocol for processing AAV samples prior to dPCR.

1506 Efficacy of SKG0402 Gene Therapy in Fabry Disease Mouse Models

Jiao Yue, Jingyi Yang, Yanjun Liu, Xia Liu, Yanjun Shen, Yu Wu, Ruoyan Hu, Xing Ding, Li Wang, Carol Huang, Ting Yu, Jay Hou

Skyline Therapeutics, Cambridge, MA

Fabry disease is an X-linked lysosomal storage disease caused by loss-of-function mutations in the *GLA* gene encoding alpha galactosidase A (α-Gal A). Deficiency of α-Gal A leads to accumulation of globotriaosylceramide (Gb3) and globotriaosylsphingosine (lyso-Gb3) in lysosomes of various cells throughout the body, resulting in a multisystemic life-threatening pathology including renal failure and cardiac disease. Current standard of care, enzyme replacement therapy (ERT), requires bi-weekly injections and has limited therapeutic effect because of poor cross-correction of renal and cardiac symptoms. To address these challenges, we developed SKG0402, an AAV9 gene therapy delivering a codon optimized human *GLA* transgene driven by a ubiquitous promoter. Intravenous administration of SKG0402 in *Gla* KO mice resulted in increased activity of human α-Gal A in a dose-dependent manner in the plasma and a variety of tissues including liver, heart and kidney. Importantly, the toxic Gb3 accumulation in these tissues was significantly decreased. Moreover, the 6-month long-term study demonstrated a sustained GLA transgene expression and durable Gb3 clearance. Additionally, we evaluated the efficacy of SKG0402 in an aggravated murine model of Fabry disease. Intravenous administration of SKG0402 in this mouse model improved survival, body weight, thermosensory and kidney functions. Severe adverse effect was not observed in all the studies performed, suggesting that the treatment with the vector was safe. Collectively, the results suggest that intravenous administration of SKG0402 may be a promising therapeutic strategy for the treatment of Fabry disease.

1507 Enhancing CRISPR Genome Editing by Extensive Chemical Modification and Self-Delivery of Guide RNAs

Scot A. Wolfe[1], Nadia Amrani[1], Nathan Bamidele[1], Julia Alterman[1], Zexiang Chen[1], Gitali Devi[1], Dimas Echeverria-Moreno[1], Hailey Feinzig[1], Nicholas Gaston[1], Karin Kelly[1], Zachary Kennedy[1], Pengpeng Liu[1], Socheata Ly[1], Stacy Maitland[1], Karthikeyan Ponnienselvan[1], Julia Rembetsy-Brown[1], Kathy Snow[2], Han Zhang[1], Cathleen Lutz[2], Stephen Murray[2], Anastasia Khvorova[1], Erik Sontheimer[1], Jonathan K. Watts[1]

[1]UMass Chan Medical School, Worcester, MA,[2]The Jackson Laboratory, Bar Harbor, ME

Therapeutic genome editing using CRISPR-based reagents are rapidly moving to the clinic. *Ex vivo* genome editing can be potent with standard genome editing reagents (e.g. Cas9 protein or mRNA co-delivered with synthetic end-protected guide RNAs) and is currently being used successfully in clinical trials. However, therapeutic treatment of many genetic diseases will require the editing of cells and tissues directly within the patient's body. The *in vivo* activity of CRISPR reagents can be improved through partial chemical modifications of the backbone that stabilize the guide RNA from hydrolysis by endogenous nucleases (e.g. Finn, J. D. et al. *Cell Reports* 22, 2227-2235 (2018)). However, partially protected RNAs have a short half-life *in vivo* unless protected (e.g. via lipid nanoparticles). In addition, selective targeting of many tissues remains challenging with existing delivery modalities and unmodified RNA segments can stimulate counterproductive immune responses. Our strategy to improve the safety and efficiency of genome editing *in vivo* relies on the development of fully modified (FM), conjugated guide RNAs that can be delivered in a tissue-specific fashion as RNPs with the effector Cas9 protein, or co-delivered with an AAV vector expressing the effector protein and the tracrRNA. Chemical modification of the guide RNA will increase guide stability and potency, improve biodistribution, reduce immune responses, and eliminate the need for lipid nanoparticle formulation. We previously described our first generation of heavily modified (HM) crRNAs and tracrRNAs that can support effective SpyCas9 activity in mammalian cells. We have now demonstrated that our HM crRNA/tracrRNA can support efficient editing *in vivo* when directly injected into the mouse CNS as SpyCas9 RNP. We have also extended these approaches to base editors and to additional Cas9 homologues with distinct PAM specificities. Moreover, we defined new variants of HM and FM crRNA frameworks with improved Cas9 genome editing in mammalian cells and validated these guides for self-delivery in conjunction with AAV vectors that encode Cas9 and tracrRNA. This strategy promises to be particularly useful for multiplex targeting and inactivation of the AAV episome after editing is achieved, thereby minimizing genotoxicity and immune responses that could be caused by prolonged Cas9 expression.

1508 Fine-Tuning of the pH-Responsiveness of Cationic Copolymer via Amino Acid and Piperazine Substitutions for Adenovirus Delivery

Chae-Ok Yun[1,2], Jeongmin Lee[2], A-Rum Yoon[1], Dayanada Kasala[1]

[1]Hanyang University, Seoul, Korea, Republic of,[2]GeneMedicine, Seoul, Korea, Republic of

Recombinant adenoviruses (Ads) and oncolytic Ads show great potential for cancer gene therapy. However, inherent properties of Ads, like coxsackie and adenovirus receptor (CAR)-dependent endocytosis, limit their use in clinical environment where heterogenic tumors express variable expression level of CAR. To address this limitation, a pH- and glutathione-responsive poly(ethylene glycol)-poly(β-aminoester)-polyethyleneimine (PPA) was developed for conjugation with Ad. The pH sensitivity of the PPA copolymer was elegantly tuned by comparatively evaluating different amino acids (arginine, histidine, and tryptophan), piperazines (Pip1, Pip2, and Pip3), and guanidine residues in the backbone of the PPA polymer. PPA copolymer was further functionalized with bioreducible cross-linker succinimidyl 3-(2-pyridyldithio) propionate) (SPDP) to obtain PPA-SPDP to facilitate conjugation with thiolated Ad (Ad-SH), generating PPA-conjugated Ad (PPA-Ad). Ad-SH was prepared by reacting Ad with 2-iminothiolane. The size distribution and zeta potential of PPA-Ad conjugates generated with higher Ad:polymer molar ratios resulted in polymer concentration-dependent increase in both the hydrodynamic diameter and surface charge of the conjugates. The transduction efficiency of PPA-Ad conjugates in CAR-positive cells (A549 and H460 cells) was remarkably increased at the acidic pH condition mimicking those of tumor microenvironment (pH 6.2) when compared with PPA-Ad conjugate incubated under the physiological condition (pH 7.4), demonstrating its pH-dependent enhancement in cell entry. The increase in transduction efficiency was even higher for PPA-Ad conjugates in CAR-negative cells (MDA-MB-231 and T24 cells). Collectively, these results demonstrated that biocompatible and biodegradable PPA copolymers can efficiently cover the surface of Ad and increase its transduction efficiency in a pH-dependent manner.

1509 Development of a Novel Helper Plasmid: One Step Closer to the Next Generation rAAV Vectors

Eric Mauro, Jonathan Havard, Mathieu Porte, Laure Robert, Carine Morel, Sylvain Julien, Patrick Erbacher

Polyplus, Illkirch, France

Harnessing rAAVs as viral vectors for therapeutic transgene delivery still requires improvements in yields and specificity to lower vector doses, and therefore manufacturing cost, as well as to improve patient safety. To this end, our research is focused on developing novel technologies to ensure manufacturing of high yielding rAAV particles using transient transfection, as well as enhancing viral particles quality and specificity. Here we present our state-of-the art approach to design new helper plasmids (pHelpers) with the aim of improving both the genomic titers and the infectivity (TU/mL) of the viral particle obtained from suspension cultures. We took the opportunity to exploit our proprietary DNA assembly method technology to explore the synergies of multiple genetic features modularly assembled in synthetic plasmids. Comparison of the biological activity of several versions of rationally designed pHelpers led us to identify the optimal configuration able to outperform existing helper plasmids in several bioproduction conditions. Our expertise in DNA plasmid design and assembly together with our scalable transfection solutions for rAAV manufacturing give us the potential to improve both productivity and specificity of gene therapy products.

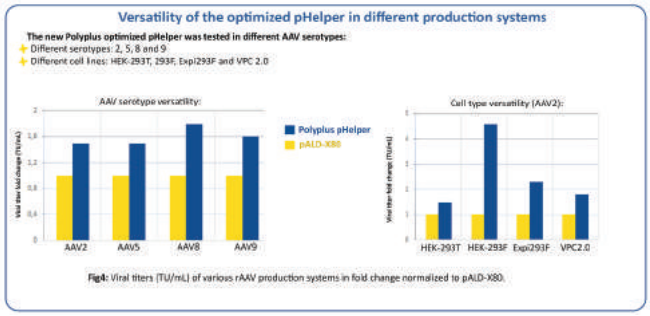

Fig4: Viral titers (TU/mL) of various rAAV production systems in fold change normalized to pALD-X80.

1510 CRISPR/Cas9 Based Genome Editing to Replace the Full-Length CFTR cDNA Shows Promising Restoration of CFTR Function and Safety in Pre-Clinical Studies

Sriram Vaidyanathan[1], Alekh Paranjapye[2], Jenny L. Kerschner[3], Adrian J. Thrasher[4], Giandomenico Turchiano[5], Ann Harris[3], Matthew H. Porteus[6]

[1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]Genetics, University of Pennsylvania, Philadelphia, PA,[3]Genetics and Genomic Sciences, Case Western Reserve University, Cleveland, OH,[4]UCL Institute of Child Health, London, United Kingdom,[5]Great Ormond Street Institute of Child Health, University College London, London, United Kingdom,[6]Stanford University School of Medicine, Stanford, CA

Cystic fibrosis (CF) is caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. An autologous gene corrected airway stem cell therapy has been proposed to treat CF. The insertion of the CFTR cDNA along with a cassette expressing truncated CD19 (tCD19) in exon 1 of the CFTR gene followed by enrichment of the edited airway stem cells has been previously demonstrated to produce differentiated epithelial sheets with restored CFTR function that is comparable to non-CF controls. This Universal CFTR correction strategy (Universal strategy) can benefit almost all CF patients regardless of the causal mutation. In this study, we further characterize the safety and potency of the edited airway stem cells by characterizing the frequency of aberrant genetic rearrangements using CAST-seq, the open chromatin profile of the CFTR locus after editing using ATAC-seq and the regenerative potential of the corrected airway stem cells using single cell RNA sequencing (scRNA-seq). Using CAST-seq, translocations were observed in <0.1% of alleles and large INDELs were observed in ~1% of alleles in cells treated using the sgRNA targeting Cas9 to the ATG site of CFTR. The translocation was mapped to a known non-oncogenic off-target site that was previously reported. Human bronchial epithelial cells (HBECs) were edited using the Universal strategy and enriched to obtain populations with >70% edited cells. Upon differentiation, edited airway cells showed CFTR

function that was 127±74% relative to non-CF controls. There was no noticeable difference in the open chromatin profile of the CFTR locus between differentiated airway epithelial cells from edited and control samples apart from the region corresponding to the tCD19 cassette. Lastly, edited HBECs from each donor produced the same types of airway cells produced by control HBECs from the same donor. Analysis of differential gene expression between edited and control samples across all three donors is ongoing. Overall, our results indicate the Universal strategy does not cause adverse genomic or regulatory changes and does not limit the regenerative potential of airway stem cells.

1511 A Novel AAV RNA Based Infectivity Reporter Assay

Bella Neufeld

Research and Development, Teknova, Hollister, CA

The infectivity of an AAV virus sample is measured by the endpoint dilution assay, which estimates the number of viruses to infect cell culture 50% of the time. The commonly used methods to estimate the median tissue culture infectious dose (TCID50) from the assay's outcome are difficult to validate, use, and quantify. Due to requirements for sample preparations, the assay is subjected to systematic error from the presence of plasmids and other nucleic acids at different points in the manufacturing process. Here we demonstrate a novel cell-based infectivity assay that measures the ability of the AAV to infect HEK293 cells. The assay uses a novel method for tagging AAV transgene's RNA and results in the expression of a fluorescent protein reporter upon transgene transcription. A 125 bp RNA tag is generated by placing a new RNA sensor module (non-coding RNA) into the post-transcriptional terminator region of the transgene. We exploit the molecular mechanism RNA pol-II transcriptional elongation beyond the terminator sequence to concurrently transcribe non-coding RNA (ncRNA) with the coding sequence of the upstream gene. As a next step, the ncRNA gets processed by the genetic machinery encoded in the engineered HEK293 cell and mediates the activation of the fluorescent reporter in a manner that reflects the activity of the gene of interest (GOI). Adding an ncRNA sequence does not involve changes to the GOI coding sequence, therefore it does not alter the packaging, regulation, or stability of GOI expression. Our data demonstrate that novel infectivity reporter assay can significantly facilitate improvements in process development workflows for both upstream and downstream optimization.

1512 Non-Viral Delivery of *ABCA4* to Photoreceptors

Gayathri Ramaswamy, Cathleen Gonzales, Robert Farra, Jaka Cemazar, Christopher Magnin, Meisam Bakhshayeshi, Ricardo Saldana-Meyer, Jose Lora

Intergalactic Therapeutics, Cambridge, MA

Introduction: *ABCA4*-related retinopathies, including Stargardt disease, cone-rod dystrophy, and retinitis pigmentosa, are associated with mutations in the *ABCA4* gene. More than 900 mutations have been described. ABCA4 protein is localized to the outer segments of photoreceptors, and the gene encodes an importer flippase protein that prevents the accumulation of material toxic to the retinal pigment epithelium (RPE). Specifically, mutations in the *ABCA4* gene result in a build-up of lipofuscin, leading to degeneration of the RPE and subsequently, loss of photoreceptor cells. Replacement with wild type ABCA4 protein via gene therapy may slow or block disease progression. Due to the large size of the coding region (~7 kb), delivery of full length *ABCA4* is not amenable by commonly used adeno-associated virus (AAV) gene therapy platforms. Non-viral gene delivery lacks this cargo size limitation, making it an ideal approach for ABCA4 gene therapy. **Methods:** We generated covalently closed and circular DNA (C^3DNA) for codon optimized full-length human *ABCA4* and delivered it subretinally to adult porcine eyes followed by application of COMET, a proprietary electrotransfer device. **Results:** Human ABCA4 mRNA and protein expression were detected by qPCR and immunohistochemistry (IHC), respectively, at 5-6 days post-treatment. Dual labeling studies further identified the cellular and subcellular location of transgene-derived ABCA4 protein to be primarily in the outer segments of photoreceptors. Importantly, when compared to porcine ABCA4 protein, the expression pattern of human ABCA4 mimicked that of the endogenous protein. Subretinal injection requires ocular surgery that is not amenable to frequent dosing, therefore it was critical that we demonstrate long-term protein expression. We conducted a series of persistence studies in porcine retina to assess the durability of human ABCA4 protein expression. After one single subretinal injection of C^3DNA-*ABCA4*, human ABCA4 protein was readily detected in the outer segments of photoreceptors at 1, 3, 6 and 12 months, the longest time point evaluated to date. This data supports persistence of transgene-derived ABCA4 protein at least to 12 months post-treatment using Intergalactic's non-viral C^3DNA plus COMET gene delivery platform. **Conclusion:** We have demonstrated feasibility of COMET-mediated delivery of non-viral C^3DNA expressing the full length human *ABCA4* gene to relevant cell types in the retina and demonstrated the expression of human ABCA4 protein that persists at least to 12 months post-treatment in adult porcine retina.

1513 Banana Lectin H84T CARs Augment the Cytotoxic Activity of Conventional CAR T-cell Therapies to Target Multiple Solid Tumors and Their Cancer Associated Stroma

Ada Irmak Ozcan[1], Mary Kathryn McKenna[1], Challice Bonifant[2], David M. Markovitz[3], Malcolm K. Brenner[1]

[1]Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX,[2]Oncology, Johns Hopkins University School of Medicine, Baltimore, MD,[3]Department of Infectious Diseases, University of Michigan, Ann Arbor, MI

The heterogenous and dynamic expression of tumor antigens on malignant cells and the physical barrier provided by the associated fibrotic stroma significantly hinder the success of current immunotherapies targeting solid tumors. To overcome these hurdles, we have developed a lectin-based chimeric antigen receptor (CAR) that recognizes and binds to distinct patterns of aberrant glycosylation (high mannose) specifically expressed on tumor cells and the surrounding stroma. To reduce the potential of antigen escape, we simultaneously target conventional tumor associated antigens and aberrant glycan patterns expressed on multiple types of malignant cells. We have previously demonstrated that T cells expressing a CAR with a binder

based on a modified banana-lectin (H84T BanLec) can recognize high mannose glycans expressed on pancreatic adenocarcinoma cells and tumor stellate cells and produce anti-tumor effects in both tumor spheroid and in vivo models. Since aberrant glycosylation patterns are a hallmark of cancer and are widely present on many different tumors, we hypothesized that incorporating H84T BanLec as part of a chimeric antigen receptor and expressing the construct in T cells that have been engineered to target other tumor antigens would broadly boost the efficacy of currently available immune effector cell therapies. We now show that H84T CAR expressing T-cells can effectively target and eliminate non-small cell lung cancer (NSCLC), osteosarcoma, and breast carcinoma cells both in monolayer cultures and in 3-dimensional spheroids composed of tumor cells and cancer fibroblasts. When H84T CARs are co-expressed with a conventional scFv -derived CAR targeting HER.2 we observe superior anti-tumor activity, compared to HER.2 CAR T cells alone, in the setting of NSCLC co-cultures (Figure 1) and tumor spheroid assays (Figure 2). Similarly, GD2/H84T dual CAR-T cells demonstrate greater cytotoxicity against osteosarcoma in the presence of its stromal support cells than any single CAR expressing T cell. Thus, H84T BanLec CAR T cells provide a tool to target the aberrant glycosylation patterns of malignant cells and their supporting stroma, potentially offering a broadly effective treatment option for multiple heterogenous solid tumors. We are now elucidating the underlying mechanisms by which H84T CARs induce stromal disruption and enhance tumor infiltration.

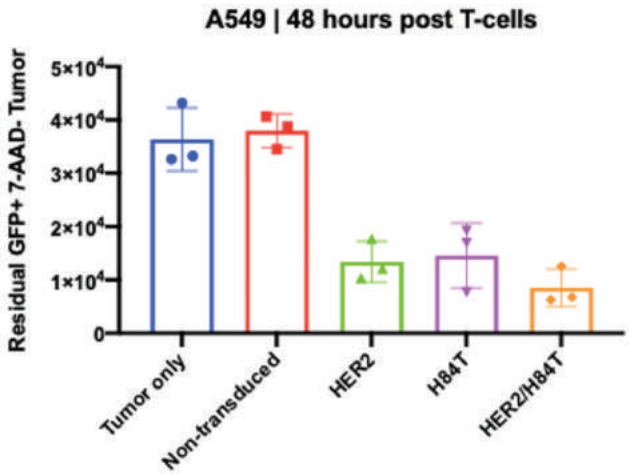

Figure 1. Dual HER2/H84T CAR T cells kill tumor better than single CARs. A549 non-small cell lung cancer co-culture data quantifying viable tumor cell count 48 hours after T cell addition. The tumor cells were transduced to express green fluorescent protein (GFP) and viable cells were selected by negative 7-AAD staining on Flow Cytometry.

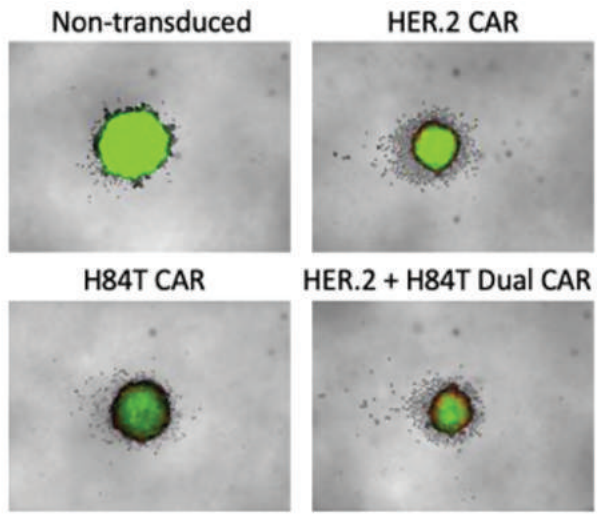

Figure 2. Dual HER2/H84T CAR T cells reduce tumor signal in 3D spheroids. A549 GFP tumor spheroid images 94 hours post T cell addition as obtained by IncuCyte Live Cell Analysis System. Annexin V-Alexa Fluor 594 conjugate was used as a marker for apoptosis and can be seen in red.

1514 Muopolysaccharidosis Type I Skeletal Alterations and Cross Correction in an *Ex Vivo* Gene Therapy Approach

Ludovica Santi[1], Stefania Crippa[1], Valentina Capo[1], Sara Penna[1], Giada De Ponti[1], Gaia Alberti[1], Margherita Berti[1], Tommaso Basini[1], Giulia Consiglieri[2], Francesca Tucci[2], Mara Riminucci[3], Alessandro Corsi[3], Andrea Barbero[4], Silvia Lopa[5], Ivan Martin[4], Matteo Moretti[5], Bernhard Gentner[1], Alessandro Aiuti[1], Anna Villa[1], Maria Ester Bernardo[1]

[1]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy,[2]Pediatric Immunohematology and Bone Marrow Transplantation Unit, Milan, Italy,[3]Department of Molecular Medicine Sapienza University, Rome, Italy,[4]Tissue Engineering Department of Biomedicine, Basel, Switzerland,[5]Cell and Tissue Engineering Laboratory, Milan, Italy

Dysostosis multiplex, one of the most prominent clinical manifestations of Mucopolysaccharidosis type I Hurler (MPSIH) patients, remains an unmet clinical need since it is not cured by the standard hematopoietic stem cell transplantation (HSCT) approach. The primary effect of the α-L-iduronidase (IDUA) enzyme deficiency is the widespread accumulation of glycosaminoglycans (GAGs) leading to a cascade of secondary events which affect cellular and extracellular functions.

The phase I/II hematopoietic stem cell-gene therapy (GT) trial (NCT03488394), involving 8 patients and currently ongoing at SR-TIGET, shows extensive metabolic correction and initial skeletal stabilization. Due to the poorly defined bone pathogenesis and bone correction after GT, we investigated the role and properties of skeletal compartment cells, i.e. mesenchymal stromal cells (MSCs), chondrocytes (CHs), osteoblasts (OBs), and osteoclasts (OCs) obtained from MPSIH patients enrolled in the trial before and after GT. The *in vitro* characterization and functionality of patient-derived MSCs and OCs were not altered by IDUA deficiency. Although MPSIH-MSCs, isolated before and after GT normally underwent the *in vitro* intramembraneous ossification process, MPSIH-OBs showed intracellular GAGs accumulation. Patient-derived gene corrected OCs, showing supraphysiologic enzyme activity levels, could cross-correct non-hematopoietic cells by releasing the IDUA enzyme. Due to the ability of MPSIH OBs to uptake the IDUA enzyme when exposed to the supernatant of patient gene-corrected OCs, mainly via mannose-6-phospate receptor (M6PR), GAG accumulation found in MPSIH-OBs was completely reversed, demonstrating the feasibility of cross-correction. Patient-derived osteomedullary biopsies (BOMs) displayed a reduced expression of type I collagen and a morphological disorganization of CHs. To deeply investigate this phenomenon, our *in vitro* 3D model of hypertrophic cartilage assessed whether patient-derived MSCs are able to generate *de novo* bone tissue after subcutaneous implantation in MPSI immunodeficient mice. In detail, the specific stainings such as Safranin, Alizarin, Picrosirius Red, together with immunohistochemistry will allow the assessment of the endochondral ossification process of MPSIH cells. Moreover, MPSIH BOMs before GT showed enthesopathy, with enlarged and vacuolated cells, that was improved and rescued in the one year post GT samples. To better characterize this feature, the enthesopathy was studied in the Achilles tendons of untreated MPSI mice, showing progressive vacuolization, matrix mineralization and calcification. Pico-CT and histomorphological analyses of MPSI mice long bones revealed a reduced number of OBs but an increased functionality, measured as bone formation rate. In addition, as early as 2 months of age, the growth plate of MPSI mice long bones showed swollen CHs and disorganization in the zone architecture. We will further study the pathogenetic mechanisms of bone damage and the skeletal correction after GT using both patient and mouse samples in order to provide a broader understanding of disease-specific mechanisms and to support clinical data.

1515 MAdCAM-1-Directed CARs Are a Novel Means of Targeting a Regulatory T Cell Therapy for Inflammatory Bowel Disease

Jessica Wang, Soo Park, Shouvonik Sengupta, Erin O'Brien, Magelda Montoya Cruz, Jazmin Bravo, Bryant Chau, Shairaz Shah, Amanda Goodsell, Jennifer Zeng, Faye Wu, Jordan Tsai, Lih-Yun Hsu, Brandon Kwong, Dominic C. Borie, Jeffrey Greve, John K. Lee, Charles Kaplan, Ashley E. Mahne

Kyverna Therapeutics, Emeryville, CA

Introduction: Regulatory T cells (Tregs) are an attractive therapy for inflammatory bowel disease (IBD). Two major limitations in achieving widespread clinical use of Tregs are 1) the difficulties inherent in isolating and expanding pure populations of Tregs and (2), the polyclonal repertoire of Tregs, which lacks the specificity needed to maximize disease-targeted efficacy. We sought to address these challenges in the context of creating a cell therapy for IBD by directing a novel synthetic regulatory T cell platform (synRegs) to inflamed intestinal tissue via a chimeric antigen receptor (CAR) directed against the intestinal endothelial cell adhesion molecule MAdCAM-1. **Methods and Results**: Immunohistochemical analysis of intestinal samples from ulcerative colitis (UC) and Crohn's disease (CD) patients confirmed MAdCAM-1 expression in inflamed intestinal tissue and secondary lymphoid tissues. While this high level of tissue specificity makes MAdCAM-1 an attractive target for directing CAR-synRegs to the inflamed intestine, we recognized that the complex process of transendothelial migration was likely highly dependent on CAR scFV affinity that could impact migration of CAR-synRegs into the tissue. To mitigate this risk, phage panning and rabbit immunization campaigns were executed in parallel to obtain 64 human MAdCAM-1-specific antibodies with a wide range of binding affinities. These anti-MAdCAM-1 scFvs were reformatted as CARs, transduced into primary $CD3^+$ T cells using lentivirus, and screened for cell surface expression and CAR-specific T cell activation following target antigen exposure. Lead CAR candidates of varying binding epitopes and affinities were tested in an in vitro transendothelial migration assay under shear flow conditions. Critically, MAdCAM-1 CAR expression enhanced T cell binding to and migration through a $MAdCAM\text{-}1^+$ endothelial monolayer. Transmigration levels for T cells expressing certain MAdCAM-1 CARs surpassed that observed in positive control T cells expressing integrin α4β7, the natural receptor for MAdCAM-1. In vivo, human MAdCAM-1-CAR synRegs displayed preferential accumulation relative to untargeted synRegs in NSG mice bearing $MAdCAM\text{-}1^+$ tumors over the course of a two-week follow-up. Moreover, short-term homing studies also confirmed tissue entry of human MAdCAM-1-CAR synRegs into the inflamed colon of hMAdCAM-1 knock-in mice with DSS-induced colitis. **Conclusions**: MAdCAM-1 is a validated CAR target for the directing of synRegs to the inflamed intestinal tissues of IBD patients. We have identified lead binding domains that mediate antigen-specific T cell activation and promote migration across $MAdCAM\text{-}1^+$ endothelium both in vitro and in vivo, thus supporting further development of this means of targeting CAR-synRegs for the treatment of IBD.

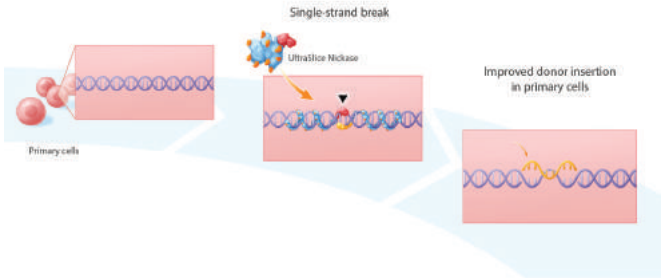
1516 Gene Editing Proteins with Nickase Functionality Enable Scarless Targeted Gene Insertion in Primary Human Cells

Elizabeth Belcher[1], Taeyun Kim[2], Kyle M. Garland[1], Christopher B. Rohde[2], Matthew Angel[1,2]

[1]Eterna Therapeutics Inc., Cambridge, MA,[2]Factor Bioscience Inc., Cambridge, MA

Many gene editing strategies involve the use of nucleases to generate targeted double-strand breaks (DSBs) in genomic DNA, which is often associated with cytotoxicity and off-target effects that can prevent clinical translation. Such undesirable outcomes have led to the development of gene-editing nickases, which instead create targeted single-strand breaks (SSBs) that favor high-fidelity repair through the homology-directed repair (HDR) pathway rather than the more error-prone non-homologous end joining (NHEJ) pathway. Here, we

explore the use of UltraSlice gene editing proteins containing cleavage domain variants with nickase functionality for targeted insertion of donor sequences into a defined genomic locus. Using UltraSlice gene editing proteins targeting exon 73 in *COL7A1* (mutations in which cause dystrophic epidermolysis bullosa), we tested combinations of 3 mutations previously reported to confer nickase functionality to the catalytic domain of FokI, a Type IIS restriction endonuclease (D450A, D450N, and D467A). Notably, we found that D450A and D450N resulted in significantly reduced NHEJ relative to the *COL7A1_e73* UltraSlice pair with a wild-type FokI cleavage domain, with D450N exhibiting the least amount of NHEJ. We confirmed these results with Sanger Sequencing, comparing the D450N-treated PCR amplicon to a wild-type *COL7A1* PCR amplicon and observed no significant alteration of the genomic target site. We then compared the ability of nickases to insert a 300 bp dsDNA donor sequence via electroporation into primary human fibroblasts. Insertion band intensities showed high insertion efficiencies for D450A and D450N (58.7% and 42.9%, respectively), though lower than standard UltraSlice (72.3%). Our data demonstrate that gene-editing nickases enable scarless insertion of donor sequences into defined genomic loci, and thus may have the potential to improve the safety of *in vivo* gene insertion by reducing off-target effects.



1517 Non-Viral RNA-Lipid Nanoparticles for High Efficiency Genome Editing of CD34+ Hematopoietic Stem and Progenitor Cells for Advanced Cell and Gene Therapies

Samuel Clarke, Stella Park, Aruna Balgi, Rita Zhao, Meenakshi Swaminathan, Nikita Jain, Anitha Thomas, Angela Zhang, Reka Geczy

Precision NanoSystems, Vancouver, BC, Canada

Background and Aims: The application of CRISPR-Cas9 gene editing in hematopoietic stem (HSC) and progenitor cells (HSPCs) has the potential to revolutionize the treatment of genetic blood disorders by correcting disease-causing mutations. Previously, we demonstrated the utility of a novel lipid nanoparticle (LNP) reagent for the multiplexed engineering of gene-edited CAR T cells, showing high cell viabilities, rapid onset editing, and potent CAR-mediated killing. In this current work, we demonstrate the capability of LNPs for the efficient and gentle delivery of genetic material to CD34+ HSPCs. The benefits of a non-viral LNP-mediated approach paves the way for the development of next generation gene therapy products in the HSC field. **Methods:** LNPs encapsulating S.p. Cas9 mRNA and CD33 or CD45 targeted guide RNA (sgRNA) were produced using the scalable NanoAssemblr® NxGen™ microfluidic platform technology (Fig. 1A). The LNP composition was optimized for the gentle and efficient cargo delivery to HSC/HSPCs. Purified human CD34+ cells were cultured, stimulated, and treated by the direct addition of the RNA-LNPs. Various commercial cell sources were tested including mobilized peripheral blood and cord blood. Gene knockout and viability were assessed using flow cytometry, cell proliferation using an automated cell counter, and differentiation capacity by colony-forming unit (CFU) assays. **Results:** One-step addition of LNPs to CD34+ HSPCs resulted in 84 ± 6% CD33 and 81 ± 2% CD45 knockout efficiencies (n=6 CD34+ donors, Fig. 1B). After treatment, cells maintained on average 95 ± 3% absolute cell viability, compared to 99% viability of the untreated cells, Fig. 1C. Furthermore, LNP treated HSCs maintained excellent cell proliferation, with over >90% relative cell proliferation to the untreated controls. The CFU assays showed no significant change in relative lineage formation for both the RNA-LNPs and the empty LNP vehicle control (Fig. 1D). Finally, LNP production was successfully scaled-up using microfluidics from discovery to pre-clinical scales. Conclusions: LNP-mediated CRISPR-Cas9 mRNA delivery is a promising approach for gene editing in HSPCs. The simple and gentle nature of LNP cell treatment allows for multiple genetic engineering steps for simultaneous expression and deletion of proteins for novel gene therapies. Furthermore, LNPs can be easily manufactured using microfluidics, enabling small-scale screening of RNA libraries and rapid scale-up for clinical translation.

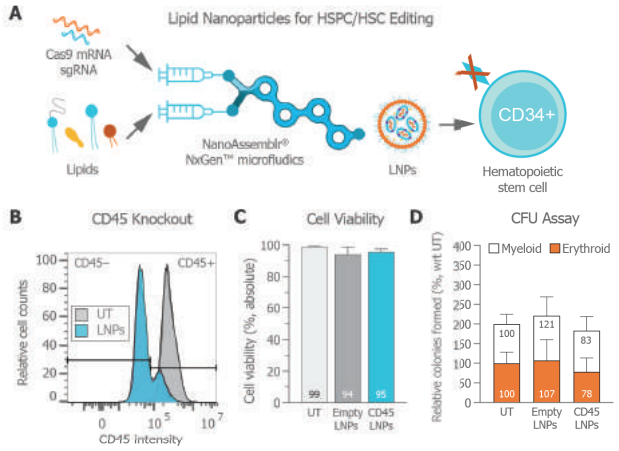


Figure 1. A) Lipids, Cas9 mRNA, and sgRNA were combined using a commercial microfluidic platform. Resulting CRISPR-LNPs were added to purified, human, CD34+ hematopoietic stem cells. **B)** CD45 CRISPR LNP treated cells show high gene knockout, as seen with flow cytometry. CD45 surface intensity rapidly diminishes, while maintained on untreated (UT) cells, one experiment shown. **C)** Absolute cell viabilities as determined with flow cytometry, UT, empty LNP and CRISPR LNP treated shown, n>4 experiments. **D)** Colony forming unit assay was conducted on untreated, empty LNP, or CD45 targeted CRISPR-LNP treated cells, n=4 unique experiments.

1518 Comparison of Cardiac Specific Promoters to Liver-Specific miRNA Targets to Maximize Cardiac *vs* Liver Expression Following Intravenous AAVrh.10-Mediated Cardiac Gene Therapy

Abhishek Bose, Neil R. Hackett, Nadir Khan-Yusufzai, Katie M. Stiles, Ronald G. Crystal

Department of Genetic Medicine, Weill Cornell Medicine, New York, NY

Intravenous (IV) administration of a cardiotropic AAV vector is the simplest and most effective strategy to deliver a gene to the myocardium for the treatment of hereditary cardiac disease. The challenge in using the IV route is that a substantial proportion of AAV vectors distribute to the liver, resulting in high liver expression with risks of liver toxicity. One approach to optimizing cardiac to liver expression levels following IV AAV administration is to modify the expression cassette to favor cardiac while minimizing liver expression. To identify the optimal strategy to enhance cardiac *vs* liver expression levels, we used the cardiotropic AAVrh.10 capsid to assess cardiac *vs* liver expression with cardiac-specific promoters *vs* the CAG highly active ubiquitous promoter driving an expression cassette with liver-specific expression-suppressing miRNA targets. Cardiac-specific promoters (TNNI3, PLN, ANKRD1, TNNT2 and MYOZ2) driving FXN were compared to expression cassettes with the CAG promoter driving FXN plus 3' liver-specific miRNA targets (miR122, 148, 192 and 194). FXN is an autosomal gene product targeted to mitochondria. GAA repeats in intron 1 of the FXN gene are responsible for Friedreich's ataxia, an autosomal recessive disorder characterized by neurologic and cardiac disease, with the cardiac disease responsible for two-thirds of deaths. Following screening *in vitro* using the HuH7 liver and A16 cardiac cells lines, cardiac-specific promoters (TNNI3, PLN, ANKRD1, TNNT2 and MYOZ2) driving FXN were compared to expression cassettes with the CAG promoter driving FXN plus 3' liver-specific miRNA targets (miR122, 148, 192 and 194). Using a human specific ELISA to assess cardiac and liver levels of human FXN protein as the outcome parameters, AAVrh.10 vectors with cardiac-specific promoters *vs* the CAG promoter with liver suppression miRNA targets were administered IV to male C57Bl/6 mice (age 6 to 7 weeks, $4x10^{12}$ gc/kg, assessed 4 weeks after administration) compared to AAVrh.10CAGhFXN as the 100% benchmark. Analysis of human FXN levels in the heart and liver of the mice 4 weeks after administration demonstrated that for the cardiac-specific promoters, the cardiac levels (compared to the CAG promoter as 100%) were 2.49% (TNNI3), 1.19% (PLN), 1.94% (ANKRD1), 9.42% (TNNT2) and 0.02% (MYOZ2). The liver FXN levels were all <0.003% of the liver expression with the CAG promoter. Thus, with the cardiac-specific promoters, there was high cardiac to liver specificity, but at the price that the cardiac levels were all <10% of cardiac levels mediated by the CAG promoter. In contrast, with the CAG promoter with liver-specific miRNA targets in the expression cassette, the cardiac levels (compared to the CAG promoter without the miRNA targets as 100%) were 27.7% (miR122), 30.1% (miR148), >100% (miR192), and 47.0% (miR194) and the liver levels were 8.6% (miR122), 26.7% (miR148), 92.8% (miR192) and 11.6% (miR194). With the highly active constitutive CAG promoter plus liver-specific miRNA targets, although the liver suppression was less than with the cardiac-specific promoter, cardiac expression was much higher. With the caveat that the data is from one transgene, one mouse strain and pending testing in larger animals, the use of a highly active constitutive promoter together with liver-specific miRNA targets, particularly miR194, enables high cardiac expression while limiting liver expression, providing an alternative to cardiac-specific promoters that may require higher doses to achieve the same cardiac expression levels.

1519 Pancreatic Cancer Gene Therapy with Liposome-Processed Midkine Gene Promoter-Introduced Oncolytic Adenovirus

Rei Okada, Katsuyuki Hamada, Teruki Yamakawa, Youji Kajiwara, Hideaki Shimada

Toho University Graduate School of Medicine, Ota-ku, Japan

Pancreatic cancer is increasing every year and will be the second leading cause of death in 20 years. Because the number of patients with the disease is almost equal to the number of deaths, it is considered to be a representative of refractory cancers. The 5-year survival rate of pancreatic cancer is reported to be 10%, and even in the early stages, stages I-II, it is about 20-40%. Attempts have been made to improve surgical therapy, chemotherapy, radiation therapy, immunotherapy, and other therapies, but they have not improved the prognosis. Therefore, the development of novel therapeutic methods is expected. About 50 protocols of gene therapy for pancreatic cancer have been tested in clinical trials, using various viral vectors such as adenovirus, AAV, retrovirus, lentivirus, herpes virus, poxvirus, SV40 virus, and others. It is administered intratumorally, intraperitoneally, intravenously, or subcutaneously, often in combination with immunotherapy, radiation therapy, or chemotherapy, but effective results have not yet been reported. We cloned a midkine promoter with pan-tumor-specific activity and generated an oncolytic adenovirus, AdE3-midkine, transfected with this promoter. AdE3-midkine shows antitumor activity in the absence of anti-adenovirus antibody, but does not show antitumor effect in the presence of anti-adenovirus antibody due to suppression of infection. When carrier cells infected with oncolytic adenovirus are used, adenoviral infection is established even in the presence of anti-adenovirus antibody, and it shows antitumor effect, but clinical application is difficult due to severe side effects such as DIC due to acute cell disruption syndrome of carrier cells caused by the cytolytic action of oncolytic adenovirus. For this reason, we developed a new DOPE/DOTAP/EPC liposome system and processed it to coat oncolytic adenovirus, enabling oncolytic adenovirus infection even in the presence of anti-adenovirus antibodies. Mice not preimmunized with adenovirus showed no anti-tumor effect, but preimmunized mice showed 30% complete tumor regression with AdE3-midkine alone and 50% complete tumor regression with AdE3-midkine and Ad-mGM-CSF, indicating a strong anti-tumor effect by anti-adenoviral CTL induction. These results suggest that liposome-processed oncolytic adenovirus may be an effective treatment for refractory pancreatic cancer.

1520 An Efficient Approach to Check Accuracy of Viral Copy Number Assay in Droplet Digital PCR

Raymond Wu[1], Frank Luh[1], Jeff Masten[2], Yun Yen[1]
[1]Covina Discovery Center, Theragent Inc., Covina, CA,[2]Theragent Inc., Arcadia, CA

Viral Copy Number (VCN) assay is a critical assay in cell and gene therapy because it is used to monitor toxicity, pharmacokinetics and durability of virus modified cell therapy products. However, the assay needs to be validated for its accuracy before it can be used in clinical settings. Here, we describe an approach to check the accuracy of this assay by using a commercially available synthetic DNA called gBlocks. gBlocks are traditionally used as positive controls for quantitative PCR and Next Generation Sequencing assays. We synthesized a gBlock containing the primer and probe binding sites of Woodchuck Hepatitis Virus Posttranscriptional Regulatory Element (*WPRE*) and Ribonuclease P Protein subunit p30 (*RPP30*). The two DNA fragments are connected by Hind III endonuclease cutting site. *WPRE* is commonly included in many lentiviral vectors. *RPP30* is commonly used as a housekeeping gene in droplet digital PCR (ddPCR) because it is validated to have two copies in mammalian cells. *WPRE* and *RPP30* assays are also commonly used in ddPCR to measure viral copy number integrated in cells after lentivirus infection. Using a multiplex *WPRE/RPP30* ddPCR assay, we amplified *WPRE* and *RPP30* from the *WPRE-RPP30* gBlock with the same efficiency. Therefore, the copy number generated from *WPRE*/*RPP30* is approximately 2 regardless of input number of DNA. The copy number of *WPRE* and *RPP30* is accurately detected as low as 4.38 copies of the input gBlock number. In conclusion, gBlocks can be used as a quality control material to monitor the VCN assay and the approach can be robustly applied to other Chimeric Antigen Receptor (CAR) specific VCN assays.

1521 Structural Basis for BBB Crossing by 9P31 & 9P36 Recombinant AAVs through the Novel Receptor Carbonic Anhydrase 4

Seongmin Jang, Tyler Brittain, Timothy Shay, Viviana Gradinaru
California Institute of Technology, Pasadena, CA

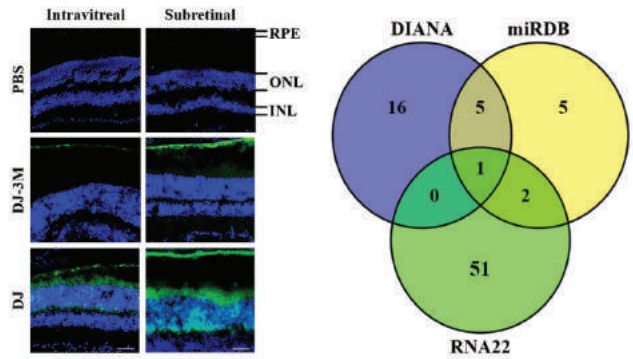
Due to its ability to cross the blood-brain barrier (BBB), adeno-associated virus serotype 9 (AAV9) has been studied as a potential gene delivery vehicle for the treatment of brain diseases. Engineering efforts have yielded multiple brain tropism-enhanced AAV9 variants, such as PHP.eB from *Chan et al, 2017* and 9P31 and 9P36 from *Nonnenmacher et al, 2021*. All three capsids have a 7-amino-acid peptide insertion at the same position of the VR-VIII loop. PHP.eB and 9P36 also have point mutations in neighboring residues. We recently reported that 9P31 & 9P36 are distinct from PHP.eB in that they do not bind the murine BBB receptor LY6A. Instead, we identified carbonic anhydrase 4 (CA4) as a novel receptor for 9P31 and 9P36 to cross the BBB (*Shay et al, 2023*). However, the detailed molecular interactions remain unknown. Here we show by pull-down assays that CA4 selectively binds 9P31 but not PHP.eB, suggesting that CA4-mediated BBB crossing is a unique property of 9P31/9P36. We also report cryo-electron microscopy (cryo-EM) single-particle structures of 9P31 and 9P36 with resolutions of 2.24 and 2.03 Å, respectively. Both structures show more order in the C-terminal residues of the 7-mer protrusion than the N-terminal. We also solved another 2.9 Å cryo-EM structure of 9P31 in complex with mouse CA4. Unfortunately, we could not resolve CA4 electron density in this structure, but we did observe a conformational change in the 9P31 7-mer induced by CA4: the C-terminus became more ordered. Our three cryo-EM structures, together with our pull-down data and the conserved sequence of the C-terminal part of the VR-VIII loop, suggest that this C-terminal region of the 7-mer loop is responsible for recognizing and binding CA4.

1523 Knocking Down the Endogenous Bicistronic *mfrp* and *ctrp5* Transcript Benefits the Gene Therapy for MFRP Deficiency-Mediated Retinal Degeneration

Qing Yun Zheng[1], Xiao Tian[1], Ming Yang[1], Heng Bin Yang[1], Qing Ling Lan Zhou[1], Letong Liang[1], Guo Tong Xu[2], Hong Yan Chen[1], Chen Ling[1], Da Ru Lu[1]
[1]Fudan University, Shanghai, China,[2]Tongji University, Shanghai, China

The membrane frizzled-related protein (*mfrp*) gene encodes a type II transmembrane protein predominantly in the retinal pigment epithelium (RPE) and ciliary body. A number of MFRP mutations have now been described in human, which are associated with autosomal recessive retinitis pigmentosa (RP). C1-tumor necrosis factor related protein 5 (CTRP5) is a secreted protein involving in cellular adhesion and fatty acid metabolism, whose mutation causes dominant late-onset retinal degeneration. The *mfrp* and *ctrp5* genes are expressed as a bicistronic transcript in the RPE cells. Both are associated with retinal degeneration in the eye. However, the crosstalk between these two genes and the functional role of CTRP5 in AAV-based treatment of retinitis pigmentosa that was caused by MFRP deficiency remain controversial. Here, we discovered a microRNA-based negative feedback loop to maintain normal expression level of the bicistronic *mfrp* and *ctrp5* transcript. Specifically, overexpressing MFRP significantly enhanced miR-149-3p level in the cultured cells, which in turn reduced the level of bicistronic *mfrp* and *ctrp5* transcript.First, we found the bicistronic *mfrp* and *ctrp5* transcript was significantly increased in the rd6 mice, a preclinical model of RP. We observed that when MFRP was overexpressed, there is a significant reduction in the bicistronic *mfrp* and *ctrp5* transcript both *in vitro* and *in vivo*. Next, we would like to explore the potential mechanism of MFRP's inhibitory effect on the bicistronic *mfrp* and *ctrp5* transcript. The bioinformatics analysis was conducted to predict miRNAs that may target the bicistronic *mfrp* and *ctrp5* transcript. (Fig.1) Among all the potential miRNAs, miR-149-3p was most significantly reduced in the RPE-choroid complexes of rd6 mouse eyes, compared to those of the WT mouse eyes. Overexpressing MFRP in the N2A cells significantly increased the levels of endogenous miR-149-3p. We further identified an evolutionally conserved miR-149-3p binding site in the 3'UTR of *mfrp* gene. It mediated significant decrease in the expression of upstream, cloned firefly luciferase gene upon transfection with miR-149-3p mimics *in vitro*. Thus, we concluded that MFRP inhibited the bicistronic *mfrp* and *ctrp5* transcript through miR-149-3p.More importantly, we applied our findings to AAV-based treatment of retinitis pigmentosa. We reported a capsid-modified rAAVDJ-3M vector capable of robustly and specifically transducing the RPE cells following subretinal delivery to mouse eyes. Compared to the parental vector, the modified vector induced fewer immune

responses, in terms of generating serum anti-rAAV antibodies and recruiting microglial infiltrations. (Fig.1) We observed that knocking down the bicistronic mfrp and ctrp5 transcript *in vivo* using rAAVDJ-3M-shRNA4 partially rescues rod- and cone-mediated ERG function in the rd6 mice. Furthermore, simultaneously overexpressing MFRP and knocking down the bicistronic *mfrp* and *ctrp5* transcript using rAAVDJ-3M-*mfrp*-shRNA4 provided long-term vision rescue in the *rd6* mice. Our studies provide not only new insights into the function of MFRP, but also a new therapeutic strategy for treating the MFRP-associated ocular diseases.



1524 CRISPR-Cas9-Based Gene Therapy for Treatment of IL2RA Deficiency

Alvin Ha[1,2], Brian R. Shy[1,2], Luis Acevedo[1], Weihong Liu[1], Sreenivasan Paruthiyil[1], Gisela Marrero-Rivera[1], Theodore L. Roth[3], Jason Catanzaro[4], Jeffrey A. Bluestone[5], Qizhi Tang[6], Kevan Herold[7], Alexander Marson[2], Jonathan H. Esensten[1]

[1]Laboratory Medicine, University of California - San Francisco, San Francisco, CA,[2]Gladstone-UCSF Institute of Genomic Immunology, Gladstone Institutes, San Francisco, CA,[3]Medical Scientist Training Program, University of California, San Francisco, San Francisco, CA,[4]Department of Pediatric Pulmonology, Allergy, Immunology & Sleep Medicine, Yale School of Medicine, New Haven, CT,[5]Diabetes Center, UCSF, San Francisco, CA,[6]Department of Surgery, University of California - San Francisco, San Francisco, CA,[7]Department of Immunobiology and Internal Medicine, Yale School of Medicine, New Haven, CT

Interleukin-2 (IL-2) plays a critical role in the development and function of regulatory T cells (Tregs) which are characterized by constitutive surface expression of the high-affinity IL-2 receptor alpha subunit (*IL2RA* or CD25). We have previously identified a family carrying compound heterozygous loss-of-function mutations in *IL2RA* (c.530 G>A, c.800delA) that disrupt Treg function, resulting in a range of autoimmune manifestations. One sibling in this family is more severely affected with an autoimmune pancytopenia (autoimmune hemolytic anemia, immune thrombocytopenia, and autoimmune neutropenia) requiring more aggressive clinical management. Current definitive treatment options for this patient are limited to allogeneic hematopoietic stem cell transplant (HSCT), which is associated with significant morbidity and mortality. As a potential alternative, we have developed an autologous Treg therapy providing a targeted correction of the pathogenic c.530 allele using CRISPR-Cas9 mediated homology directed repair (HDR). Here, we demonstrate an *ex vivo* manufacturing process to isolate, correct, purify, and expand *IL2RA* gene-corrected Tregs (gcTregs). Full clinical scale qualification runs were performed under current Good Manufacturing Practice (cGMP) within the UCSF Human Islet and Cellular Transplantation Facility (HICTF) with cells from a healthy donor and from the potential subject. Gene correction efficiencies were >50% following electroporation with Cas9/gRNA ribonuclear proteins (RNP) and a short DNA template encoding the wild-type IL2RA sequence. The products were sorted on IL2RA to obtain a pure population of IL2RA-corrected Tregs (>90% FOXP3$^+$, >95% IL2RA$^+$). Both qualification runs met all proposed release criteria, demonstrated Treg identity comparable to healthy donor Tregs by flow cytometry and Treg Specific Demethylated Region (TSDR) analysis, and effectively suppressed CD8$^+$ T cell proliferation in co-culture assays. In summary, we demonstrate an efficient process to manufacture gcTregs that could provide an effective treatment for patient's with the IL2RA c.530A mutation and serve as a foundation for alternative targeted gene corrections for inherited immune disorders.

1525 Role of Dendritic Cell Type 1 in AAV Mediated Antigen-Specific Immunity

Marcos Tejero[1], Ester Molina[1], Hisae Kuoch[1], Ozgun Firat Duzenli[1], George Aslanidi[1,2,3]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]Masonic Cancer Center, University of Mimnesota, Minneapolis, MN,[3]Institute Molecular Virology, University of Minnesota, Minneapolis, MN

Adeno-associated virus (AAV) is a naturally occurring human/animal virus. The recombinant vectors based on these viruses have been shown to be safe for human gene therapy and generally gene transfer applications since there are no known diseases related to their infection. AAV vectors are also used for immunomodulation and the development of vaccines against infectious diseases and cancers. In order to be used for therapies that modulate the host´s immune system response and eliminate cancer cells, AAV vectors need to deliver target tumor antigens to dendritic cells (DCs). DCs are professional antigen-presenting cells located abroad the body and are critical for the activation of the adaptive and the innate immune response. There are two main populations of DCs, cDC type 1 (cDC1) and cDC type 2 (cDC2). The exact mechanism of interaction between AAV vectors with different subsets of DCs is not well understood. We previously injected capsid-optimized AAV6-S663V, expressing the green fluorescent protein in mice biceps femoris muscle and showed that these vectors target local DCs (CD11c$^+$/MHC II$^+$) that later migrate to draining lymph nodes. We further showed that AAV infection activates (CD40$^+$/CCR7$^+$) both DC1 (CD11c$^+$/MHC-II$^+$/PDCA$^-$/XCR-1$^+$/CD11b$^-$) and DC2 (CD11c$^+$/MHC-II$^+$/PDCA$^-$/XCR-1$^-$/CD11b$^+$) cells. Additionally, AAV6-S663V carrying either ovalbumin (OVA) or tyrosinase-related protein 1 (TRP1) genes merged with MHC class I molecule-trafficking signals, dramatically increases both CD4$^+$ and CD8$^+$ T cells expansion that developed 2 weeks post intramuscular administration of 1x10^{10} vg in C57BL6 mice. Results were confirmed by both flow cytometry for CD8$^+$ T cells with OVA-specific MHC I tetramers (SIINFEKL) or TRP1-specific MHC I dextramers (TAPDNLGYA) respectively, and by IFN-γ ELISPOT assays. We further observed that optimized AAV-TRP-1 delivery via intramuscular injection can elicit an immune response that is able to dramatically reduce lung metastasis by B16F10 melanoma cells spread by intravenous injection. To study the role of

cDC1 in AAV-expressing tumor antigen-based vaccination we used C57BL/6-*Irf8*^{em1Kmm} (Irf8$^{-/-}$) mice lacking cDC1 with no defects in other DC lineages. When comparing the immune response to optimized AAV-delivered TRP-1 antigen Irf8$^{-/-}$ and wild type (wt) C57BL6 mice developed a similar number of IFN-γ produced CD8^{+} T cells. Moreover, AAV-TRP-1 vaccinated Ir8$^{-/-}$ mice displayed significantly reduced lung metastasis after B16F10 melanoma cell administration with no differences compared with wt C57BL6 mice. Altogether our preliminary data suggest that cDC1 cells are not essential for the development self-antigen specific CD8^{+} T cells. However further experiments using alternative animal models, and antibody-based depletion of different effector and antigen-presenting cells are necessary to support our conclusion.

1526 The Dirtier the Better: Viral Pre-Existing Immunity a Friend of Oncolytic Viruses Based Therapy

Sara Feola[1], Salvatore Russo[1], Manlio Fusciello[1], Jacopo Chiaro[2], Michaela Feodoroff[1], Firas Hamdan[3], Gabriella Antignani[1], Alba Arbiol[1], Tapani Viitala[1], Claire Stratchan[1], Mikaela Gronholm[1], Vincenzo Cerullo[3]

[1]Pharmacy, University of Helsinki, Helsinki, Finland,[2]University of Helinski, Helinski, Finland,[3]University of Helsinki, Helsinki, Finland

Oncolytic vaccines, as highly immunogenic platforms, re-gained momentum leading to public and private investments. Indeed, oncolytic viruses propagate and kill selectively cancer cells. Simultaneously, the virus infection acts as adjuvant recruiting anti-tumor immunotherapy effectors within the cancer bed. Historically oncolytic viruses have been co-developed together with their non-replicating counterpart viral vectors, that are used for gene therapy and delivery. For classical gene therapy approaches, a high level of tissue target transduction is needed hence the presence of a pre-existing anti-viral immune response, diminishes the efficacy of that vector, hampering the entire clinical protocol. On the other hand, in the field of oncolytic viruses, and specifically oncolytic immunotherapy, it is still not clear whether pre-existing immunity to the virus is deleterious or efficacious; this aspect of the oncolytic viruses needs to be elucidated. Here, we addressed the role of viral pre-existing immunity upon treatment with a platform previously developed in our lab named PeptiCRAd. This latter consists of an oncolytic adenovirus decorated with tumor MHC-I restricted peptides. First, we investigated the impact of viral neutralizing antibodies on PeptiCRAd uptake in APC (DCs and macrophages). To this end, we used SIINFEKL as a model and we pulsed primary DCs or macrophages either with PeptiCRAd-SIINFEKL or with PeptiCRAd-SIINFEKL pre-incubated with naïve (Naïve-PeptiCRAd) or adeno positive (PEI-PeptiCRAd) murine serum. In presence of PEI-PeptiCRAd-SIINFEKL, we observed an enhanced presentation of H2Kb bound SIINFEKL and CD86 in the macrophagic population, indicating that the immune adenoviral serum directed PeptiCRAd-SIINFEKL internalization toward cross-antigen presentation pathway in an immunogenic fashion. As we sought to better characterize the uptake of PEI-PeptiCRAd in macrophages, we adopted Surface Plasmon Resonance (SPR) method to analyze the intake of PEI-PeptiCRAd in RAW 264.7, a murine macrophage cell line. Confirming our previous observations, PEI-PeptiCRAd showed enhanced interaction with RAW 264.7 in comparison to Naïve-PeptiCRAd. Next, we wanted to examine the anti-tumor effect of adenoviral pre-existing immunity *in vivo* in three different immunological murine cancer models. For these studies, we selected the poor immunogenic melanoma model B16.OVA, the immunogenic colon cancer model CT26, and the immunosuppressive triple-negative breast cancer model 4T1. As mice are naïve to adenoviral infections, to generate adenoviral pre-existing immunity, we subcutaneously injected mice with adenovirus. Before engrafting the tumors, we confirmed the presence of an anti-viral immune response by the detection of anti-adenovirus IgG in the serum of pre-immunized mice and by anti-adenoviral T cell in a ELISPOT IFN-γ assay . A cohort of not-adeno preimmunized mice (naïve mice) was used as a control as well. In the poorly immunogenic B16.OVA model, the tumor growth was delayed in both Naïve and PEI mice upon PeptiCRAd treatment either using the model peptide SIINFEKL or the more clinically relevant peptide TRP2. Indeed, both flow cytometry and ELISPOT IFN-γ analysis showed the generation of antigen-specific T cells in mice treated with PeptiCRAd to the same extent in naïve and PEI mice. In contrast, in the immunogenic tumor model CT26, tumor growth control was observed in Naïve and to a better degree in PEI mice. In this latter, the presence of antigen-specific T cells was enhanced in presence of vector pre-existing immunity. Currently, 4T1 tumor model is under investigation.

1527 CRISPR Screen to Identification the Role of Tumor Microenvironment Oncometabolites on Natural Killer Cell Activity Against Solid Tumors

Xinyu Wu

Purdue University, West Lafayette, IN

Research Summary: - Background: Natural killer (NK) cells are part of the innate immune system, and possess high cytolytic activity against tumor cells, along with the ability to secrete cytokines and chemokines. However, solid tumors have been largely resistant to attack by NK cells, owing to unfavorable interactions between immune cells and tumors driven by an immunosuppressive tumor microenvironment (TME). The TME of solid tumors is characterized by elevated levels of oncometabolites. However, how their presence affects the activity of NK cells against solid tumors is not known. Among oncometabolites, we have found that 5'-Deoxy-5'-methylthioadenosine (MTA), an adenosine receptor agonist, and succinic acid, one of the metabolites of the TCA cycle, can alter NK cell behavior in the TME via different mechanisms. To understand how cancer cells respond to NK cell activity in an oncometabolite-rich environment, we studied their effects, and corresponding responses, via CRISPR screening of NK cell and solid tumor systems. - Methods and Results: NK cells were isolated from lung cancer patients and healthy adult donors. To study the effect of oncometabolites, NK cells were treated with various concentrations of oncometabolites for 24 hours, then the viability of NK cells was measured via the CCK8 assay. Lung adenocarcinoma (A549) cells were then cocultured with oncometabolite-treated NK cells in the absence or presence of oncometabolites to measure the cytotoxicity and IFN-γ production.Separately, oncometabolite-treated NK cells were used in a co-culture setting to identify drivers of the response of cancer cells to NK-mediated killing via a genome-based CRISPR screen. A549 cells were transduced with the CRISPR pooled

library and positively selected with puromycin. After co-culture with NK cells, the DNA genome was isolated and sequenced. - Conclusions: Our data showed that metabolites affect NK cell-killing capacity. Interestingly, we found that oncometabolites heterogeneously modulate the killing ability of NK cells, suggesting that contexts- and receptor-specific activation - such as the continued presence of cytokines and metabolites - drive NK cell responses to metabolic factors in the TME. Among the tested oncometabolites, MTA could drastically decrease IFN-γ levels while increasing NK cell cytotoxicity, without affecting the viability. Conversely, succinic acid showed significantly detrimental effects on NK cell viability while increasing their killing ability. We also identified genetic markers of the response of cancer cells to killing by NK cells in the presence of oncometabolites. Taken together, our data show divergent and heterogeneous effects of oncometabolites present in the TME and suggest possible genetic targets that can promote NK cell activation in these contexts.

1528 Humanized Chimeric AAV Antibodies for the Detection of Intact AAV Capsids

Lisa Mutz, Christina Querfurth, Klaus-Ingmar Pfrepper, Caroline Odenwald, Dana Holzinger, Maik Lander

PROGEN Biotechnik GmbH, Heidelberg, Germany

Recombinant adeno-associated virus (AAV) vectors have become leading tools for viral gene therapy. Alongside the many advantages, like its apathogenic nature, there are some concerns about the safety and efficiency of AAV-based gene delivery into human cells. Depending on the AAV serotype, many humans in the general population have developed antibodies against AAV as a result of naturally acquired infections. Thus, serum antibodies against many of the wild-type AAV capsid proteins can be found in a significant proportion of the population. Intriguingly, pre-existing immunity to AAV might affect efficiency and safety of the gene transfer using AAV vectors. While the use of a high dose of AAV particles might lead to unwanted immune reactions that might put the patient at risk, the use of a low dose might fail to elicit the desired therapeutic effect. Finding the right dose without causing severe side effects but ensuring efficiency of the therapy still is a major challenge in every therapeutic approach. It is an even greater challenge in the area of virus-based gene therapy due to the limitation of a single vector application to each patient. Therefore, testing for pre-existing AAV antibodies in patient sera remains an indispensable step for the inclusion of patients into gene therapy programs. To develop reliable and reproducible AAV serology assays for the evaluation of patient groups, positive controls are crucial. For this purpose, well-characterized sero-positive samples or purified human antibodies that are verified to bind or even neutralize the corresponding AAV serotype are valuable controls. To provide this suitable and fully characterized positive control for serological analysis of patient sera, we developed recombinant humanized chimeric AAV antibodies against a number of different AAV serotypes, including AAV1, 2, 3, 5, 6, 7, 8, 9, rh10, and rh74. Our new recombinant humanized chimeric AAV antibodies have been developed based on our exclusive portfolio of neutralizing anti-AAV mouse monoclonal antibodies. The antibodies have identical sequences to our conventional mouse AAV antibodies (e.g. ADK1a, A20, ADK5b, ADK8, ADK9), but contain a humanized Fc region to allow comparability with antibodies from patient sera. Thus, these antibodies can be detected in AAV serology assays based on an anti-human secondary antibody system. Here, we show characterization data of our new humanized chimeric AAV antibodies, including cross-reactivity, stability and neutralization. There is high similarity regarding cross-reactivity when compared with our conventional mouse monoclonal parental clones. The applications of these antibodies include dot blot analyses, neutralization assays as well as ELISA.

1529 The Effect of Cell Density on the Plasmid Utilization for the Production of Adeno-Associated Virus via the Triple-Transfection Method

Brian Ladd, Véronique Chotteau

KTH, Stockholm, Sweden

Adeno-associated virus (AAV) is one of the leading vectors in the field of gene therapy with several approved treatments currently on the market. Production of AAV via the triple-transfection method is highly flexible with the capsid and gene-of-interest (GOI) being readily exchanged, facilitating rapid development. This method, however requires large quantities of high-grade plasmid DNA. To facilitate scale up and reduce the cost-of-goods, the utilization of plasmid DNA should be increased. We have previously devolved a process using adherent HEK293T cells on microcarriers to take advantage of the higher cell specific productivity seen in adherent cells and the scalability of microcarriers. However, this process was limited in the maximum cell density achievable due to several reasons, primarily shear stress. This limitation is not present in suspension cells with cell densities in excess of 80 x 10^6 cells/mL being achieved. The increase in cell density and shift to a perfusion-based process requires the screening of a large number of conditions for transfection, necessitating a scale down model.In this study a process intensification strategy was used to increase the transfection efficiency and product titer of AAV9 in suspension HEK293T cells, with a view for continuous production. A scale down model system, based on maximum power input, was used together with pseudo-perfusion to closely mimic the conditions in a stirred tank bioreactor in continuous production. Cell specific rates of glucose, glutamine, lactate, LDH, and ammonia were measured during cultivations. The AAV9 vector with green fluorescent protein (GFP) as the GOI was produced in suspension HEK293T cells via the triple-transfection method with polyethylenimine (PEI) as the transfection reagent. The impact of key transfection parameters on transfection efficiency and AAV9 titer was evaluated using flow cytometry, cell-based assays, ELISA, and qPCR. The scale down model showed a high degree of similarity to the stirred tank bioreactor with similar growth and cell specific rates in the measured metabolites being observed. Increasing cell density while maintaining a constant cell-to-DNA ratio greatly improved transfection efficiency and AAV9 production. The results of this study show that intensification of the transfection step in AAV production will increase the efficiency to which the plasmid DNA is used, thus lowering the cost-of-goods.

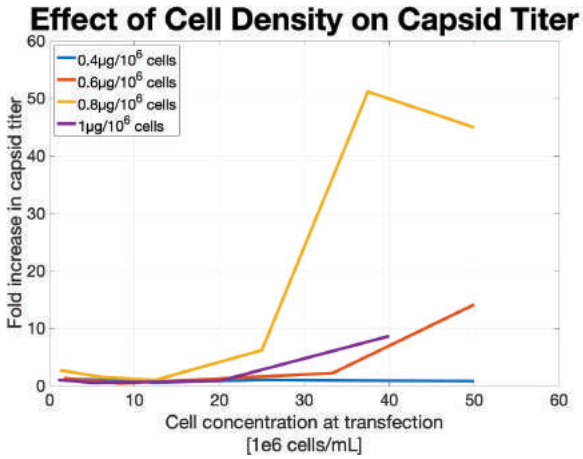


Figure 1: The effect of cell density at the time of transfection on the relative capsid titer of rAAV9 production through the triple transfection method.

1530 How Modifications of AAV Inverted-Terminal Repeats (ITRs) and *cis*-Packaging Size Impacts Vector Production

Kelly Geosits[1], Jacob Hewes[1], Ngan Trinh[1], Khan Umaer[1], Srivanya Tummala[1], Marguerite Campbell[1], Alexei Saveliev[2], Brian Tomkowicz[1]

[1]Viral Vector Research & Development, Center for Breakthrough Medicines, King Of Prussia, PA,[2]Next Generation Sequencing, Center for Breakthrough Medicines, King of Prussia, PA

The seminal observations that AAV2 could be rescued and replicated from proviral plasmids, following transfection into human cells, with necessary adenoviral helper functions (provided in plasmid or viral format) laid the foundation for the development of recombinant of AAV (rAAV) vectors. The discovery that the AAV ITRs were the only sequences required in *cis* for rescue, replication, and packaging of viral genomes, coupled to the observations that AAV vectors containing the AAV2 ITRs could be cross packaged with capsids from multiple AAV serotypes has simplified the use and manufacturability of AAV gene therapies using AAV2 ITRs. These GC-rich segments of DNA are 145 nucleotides long, with the first 125 bases able to form a T-shaped hairpin structure, which flanks the entire AAV genome and provides critical recognition sequences that are required for directing the AAV rep and host cell proteins to replicate and encapsidate the viral DNA into pre-assembled AAV capsids. Thus far, these short sequences of DNA have proven to be particularly problematic during vector engineering, plasmid manufacturing and scale up, predominantly due to the inherent instability of replicating these features in bacterial systems. While the use of traditional Sanger-based methods have been relatively insufficient at identifying low-level mutations within ITRs, it is only now, that newer, more sensitive, Next-Generation Sequencing technologies, have quickly been implemented as the standard quality control measure. With ever increasing scrutiny by regulatory agencies, maintaining ITR integrity is paramount from a clinical standpoint when consistent purity and potency are vital for effective gene therapies. Towards that end, we examined how ITR integrity and packaged genome sizes impacts the production of AAV vectors. Using widely established AKTA-based chromatography methods we demonstrate that undersized genomes as well as mutated ITRs significantly alter the types of virus particles produced (empty, full, partial, other). Moreover, we have developed a proprietary pCBM-ITR-containing entry vector that has intact ITRs, as well as a GC-less (<40%) tract flanking the ITR region for improved stability and overall performance. Using the triple-transfection method of AAV production, coupled to a universal two-step AKTA-based affinity and anion chromatography, we show how perturbations in ITRs impact the yields and distribution of AAV viruses produced.

1531 Developing Immunocompetent Models to Evaluate B7-H3-CAR T Cells for Acute Myeloid Leukemia

Sarah E. Moore[1], Jaquelyn T. Zoine[1], Chris Nevitt[1], Phuong Nguyen[1], Carla O'Reilly[1], Ilaria Iacobucci[2], Nicole L. Michmerhuizen[2], Juan M. Barajas[2], Sherif Abdelhamed[2], Dalia Haydar[1], Deanna M. Langfitt[1], Christopher DeRenzo[1], Charles G. Mullighan[2], Giedre Krenciute[1], Jeffery M. Klco[2], M. Paulina Velasquez[1]

[1]Bone Marrow Transplantation & Cellular Therapy, St. Jude Children's Research Hospital, Memphis, TN,[2]Pathology, St. Jude Children's Research Hospital, Memphis, TN

Background: Targeting acute myeloid leukemia (AML) with chimeric antigen receptor (CAR) T cells is challenging due to high overlap of antigen expression on hematopoietic progenitor cells (HPCs) and leukemia cells and an immunosuppressive tumor microenvironment (TME). B7-H3, a coreceptor in the B7 family of immune checkpoint molecules, is an attractive target for immunotherapy as it is overexpressed in several subsets of pediatric AML (e.g., KMT2Ar, GLIS fusions) but is not found on normal HPCs. Although B7-H3-CAR T cells demonstrate anti-AML activity in xenograft models, these models lack an intact host immune system and representative AML TME required to properly assess CAR T cell anti-AML activity. To address this need, our group developed novel AML immunocompetent models where we demonstrate that mouse B7-H3 (mB7-H3)-CAR T cells are safe, with potent anti-AML activity *in vitro* and *in vivo*. **Methods/Results:** To evaluate the efficacy of mB7-H3-CAR cells for AML, we generated two immunocompetent models. In the first model we overexpressed mB7-H3 on the cell surface of AML cell line C1498 (C1498$^{mB7\text{-}H3+}$). The second model required determining natural expression of mB7-H3 on virally induced NUP98::KDM5A leukemias (N=4). We measured leukemia engraftment in C57BL/6 via bioluminescence in the C1498$^{mB7\text{-}H3+}$ model or flow cytometry in the NUP98::KDM5A model. We confirmed stable expression of mB7-H3 in the bone marrow and spleen of mice post tumor engraftment. Next, we generated mB7-H3-CAR T cells with or without co-expression of full length 41BB ligand (41BBL) by retroviral transduction of mouse splenocytes. We evaluated anti-AML activity *in vitro* using C1498$^{mB7\text{-}H3+}$ cells and noted robust, antigen-specific cytotoxicity and significant IFN-γ and IL-2 secretion elicited by mB7-H3- and 41BBL.mB7-H3-CARs ($p<0.0001$; N=4). We also show that co-expression of 41BBL allows 41BBL.mB7-H3-CAR T cells to sustain *in vitro* antitumor activity upon serial stimulation longer than mB7-H3-CAR T cells alone (N=4). To test *in vivo* antitumor activity, mice were engrafted with 1e6 NUP98:KDM5A

cells. A single of infusion of 3e6 mB7-H3-CAR T cells demonstrated significant anti-AML activity ($p<0.001$) when compared to control-CAR T cells, resulting in a survival advantage ($p<0.01$, N=5/group). To evaluate safety of mB7-H3-CAR T cells, we injected non-tumor bearing C57BL/6 mice with a single infusion of 1e7 CAR T cells (either mB7-H3- or control-CAR T cells; N=5) generated from transgenic luciferase mice. Mice were monitored via daily bioluminescence imaging for 10 days. Neither mB7-H3- nor control-CAR T cells demonstrated significant tumor-independent expansion *in vivo*. We harvested bone marrow 10 days post T cell injection. Flow cytometry analysis and colony formation assays reveal that mB7-H3-CAR T cells do not significantly impact HPCs present within the bone marrow nor their ability to proliferate and differentiate (N=3). **Conclusions:** We demonstrate that mB7-H3-CAR T cells have potent anti-AML activity *in vitro* and *in vivo,* but do not result in non-specific expansion *in vivo.* Further work will utilize our novel AML models to study how both cellular interactions and secreted factors produced within the TME impact CAR T cell functionality. These findings will inform strategies to improve CAR T cell design and bypass potential challenges faced when generating effective CAR T cells for pediatric AML.

1532 Suspension Like Scalability of AAV9 Production in Adherent Cells

Brian Ladd, Véronique Chotteau
KTH, Stockholm, Sweden

The viral vector based on the non-pathogenic, replication deficient virus, adeno-associated virus (AAV) is a very popular tool due to a favorable safety profile and little immune response. Of the four approved and five pre-registration *in-vivo* viral vector gene therapies, six use rAAV. These upcoming therapies will place a burden on current production methodologies requiring improvements in overall titers and lowering of the cost-of-goods. Production of rAAV vectors in cell aggregates could be a way to both intensify and scale up adherent cultures. Adherent cell culture is challenging to scale up, due to scaling with the surface area rather than the volume like a suspension-based process. Methods do exist to increase this scalability; such as microcarriers or fixed bed systems. These systems are however not without some limitations, namely the maximum cell density that can be achieved and the ease of use of the system. The aim of the work presented here is to circumvent these limitations by using cell aggregates. This novel rAAV allows for higher cell densities to be achieved, not only facilitating the scale up but also the intensification of AAV production. Production of rAAV9-GFP was achieved in HEK293T cell aggregates by means of the transient transfection process. It was demonstrated that this novel rAAV production method can maintain similar cell specific production of adherent cells attached to microcarriers, but in a more scalable and intensified process. Using the HEK aggregate system cell specific productivities greater than 10^4 capsids per cell have been achieved with cell densities exceeding $7 \bullet 10^6$ MVC/mL in a 200 mL bioreactor. In addition to this a simplified perfusion method was developed allowing the HEK293T aggregates to be cultured for an extended period of time, opening the door to continuous processes.

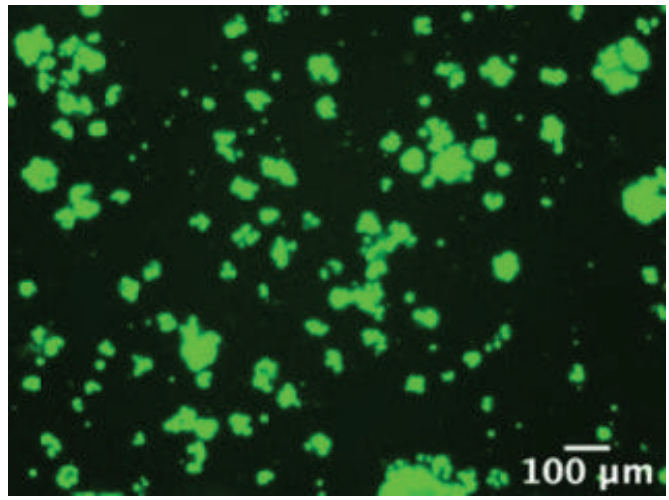

Figure 1: Fluorescent image of HEK293T cell aggregates after triple transfection for rAAV9-GFP production. Ex: 460 nm - 500 nm. Em: 512 nm - 542 nm

1533 Rescue of Hearing Loss in a STRC KO Mouse Using Multiple Dual Vector Gene Therapy Strategies

Nivanthika Wimalasena[1], Tian Yang[1], Tyler M. Gibson[1], Quynh-Anh Fucci[1], Madeline Barnes[1], Luke Shaheen[1], Jahneal Francis[1], Sarah Cancelarich[2], Leah Sabin[2], Meghan Drummond[2], Joseph Burns[1], Lars Becker[1], Ning Pan[1], Ryan McCarthy[1]
[1]Decibel Therapeutics, Boston, MA,[2]Regeneron, Tarrytown, NY

Background Stereocilin (STRC) is a large structural protein expressed in outer hair cells (OHCs) of the cochlea, forming lateral links between adjacent stereocilia as well as attachments between the tallest row of stereocilia and the tectorial membrane. STRC is critical for OHC-mediated cochlear amplification. Human patients with loss-of-function mutations in *STRC*, classified as DFNB16, exhibit moderate hearing loss due to a defect in cochlear amplification. DFNB16 is an autosomal recessive form of hearing loss and is the second most prevalent cause of genetic auditory dysfunction in the US and EU and is a candidate for AAV-based gene replacement. Methods Due to the large size of the STRC gene and the packaging capacity of AAV, delivery of STRC gene replacement therapy to the inner ear can only be accomplished using a dual AAV approach. Using a combination of *in vitro*, *ex vivo*, and *in vivo* assays, we examined the following dual vector strategies to express STRC protein: 1) overlapping (OV), 2) dual hybrid (DH), and 3) intein trans-splicing. HEK293T cells and mouse utricle explants were transduced with dual vector tools and relative protein expression was determined via immunoblot or immunohistochemistry, respectively. For *in* vivo studies, equal titers of dual AAV were combined and delivered locally to the inner ear via the posterior semicircular canal. Immunohistochemistry was performed on cochlea whole mounts to determine levels of transgene expression. Hearing levels of untreated Strc KO mice and those treated with Strc gene therapy were assessed using auditory brainstem response (ABR) and distortion product otoacoustic emissions (DPOAEs). Results

To compare the recombination efficiencies of the three dual vector strategies, we leveraged relatively high-throughput *in vitro* and *ex vivo* assays. HEK293T cells and mouse utricle explants were transduced with equal titers of each dual AAV tool (OV, DH, or intein). We found that STRC protein was produced with each dual vector strategy. Additionally, the STRC transgene was trafficked to the utricle hair cell kinocilia of STRC KO explants treated with the intein dual vector tool, demonstrating the same expression pattern seen in wild-type mice. To determine the impact of dual AAV-Strc in a Strc disease model, we delivered virus to the inner ear of neonatal Strc KO mice. Hearing (ABR and DPOAE) was improved in Strc KO mice treated with either OV or intein Strc gene therapy. Next, we quantified the number of OHCs with Strc transgene expression and found a correlation between OHC transgene expression and improvement in hearing thresholds. Lastly, we demonstrate delivery of dual vectors to the inner ear of adult mice results in efficient recombination and transgene expression in OHCs. Conclusion Our data highlights the utility of the dual vector strategies presented in delivering a large gene, such as STRC, to the inner ear of mice. The implications of these findings are important as we consider the development of gene therapy products to replace "large genes" in the inner ear.

1534 Mantarray 3D Engineered Muscle Tissue Platform Demonstrates Clinically-Relevant Disease Stratification of an *In Vitro* Duchenne Muscular Dystrophy Model

Shawn Luttrell, Daniel Lih, Kevin Gray, Samir Kharoufeh, Christal Worthen, Greg Luerman, Nicholas Geisse

Curi Bio, Seattle, WA

Accurately modeling healthy and disease conditions in vitro is vital for the development of new treatment strategies and therapeutics. For cardiac and skeletal muscle diseases, direct assessment of contractile output is a reliable metric to study overall tissue function, as other 'proxy' measurements are poor predictors of muscle strength. Human 3D engineered muscle tissues (EMTs) from induced pluripotent stem cell and primary cell sources hold great potential for modeling contractile function. However, the bioengineering strategies required to generate these predictive models presents limitations for many investigators. Here, we have developed a platform that utilizes 3D EMTs in conjunction with a label-free magnetic sensing array (Mantarray). The platform enables facile and reproducible fabrication of 3D EMTs using virtually any cell source and is coupled with individual, well-based control of stimulation and highly parallel direct measurement of contractility. This approach enables clinically relevant functional measurements of muscle, stratification of healthy and diseased muscle phenotypes, and facilitates compound safety and efficacy screening. We present a 3D model of Duchenne muscular dystrophy that utilizes skeletal muscle EMTs formed from an isogenic pair of healthy and diseased cells. These tissues achieve robust twitch and tetanic responses upon stimulation. The model presents functional deficits across numerous metrics of contractility, including force and fatigability. EMTs remain functional for weeks to months in culture and provide a large experimental window to not only study therapeutic effect, but also disease phenotypes that may present at later stages of development and maturity. We have also established a method to suspend these EMTs in a biocompatible gel that permits transfer of tissues between labs. Tissues remain viable and fully functional upon gel dissolution for direct interrogation with therapeutic compounds, eliminating the need to fabricate EMTs in-house. These data demonstrate a first-and-only commercial platform integrating individual, well-based control of electrical stimulation across a 24-well plate to pace 3D tissues, modeling exercise regimens or damage protocols in muscle constructs. Stimulation is coupled with automated assessment of 3D muscle contraction, providing an inclusive, high-throughput platform for disease modeling and therapeutic discovery.

1535 Designing Cell-State-Specific Synthetic Promoters as Smart Sensors to Control Macrophage Polarization

Frances D. Liu[1], Michelle Hung[1], Assen Roguev[1], Yin Yin Chong[1], Eniola Catton[1], Jessica Haverkamp[2], Panos Douvaras[2], Alex Danza[1], Monika Avina[1], Mark Tomishima[2], Russell Gordley[1], Gary K. Lee[1], Timothy Lu[1]

[1]Senti Biosciences, South San Francisco, CA,[2]BlueRock Therapeutics, New York, NY

Background: Macrophages are a plastic cell type that can be polarized to a pro-inflammatory (M1) or an anti-inflammatory (M2) state. Macrophages localize to sites of inflammation, making them an attractive cell therapy or drug delivery vehicle, but macrophage plasticity can hamper the desired therapeutic effects. For example, M2 macrophages play a key role in promoting tissue repair in pathological conditions such as wound healing, atherosclerosis, neurodegeneration, liver fibrosis, and autoimmune disease. However, the inflammatory microenvironment converts therapeutic M2 macrophages to pathologic M1 macrophages. Here, we leverage macrophage ability to sense M1 cues to discover and engineer M1 polarization-state specific promoters that can be used to redirect endogenous signaling pathways. These promoters enable controlled immune payload expression in locoregional areas of pathological inflammation. When used to drive M2 cues, these M1 promoters enable autonomous control over macrophage polarization state to switch M1 macrophages towards an M2-like state. **Methods:** We implemented 2 strategies to discover M1 state selective promoters:1) We identified >60 genes upregulated in M1 macrophages relative to M0 and M2 macrophages across multiple transcriptomic datasets. The DNA upstream of those genes were used as native promoter sequences driving fluorescent reporters. Promoter activity was assessed by fluorescence in M1, M0, and M2 states compared to a constitutive control promoter (EFS). 2) We bioinformatically designed a synthetic promoter library containing combinatorial concatenations of M1-associated transcription factor binding motifs and enhancer sequences. Employing a massively parallel reporter assay (MPRA), we assessed promoter activity for M1, M0, and M2 macrophages across 3 biological replicates. **Results:** From approach 1, we discovered 3 promoters that had >10-fold higher activity in the M1 vs. M0 and M2 states with promoter strength at 80-240% of EFS. We optimized the weakest promoter by systematically removing regulatory elements to identify those that actively contribute to promoter activity or actively inhibit it. We then rationally re-engineered that sequence to increase promoter strength

by 3-4-fold (from 80% to 230-320% of EFS) while maintaining the same level of M1-selective activity. From approach 2, we selected >60 synthetic promoter candidates from the library with the highest-fold change in activity in the M1-state relative to the M0 and M2 states from MPRA. When clonally validated, nearly all synthetic promoters had selective activity in the M1-state, and ~14% had >10-fold selective activity in the M1 vs. M0 and M2 states. We demonstrated the utility of these cell-state-specific promoters to sense inflammatory cues and to resolve inflammation. Specifically, we used an M1 selective promoter to express an M2-associated cytokine payload, IL-10. When the engineered macrophages were exposed to M1 polarization cues, the synthetic promoter switched on to achieve state-specific expression of IL-10, which successfully suppressed M1 biomarker expression and switched the macrophages towards an M2-like phenotype. **Conclusion:** We developed and validated systematic and massively parallel strategies for discovering and engineering strong, macrophage-polarization state-selective promoters. Moreover, we demonstrated that the combination of these state-selective promoters with a cytokine payload can impose self-regulation of macrophage polarization. This work indicates that potent and state-selective promoters can be used to control cell-state and create complex "sense-and-respond" gene circuits that enable finely controlled macrophage-based cell therapies.

1536 CRISPR/Cas9 Gene Editing Increases the Risk of Tumorigenesis in Hereditary Tyrosinemia Type I

Tong Chen[1], Mercedes Barzi[1], Nika Furey[1], Hyunjae R. Kim[2], Francis Pankowicz[3], Xavier Legras[1], Sara H. Elsea[2], Ayrea M.S Hurley[2], David A. Wheeler[2], Malgorzata Borowiak[2], Beatrice Bissig-Choisat[1], Pavel Sumazin[2], Karl-Dimiter Bissig[1]

[1]Duke University, Durham, NC,[2]Baylor College of Medicine, Houston, TX,[3]Spark Therapeutics, Philadelphia, PA

The therapeutic potential of CRISPR gene editing has been demonstrated in various animal models, however, little is known about its long-term consequences *in vivo*. Here, we evaluate the impact of CRISPR gene therapy in an animal model of hereditary tyrosinemia type 1 (HT-1) after twelve months. CRISPR deletion of the gene hydroxyphenylpyruvate dioxygenase (*Hpd*) and pharmacological inhibition of enzyme HPD (standard of care) both demonstrate efficient metabolic correction and rescue of lethality. Surprisingly, we detect a markedly increased incidence of hepatocellular cancer in the genome-edited group, with deletions and vector integrations into the host genome. Although HT-1 is characterized by inherent cancer susceptibility, our work describes a severe adverse event associated with CRISPR gene therapy, exposing potential limitations of gene editing approaches in cancer-prone disorders.

1537 Streamlining AAV Characterization: A Capillary Electrophoresis Platform for Capsid Content Analysis

Will McElroy, Chris Heger

Applications Science, Bio-Techne, San Jose, CA

Adeno-associated viruses (AAVs) have gained popularity in recent years for their use in therapeutic gene delivery. These complex biotherapeutics consist of both protein and genetic components, including single-stranded DNA (ssDNA) within a protein capsid. We recently published a study that analyzed the charge heterogeneity of denatured AAV capsid proteins using native fluorescence imaged cIEF, which can be used to assess identity and stability. In this study, we used the Maurice capillary electrophoresis instrument to determine if AAVs contain DNA. Our method involves analyzing two commercially available series of AAVs with varying amounts of DNA and using the results to estimate the DNA content of unknown samples.

1538 Maximizing Cationic Lipid-Based Transfection Efficiency and an Analysis of mRNA Expression in Human Prostate Cancer

Jared Anderson

Chemical and Biochemical Engineering, Villanova University, Villanova, PA

Gene therapy involves the treatment of disease by delivering new genes into a patient's cells. The mechanism of this transfer, or the vector, strongly influences the host cell response to foreign DNA. Viral gene therapy vectors are naturally equipped to deliver transgenes with precise targeting and controlled expression, however the potential risk of inducing an inflammatory immune response drives researchers to explore nonviral vectors for gene delivery. Although safer, these nonviral transfection methods are generally less efficient compared to established viral transduction. The purpose of this research is to maximize transfection efficiency of a cationic lipid-based nonviral vector (Lipofectamine LTX supplied by ThermoFisher Scientific) in human prostate cancer cells and to evaluate the host cell response to the pEF-GFP plasmid (Addgene #11154) by altering the amount of plasmid in the lipoplex formulation. The transfection efficiency was measured as the percentage of the population displaying GFP fluorescence via flow cytometry. Specifically, 0.1-2 μg of pDNA was mixed with 2.75 μL of Lipofectamine LTX and then added to wells of 100,000 PC-3 cells in a 24-well plate. The amount of plasmid DNA in the preparation had a significant effect on the transfection efficiency in PC-3 cells (see Figure 1). Surprisingly, the transfection efficiencies improved significantly at lower pDNA levels than the recommended 0.5 μg/well. We attempted to explain this phenomenon by comparing host cell gene expression patterns between PC-3 samples transfected with 0.1 μg and 1.0 μg of pDNA per well (at 48 hours post transfection). The results showed significant upregulation of a few cytokines in the samples transfected with the higher amount of pDNA (1 μg/well) compared to the low (0.1 μg/well) and non-transfected groups (see Figure 2). Two of these cytokines, IL-6 and IFNL1, are associated with activation of the JAK/STAT signaling cascade, subsequently inducing expression of several antiviral genes (AVGs) and inflammatory cytokines. The ZAP and ISG20 AVGs induce mRNA degradation and translational silencing of foreign nucleic acids. An excessive concentration of pDNA may have elicited this immune response, thereby encouraging transgene silencing

and degeneration. Altogether, these data show that inflammation can be minimized in transfected cells by minimizing the amount of pDNA delivered to the cells (while also maximizing transfection efficiency).

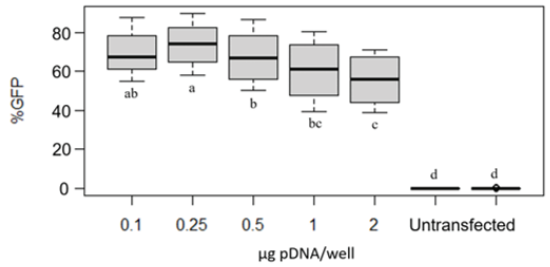

Figure 1. Box and Whisker plot for transfection efficiency in PC-3 cells with Lipofectamine over a range of pEF-GFP concentrations (0.1-2 µg/well of PC-3 cells; Untransfected groups represent negative controls that were not transfected). Cells were seeded at 50,000/well in a 24-well plate then transfected after 24 hours. Measurements of transfection efficiency (%GFP+ cells) were taken at 48 hours post-transfection. Letters (a-d) indicate groups of samples with statistically significant differences in transfection efficiency that were determined using a Friedman's test ($p < 0.05$). Error bars, or the "whiskers", extend to the maximum and minimum data points outside the upper and lower quartile range.

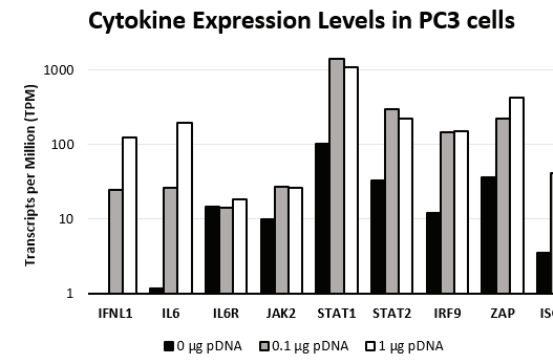

Figure 2. Bar chart showing mRNA expression levels (TPM) of significantly upregulated cytokines in PC-3 cells and the JAK/STAT pathway transfected with varying levels of pDNA (0, 0.1, and 1 µg per well). Statistical significance was determined by a Padj < 0.05 using DESeq2.

1539 CRISPNA, a New Tool for Genome Editing and Diagnosis

Araceli Aguilar-González[1,2], Noelia Maldonado-Pérez[1], Francisco Javier Molina-Estévez[1], Iris Ramos-Hernández[1], Pilar Puig-Serra[3], Raul Torres[3], Sandra Rodríguez-Perales[3], Rosario María Sánchez-Martín[1,2], Juan-José Díaz-Mochón[1,2], Francisco Martín[1,4]

[1]GENYO, Granada, Spain,[2]Department of Medicinal & Organic Chemistry. Faculty of Pharmacy, University of Granada, Granada, Spain,[3]Spanish National Cancer Research Centre (CNIO), Madrid, Spain,[4]Departament of Biochemistry and Molecular Biology 3 and Inmunology. Faculty of Medicine, Universidad de Granada, Granada, Spain

CRISPR/Cas systems are powerful technologies that are changing the way scientists tackle unsolved problems in basic biology, therapy and diagnosis. The different CRISPR/Cas systems require RNA molecules (crRNAs or sgRNAs) to direct the different Cas proteins to their DNA or RNA targets. In spite of their potency and specificity, the RNA molecules could be unstable in some conditions and can allow several mismatches when binding to their target. Peptide Nucleic Acids (PNAs) artificially synthetic oligonucleotides that display higher affinity and specificity to complementary DNA and RNA compared to normal oligonucleotides. Therefore, PNA-RNA and PNA-DNA bindings are more stable and specific than RNA or DNA. In addition, their uncharged backbone makes PNAs extremely stable in biological fluids because of their resistance to proteases and nucleases. In this work, we propose the generation of a new tool called CRISPNA which combines the versatility of CRISPR-associated enzymes (Cas) with the robustness, stability, and specificity of PNAs. Our results show that PNAs can redirect different Cas proteins (Cas9 and Cas13) to their respective targets. Further analysis showed that the enzymatic activity of CRISPNA/Cas9 was abrogated while CRISPNA/Cas13 system was fully functional. We showed that the CRISPNA/Cas13 complex had sequence-specific cis- and trans-RNAase activity. Compared to CRISPR/Cas13, the CRISPNA/Cas13 complex had lower RNAase activity (near zero) in the absence of RNA target. This low background activity allows the CRISPNA/Cas13 system to outperform CRISPR/Cas13 in terms of specificity at large (3 hours) incubation times. This new development allows to open new possibilities for different applications.

1540 A Self-Amplifying RNA Vector Expressing Nanobodies Against Immune Checkpoints Induces Potent Antitumor Responses

Noelia Silva Pilipich[1], Ester Blanco[2], Teresa Lozano[1], Eva Martisova[1], Ana Igea[1], Guillermo Herrador Cañete[1], María Cristina Ballesteros Briones[1], Marta Gorraiz[1], Patricia Sarrión[1], Gualberto González Sapienza[3], Juan J Lasarte[1], Lucia Vanrell[4], Cristian Smerdou[1]

[1]Cima Universidad de Navarra, IdISNA and CCUN, Pamplona, Spain,[2]Oncoimmunology Research Unit, Navarrabiomed and IdISNA, Pamplona, Spain,[3]Cátedra de Inmunología, Facultad de Química, UDELAR, Montevideo, Uruguay,[4]Facultad de Ingeniería-Universidad ORT and Nanogrow Biotech, Montevideo, Uruguay

Immune checkpoint blockade using monoclonal antibodies (mAbs) has revolutionized the way cancer is treated. However, a large fraction of patients does not benefit from these treatments, with responses being mainly limited to immunogenic tumors. In addition, systemic administration of high doses of mAbs can generate toxicity. In the present work, we aimed to improve this therapy by optimizing both the therapeutic antibodies and their route of delivery. We generated novel nanobodies against PD-1 and PD-L1 capable of inhibiting both human and mouse interactions. Nanobodies have several advantages over conventional antibodies, such as a small size, monomeric nature, high tissue penetration and high stability. By fusing nanobodies to the fragment crystallizable (Fc) domain of mouse IgG, dimeric molecules were obtained. These dimers showed a significant reduction of IC50 for PD-1/PD-L1 interactions compared to the monomeric versions, reaching a similar or higher inhibition than commercial antibodies, including nivolumab and atezolizumab. Local administration of therapeutic antibodies could help decrease adverse systemic effects while increasing their concentration within the tumor, potentially

enhancing their therapeutic effect. To deliver nanobodies locally in tumors, we used a self-amplifying RNA (saRNA) vector based on Semliki Forest Virus (SFV). This system provides a high and transient expression of the gene of interest, inducing immunogenic cell death and type I interferon responses, which could function synergistically with immune checkpoint blockade. SFV viral particles expressing dimeric nanobodies showed a potent antitumor activity in a colorectal cancer model (MC38), resulting in >50% complete regressions and outperforming SFV vectors expressing conventional mAbs against PD-1 and PD-L1. The therapeutic potential was also validated in melanoma models (B16F10 and B16OVA). Although short-term expression of nanobodies was observed due to the cytopathic nature of the saRNA vector, it was sufficient to induce a potent inflammatory response in tumors, as observed by RNAseq and flow-cytometry analysis. Notably, increased infiltration of NK and $CD8^+$ T cells were observed in tumors treated with SFV vectors encoding nanobodies. Interestingly, the SFV system can also be employed as a non-viral vector, preserving its potential to induce cell death and inflammation due to the RNA self-amplification. Since non-viral approaches are usually easier to translate to the clinic, we tested this possibility by using a DNA plasmid able to transcribe the SFV replicon expressing the anti-PD-1 dimeric nanobody in vivo. This plasmid was administered in tumors in combination with local electroporation, yielding a strong antitumor effect in the MC38 tumor model. No indication of toxicity was observed using viral or non-viral SFV vectors encoding dimeric nanobodies. These SFV vectors constitute attractive tools that could improve the response rate to PD-1/PD-L1 inhibitors, avoiding subjecting the patients to high doses of antibodies that can have adverse effects in healthy organs. Finally, the cross-reactivity of the nanobodies described here towards human molecules is an unusual but advantageous characteristic that could pave the way for the future clinical evaluation of these agents.

1541 Therapeutic Efficacy of the Combination of Long-Term Penicillamine Treatment with a Single Administration of VTX-801 in Wilson's Disease Mice

Oihana Murillo[1], Daniel Moreno-Luqui[1], Cristina Gazquez[1], Miren Barberia[1], Blanche Tamarit[2], Anne M. Douar[2], Bernard Benichou[2], Jean-Philippe Combal[2], Ruben Hernandez-Alcoceba[3], Veronica Ferrer[2], Gloria Gonzalez-Aseguinolaza[4]

[1]Gene therapy, Cima Universidad de Navarra, Pamplona, Spain,[2]Vivet Therapeutics, Paris, France,[3]FIMA Center for Applied Medical Research, Pamplona, Spain,[4]Gene therapy, Vivet Therapeutics, Pamplona, Spain

Wilson's disease (WD) is a rare disorder of copper metabolism inherited in an autosomal recessive manner. It is due to missense mutations in *ATP7B*, a copper-transporting P-type ATPase, that lead to hepatic, neurologic, or psychiatric symptoms. Left untreated, the condition progresses to severely debilitating complications and death. Current medical management relies on life-long oral treatment with copper chelators such as D-penicillamine (DPA) or zinc salts. VTX-801 is a recombinant adeno-associated vector (rAAV) carrying a shortened version of the human ATP7B gene. VTX-801 has demonstrated to provide long-term correction of copper metabolism and ceruloplasmin levels, preservation of liver integrity and function when administered at early stage of the disease in WD mice. Based on these results, GATEWAY, a phase I/II clinical trial was initiated to evaluate VTX-801 in adult patients with WD. We then evaluated the therapeutic effect of a single administration of VTX-801 in 20-week-old WD mice treated with DPA from 4 weeks of age. Efficacy was assessed through analysis of copper content in urine, blood and tissues, transaminases, hematology and histological analysis, including markers of inflammation and fibrosis at sacrifice, 24 weeks after VTX-801 injection. All treatments (DPA only, VTX-801 only and DPA+VTX-801) reduced the levels of hepatic copper in WD mice. Nonetheless, only the groups of mice treated with VTX-801 displayed a significantly lower concentration of copper in liver (compared to untreated WD mice), with lowest levels in mice receiving the combination. The percentage of exchangeable to total serum copper (REC), that appreciates the toxic fraction of copper in blood, was high in DPA-treated mice but was normalized by VTX-801 treatment alone or in combination with DPA. Moreover, ceruloplasmin activity in circulation was restored only in VTX-801 treated animals. These results emphasize the strong de-coppering effect of the combination therapy with long-term DPA followed by a single administration of VTX-801. Importantly, no copper deficiency was observed in those mice. Compared to the natural progression of liver pathology observed in WD mice, animals treated with VTX-801 showed a significant decrease in inflammatory cell focus/foci, diffuse hepatocyte hypertrophy and fibrosis, but also displayed increased steatosis. DPA-treated animals showed a normal liver parenchyma, when administered alone or in combination with VTX-801. When combined with DPA treatment, VTX-801 reduced severity score for all the histological parameters tested. Altogether these results indicate that treatment with a copper chelator contributes to stabilization of liver disease progression in WD mice. DPA treatment significantly improved the therapeutic efficacy of VTX-801 when administered at 20 weeks of age resulting in full restoration of copper metabolism in the absence of adverse events.

1542 Mechanistic Model for AAVs on Anion Exchange Chromatography

Ohnmar Khanal, Vijesh Kumar, Mi Jin

Spark Therapeutics, Philadelphia, PA

AAVs are widely used delivery vehicles for gene therapy. However, the production cost of AAV-mediated gene therapy is exorbitant, necessitating targeted process development efforts. The purification of AAV capsids is particularly challenging, given capsids without transgene or an incomplete copy of the transgene can make up 70-90% of the total output from the bioreactor. The current framework for purification process development remains inefficient. Computational strategies such as mechanistic chromatography modeling based on the well-established detailed fundamental understanding of chromatography can expedite late-phase process development for empty and full capsid separation. Although modeling the transport of a large molecule, such as rAAV, through chromatography resin is very challenging, it was overcome using an advanced general rate model, which included variable surface diffusion. We demonstrate the utility of such a mechanistic model for separating a recombinant AAV capsid on Poros XQ resin. We show that the model can determine capacity, preferred loading range, conversion from gradient to step elution,

and process robustness to variation in loading material and column dimensions. Furthermore, the model's utility was demonstrated for scale-up/scale-down considerations.

1543 SKG0201: A Next Generation Gene Therapy for Spinal Muscular Atrophy with Better Efficacy and Safety Profile

Carol Huang, Yanqun Shu, Shihua Cao, Ruojie Wang, Yu Wu, Peilu Li, Yao Qiu, Xia Liu, Yanjun Shen, Hui Liu, Xiaorui Bian, Liuye Yao, Ruoyan Hu, Yuwen Du, Li Wang, Hao Luo, Jay Hou

Skyline Therapeutics, Cambridge, MA

Spinal Muscular Atrophy (SMA) is caused by the homozygous deletion or mutation of the survival motor neuron 1 (*SMN1*) gene, resulting in reduced expression of SMN protein, which leads to degeneration of α motor neurons in the spinal cord and muscle atrophy. Although gene therapy product, Zolgensma, was developed and marketed, it has been reported that the drug has tolerability issues, such as significant liver toxicity, and some blood-related toxicity due to the high doses of the vector. Hence, a new AAV gene therapy for SMA with a improved safety profile and better efficacy is in desperate need. We have developed a novel AAV-mediated gene replacement product (SKG0201) which innovatively comprises an optimized human *SMN1* cDNA under the control of a unique human promoter. Every element in the vector genome has been meticulously optimized to fully attain restoration of SMN to achieve maximal therapeutic effect in the CNS while maintaining appropriate expression in peripheral tissues. Our preclinical data demonstrated that a single intravenous administration of SKG0201 resulted in a rapid and long-lasting correction of functional SMN levels, which led to a significant improvement in the body weight gain and extension in the lifespan of SMNΔ7 mice at low doses. Furthermore, SKG0201 displayed a much stronger potency with no liver toxicity compared to the reference vector (scAAV9-CMVen/CB-hSMN1), suggesting that a lower dose could be used in the clinical setting, further enhancing the safety profile of the vector. Moreover, SKG0201-treated SMNΔ7 mice exhibited a lasting efficacy in improving deficits of motor functions, preventing NMJ breakdown, and increasing the axon conductivity in six-month durability studies. The vector in the animals also manifested a strong anti-inflammatory and neuroprotective effect in the CNS, and anti-fibrosis and protective roles in the heart and liver. Additionally, our pilot 13-week study in neonatal cynomolgus monkeys (NHP) showed that a single intravenous administration of SKG0201 mediated a high expression level of hSMN in the CNS, suggesting that the expression of the transgenes was robust and long-term. Importantly, the vector was safe and well tolerated in the study. Currently, a 26-week toxicology and biodistribution study in NHP is on-going. In summary, our results strongly suggest that SKG0201, with a potentially superior efficacy and safety profile, represents a new generation of AAV gene therapy for SMA patients.

1544 Real World Evidence of Chimeric T Cell Therapy Safety: Analysis of the FDA Adverse Event Reporting System (FAERS) Database

Moataz Ellithi[1], Magdi Elsallab[2], Matthew Lunning[1], Christopher D'Angelo[1]

[1]Hematology and Medical Oncology, University of Nebraska Medical Center, Omaha, NE,[2]Harvard-MIT Center for Regulatory Science, Boston, MA

Introduction: With the growing population of patients receiving novel chimeric antigen T cell (CAR-T) therapies, the prevention, early identification, and management of the associated toxicities and long-term complications becomes critical. To identify patterns and trends in the adverse events (AEs) associated with CAR-T cells, we analyzed the adverse events reported in the Food and Drug Administration Adverse Event Reporting System (FAERS). The FAERS database contains voluntarily submitted reports of drug adverse events. Methods: FAERS quarterly reports files were downloaded in ASCII format. We limited the data to reports submitted from October 2017 (the date of FDA approval for the first CART product) to the latest FAERS submission (September 2022). Reports were merged and filtered by the drug involved, using string searching and manual curation. Reports involving axicabtagene ciloleucel, brexucabtagene autoleucel, lisocabtagene maraleucel, tisagenlecleucel, ciltacabtagene, or idecabtagene vicleucel were all included. Data included patient demographics, adverse event information, and outcomes. Data were processed to eliminate duplicated entries. Descriptive statistics were used to summarize the data. Adverse events were analyzed and compared between products and to the other approved treatments for similar indications. Analysis was performed using RStudio, version 4.2.2. Results: We retrieved a total of 10,388 reports on the beforementioned products. The majority of events occurred in North America (71%), followed by Europe (19%), and Asia (4%). The majority of reporters were physicians (45%). Death occurred in 2,383 (23%) reports and was most frequently reported in the tisagenlecleucel list (28%). Tisagenlecleucel had the highest median adverse events per report (4 [IQR 2-9]), while idecabtagene had the lowest (1 [IQR 1-2]). Idacabtagene reactions resulted in the lowest number of deaths, compared to the other groups (14.7%). Cytokine release syndrome (CRS) was the most frequently reported AE (50% of reports). CRS was reported the most in Idecabtagene (60%), brexucabtagene (59%), and axicabtagene (55%), while was reported less in ciltacabtagene (17%) and lisocabtagene (28%). Fifty-one percent of mortality reports had CRS listed. Immune-effector cell associated neurotoxicity (ICANS) was the second most commonly reported AE and was present in 38% of reports. ICANS occurred in 58% of brexucabtagene and 51% of axicabtagene reports, while was present in only 10% of ciltacabtagene reports. We noted reports on other malignancies or second primary cancers, which were listed in up to 7.6% of ciltacabtagene reports, 5.8% of lisocabtagene, 4.2% of axicabtagene, 1.9% of tisagenlecleucel reports, and in <1% of idecabtagene reports. Myelodysplastic syndromes and acute myeloid leukemias were the most frequently reported, followed by skin cancers. Study limitations: The study is limited to the data available in FAERS, which is subject to reporting bias and may not represent the entire population of patients who have received CAR-T products. The causality of the reported adverse events cannot be determined solely from the FAERS data. Conclusion: Our study provides further

post-marketing information on the safety profile of CAR-T products, which will help healthcare policymakers, healthcare professionals, and patients make informed decisions about the use of these products.

1545 Translational Programs in Gene Therapy and Somatic Cell Genome Editing: Nonhuman Primate Research Opportunities

Alice F. Tarantal[1], Michele Martinez[1], Lionel Sanz[1], David J. Segal[2], Dennis J. Hartigan-O'Connor[3]

[1]Pediatrics, Cell Biology and Human Anatomy, and California National Primate Research Center, University of California, Davis, Davis, CA,[2]Biochemistry and Molecular Medicine, and Genome Center, University of California, Davis, Davis, CA,[3]Medical Microbiology and Immunology, and California National Primate Research Center, University of California, Davis, Davis, CA

Clinical translation of emerging gene therapy and somatic cell genome editing strategies for the treatment of a range of human diseases requires access to nonhuman primate models. Nonhuman primates represent a critical bridge for translational applications because they can provide a path to understand human biological functions, study complex human diseases, and address the safety of new diagnostics and therapies proposed for human use across the life span. Of primary concern is ensuring safe and efficient editing, which represents the two most fundamental barriers to human clinical use. The Nonhuman Primate Testing Center for Evaluation of Somatic Cell Genome Editing Tools was established in 2019 to develop safe and efficient genome editing methods to treat patients with common or rare diseases. The Testing Center supports a range of NIH-funded projects targeting a variety of organ systems (e.g., brain/CNS, heart, skeletal muscle, lung, liver, kidney, hematopoietic system) through an efficient collaborative process, and is a Large Animal Testing Center in the NIH Somatic Cell Genome Editing (SCGE) Consortium. The SCGE Consortium includes 72 investigators, 45 projects, and 38 institutions across the U.S. focused on developing targeted systems for the delivery of new editors and improved human genome editing tools, and exploring new methods to assess unintended biological effects. A significant concern for the clinical use of gene editors is the potential for immune responses and pre-existing immunity. The Testing Center has a range of capabilities including total-body positron emission tomography (PET) imaging to identify edited cells and assess inflammation and T-cell trafficking. Detection of T-cell reactivity in blood may not accurately reflect local immunologic events at the target site that can reduce efficacy or result in toxicity. In the context of future human gene-editing trials, it will be important to understand how persistent gene expression leads to immune responses and the consequences of these responses for transduced/edited cells. The Testing Center collaborates with members of the SCGE Consortium through their NIH-funded grants and Collaborative Opportunity Fund projects to address these and related questions in nonhuman primate models from early prenatal stages to infants, juveniles, and adults. The Nonhuman Primate Testing Center for Evaluation of Somatic Cell Genome Editing Tools ensures contributions will have a sustained, powerful impact on new treatments for patients across all age groups, including the youngest patients in need.

1546 AAV Selection in the Kidney Reveals a Subset of Distal Tubule Cells at the Juxtaglomerular Apparatus That Are Susceptible to Transduction

Shun Lu, Guochao Wu, Shuya Liu

University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Monogenetic kidney diseases account for around 50% of nondiabetic chronic kidney diseases in pediatric cohorts and 30% in adult cohorts. To date, more than 60 genetic diseases are known to directly or indirectly affect kidneys. Adeno-associated virus (AAV) vectors have shown great potential in gene therapy. However, kidney is considered as a difficult organ for targeting due to its complex structure and function for filtration. Here, we applied a novel approach to discover a kidney-specific AAV vector. In this approach, we screened a new random AAV9 display peptide library in mice using a protocol developed for kidneys. We monitored the selection kinetics using an NGS-based scoring system and increased the selection pressure by separating renal compartments accordingly. By integrating the experimental and bioinformatics workflow we discovered a new AAV9 vector termed AAV9-JGA that specifically targeted in a subset of the thick ascending limb (TAL) characterized as SLC12A1/CLDN16-positive cells at juxtaglomerular apparatus (JGA) after systemic administration. Intriguingly, we demonstrated that this subset of TAL at JGA is generally susceptible to AAV transduction and revealed a nature transduction route of AAV in the kidney from the bloodstream. We suggest that the targeting specificity of AAV9-JGA is due to the anatomical features of JGA and the different characteristics of TAL cell subtypes in the kidney.In conclusion, we developed a comprehensive strategy and workflow to screen AAV library in vivo and discovered a new AAV vector termed AAV9-JGA which targets a subset of TAL at JGA. We revealed a common transduction route of AAV in the kidney after systemic administration. AAV9-JGA with the ability and potential to target and modulate JGA provides new possibilities for basic research and kidney disease-specific therapy.

1547 Autologous *Ex-Vivo* Lentiviral Gene Therapy for Pediatric Patients with Severe Leukocyte Adhesion Deficiency-I (LAD-I): Interim Results from an Ongoing Phase 1/2 Study

Donald B. Kohn[1], Julián Sevilla[2], Gayatri Rao[3], Maria Chitty Lopez[3], Elena Almarza[3], Dayna Terrazas[1], Josune Zubicaray[2], Marta González-Vicent[2], Kritika Chetty[4], Gráinne O'Toole[4], Jinhua Xu-Bayford[4], Eileen Nicoletti[3], Augustine Fernandez[1], Caroline Y. Kuo[1], Satiro N. De Oliveira[1], Theodore B. Moore[1], Grace Choi[3], Miriam Zeini[3], Cristina Mesa-Núñez[3], Adrian J. Thrasher[4], Juan A. Bueren[5], Jonathan Schwartz[3], Claire Booth[4]

[1]University of California, Los Angeles, Los Angeles, CA,[2]HIUNJ/CIBERER, Madrid, Spain,[3]Rocket Pharmaceuticals, Inc., Cranbury, NJ,[4]UCL Great Ormond Street Institute of Child Health, London, United Kingdom,[5]CIEMAT/CIBERER/IIS-FJD, Madrid, Spain

Background: Severe leukocyte adhesion deficiency-I (LAD-I) is an autosomal recessive inborn error of immunity due to mutations in the

ITGB2 gene that encodes the common subunit of β2-integrins (CD18), essential for neutrophil adhesion to the inflamed endothelium and transmigration into tissues. Severe LAD-I, defined as <2% of normal CD18 polymorphonucleocyte [PMN] expression, is characterized by frequent and often refractory bacterial and fungal infections, impaired wound healing, and significant pediatric mortality in the absence of allogeneic hematopoietic stem cell transplant (alloHSCT). AlloHSCT is potentially curative but limited by donor availability, graft-versus-host disease, and graft failure. The gene therapy RP-L201-0318 (NCT03812263) employs autologous CD34+ cells transduced with a lentiviral vector carrying *ITGB2* to restore CD18 expression. **Methods:** Patients ≥3 months old with severe LAD-I were enrolled. Hematopoietic stem cells (HSCs) were collected via apheresis after mobilization with granulocyte-colony stimulating factor and plerixafor and transduced *ex-vivo* with Chim-CD18-WPRE-LV. Myeloablative therapeutic drug monitoring (TDM) busulfan conditioning preceded RP-L201 infusion. Patients were followed for safety and efficacy measures, including survival to age two and ≥1-year post-infusion, peripheral blood (PB) PMN CD18 expression, PB vector copy number (VCN), neutrophilia improvement, decrease in infections/hospitalizations, and resolution of skin/periodontal abnormalities. **Results:** Nine patients (age 5 months to 9 years) received RP-L201 with follow-up of 12 to 36 months. RP-L201 cell doses ranged from $2.8x10^6$ to $10x10^6$ CD34+ cells/kg with a drug product VCN of 1.8 to 3.8. All nine patients demonstrated PMN CD18 restoration (median expression of 49.7%) with sustained, stable genetic markings (median PB mononuclear cell VCN of 1.72). The overall survival (OS) rate per Kaplan-Meier estimate is 100%, with all patients alive 1 year after RP-L201 infusion (and at age 2y for those enrolled at age ≤1y); no patients have had graft failure or required alloHSCT. Pre-treatment leukocytosis improved uniformly. Infection-related hospitalizations, including prolonged hospitalizations (≥7 days) were significantly reduced following therapy. No RP-L201-related serious adverse events (SAEs) were reported. No evidence of replication-competent lentivirus has been observed. Insertion site analyses indicate highly polyclonal integration patterns across the entire cohort. **Conclusion**: RP-L201 has a favorable safety profile and confers durable correction of the severe LAD-I phenotype in all nine pediatric patients treated, as demonstrated by follow-up of ≥ 1 year encompassing all relevant laboratory and clinical parameters.

1548 A Novel Knockout-Independent CRISPR Strategy to Treat LDLR-Mediated Heterozygous Familial Hypercholesterolemia

Marina Cherniavsky Lev, Sigal Cohen, Adi Ulman, Ygal Levy, Asael Herman, Lior Izhar, Rafi Emmanuel, Ira Gotliv

Emendo Biotherapeutics, Rehovot, Israel

Familial hypercholesterolemia (FH) is a prevalent autosomal dominant disorder characterized by lifelong elevation in low-density lipoprotein cholesterol (LDL-C), which results in early-onset atherosclerosis and coronary events. The vast majority of genetically confirmed FH is caused by pathogenic mutations in the LDLR gene, haploinsufficiency of which leads to reduced LDL-C uptake. Currently available lipid lowering therapies often fail to attain desired LDL-C levels and require lifelong treatment. Furthermore, as FH patients often require higher doses of statins or combination therapy, these patients may be more prone to side effects or develop drug intolerance. We present a "one-and-done", direct and long-lasting therapeutic strategy for upregulating LDLR expression by truncating a section of the *LDLR* gene 3'UTR via CRISPR-based gene editing. For this purpose, we utilized OMNI-A2, a novel proprietary nuclease that we discovered, with high activity and specificity and small size, compatible with encapsulation in lipid nanoparticles. We used this approach in the HepG2 human liver cell line and the Hepa1-6 mouse hepatoma cell line, to assess excision efficiency, changes in LDLR levels and LDL-C uptake. Excised cells showed a significant upregulation of *LDLR* mRNA levels and increase in membrane-bound LDLR as compared to non-treated cells. Importantly, we achieved a 3-fold increase in LDL-C uptake, outperforming currently prescribed therapies. Analysis of off-target editing and inversion events demonstrated the genomic safety of this composition. We proceeded to testing our composition in lymphoblastoid cell lines derived from FH patients across a range of mutations. Using Western Blot, we found an increase in the mature glycosylated form of LDLR in all treated samples. Proof of concept experiments are currently underway in mouse models with elevated LDL-C. These findings support our CRISPR-based gene editing strategy of truncating regions likely responsible for rapid LDLR mRNA turnover to enhance its expression and boost LDL-C uptake. This unique approach could prove useful for a variety of hypercholesterolemia-related disorders.

1549 Novel AAV Capsid Identification and Characterization for Neuromuscular and Cardiac Indications

Jennifer C. G. Green, Jessica F. Boehler, Meghan S. Soustek, Jamie L. Marshall, Tiffany Willacy, Prushti Bhavsar, Kristy J. Brown, Sharon McGonigle, Carl Morris

Solid Biosciences, Charlestown, MA

Adeno-associated virus (AAV) mediated gene therapy continues to be a promising therapeutic path for various diseases, including monogenic neuromuscular and cardiac indications such as Duchenne muscular dystrophy (DMD) and Friedreich's ataxia (FA). However, the high systemic doses currently required to achieve widespread therapeutic benefit can pose potential safety risks. These risks could be decreased or eliminated if therapeutic benefit could be achieved using lower doses through a more targeted and efficacious vector. Numerous strategies exist to engineer novel AAV capsids for these types of improvements. We are continuing to employ rational design approaches to identify capsids exhibiting increased transduction of skeletal and cardiac muscles, while also de-targeting peripheral tissues, such as liver. Selection strategies include several *in vitro* and *in vivo* assays to increase potential translation to humans in future clinical trials. As individual candidates are identified, additional characterization around parameters such as neutralizing antibody escape, mechanism of action, and manufacturing will be evaluated more fully and benchmarked against other naturally occurring and engineered capsids. Previously, we have described AAV-SLB101, a novel AAV capsid that Solid is using in its SGT-003 pipeline program for DMD after observing a 2-4x increase in muscle transduction and ~0.5x decrease in liver tropism in comparison to AAV9 in mice (DMD^{mdx} and wild type) and non-human primates. This is one example of advances in AAV capsid engineering

and the possibility to change the course of AAV-based gene therapy for numerous neuromuscular and cardiac diseases, maintaining high transduction of target tissues at potentially lower doses while decreasing likelihood of safety events.

1550 A Phase 1, First in Human (FIH) Study of Autologous Anti-HER2 Chimeric Antigen Receptor Macrophage (CAR-M) in Participants (pt) with HER2 Overexpressing Solid Tumors

Joanne Mortimer[1], Yara Abdou[2], E. Claire Dees[2], Naoto Ueno[3], Melissa Johnson[4], Richard T. Maziarz[5], Jennifer Specht[6], Yuan Yuan[7], Paula Pohlmann[8], Mathew Angelos[9], Saar Gill[10], Amy Ronczka[11], Thomas Condamine[11], Dan Cushing[11], Michael Klichinsky[11], Debora Barton[11], Ramona Swaby[11], Kim ReissBinder[9]

[1]City of Hope, Duarte, CA,[2]University of North Carolina Lineberger Comprehensive Cancer Center, Chapel Hill, NC,[3]University of Hawaii, Honolulu, HI,[4]Sarah Cannon Research Institute, Nashville, TN,[5]Oregon Health & Science University, Portland, OR,[6]Fred Hutchinson Cancer Center, Seattle, WA,[7]Cedars Sinai Samuel Oschin Comprehensive Cancer Institute, Los Angeles, CA,[8]The University of Texas M.D. Anderson Cancer Center, Houston, TX,[9]University of Pennsylvania Abramson Cancer Center, Philadelphia, PA,[10]University of Pennsylvania Abramson Cancer Center,, Philadelphia, PA,[11]Carisma Therapeutics, Philadelphia, PA

Background: Macrophages are abundant in the solid tumor microenvironment (sTME) and can exhibit both pro- and anti-tumor functions. Macrophages can be redirected by CAR expression to phagocytose cancer cells in an antigen-specific manner. CAR-M can reprogram the sTME and present neoantigens to T cells, leading to epitope spreading and anti-tumor immunity. CT-0508 is comprised of autologous monocyte-derived proinflammatory macrophages expressing an anti-HER2 CAR. Pre-clinical studies showed that CT-0508 induced targeted cancer cell phagocytosis while sparing normal cells, decreased tumor burden, prolonged survival, and was safe and effective. Notably, anti-HER2 CAR-M treatment led to activation of the sTME, with infiltration of CD8+ and CD4+ T cells, NK cells, dendritic cells, and increased activated CD8+ tumor infiltrating lymphocytes. In a pre-clinical model of advanced solid tumor resistant to PD1 blockade, mice treated with anti-HER2 CAR-M combined with a PD1 blocking antibody demonstrated improved tumor control, overall survival, and TME activation compared to either treatment alone, indicating synergy and capacity for CAR-M to sensitize solid tumors to checkpoint blockade. **Methods:** This Phase 1, FIH study is evaluating safety, tolerability, cell manufacturing feasibility, trafficking, TME activation, and preliminary evidence of efficacy of investigational product CT-0508 in 18 pt with locally advanced (unresectable) /metastatic solid tumors overexpressing HER2. Pt previously treated with anti-HER2 therapies are eligible. Filgrastim mobilized autologous CD14+ monocytes are collected by apheresis, followed by manufacturing and cryopreservation. Group 1 pt (n = 9; enrollment complete) received fractionated doses over Days 1, 3, and 5. Group 2 pt (n = 9) receive CT-0508 as a single infusion on D1. Additional cohorts include: CT-0508 co-administered with pembrolizumab and CT-0508 monotherapy administered intraperitoneally in pt with peritoneal predominant disease. Correlative assessments include pre- and post-treatment biopsies and blood samples for safety (immunogenicity), trafficking (qPCR, RNA in situ hybridization), CT-0508 persistence in blood and tumor, target antigen engagement, TME modulation (single cell RNA sequencing), immune response (TCR sequencing) and others.

1551 Immunoadsorption Plasmapheresis for the Removal of Plasma Immunoglobulins to Enable Repeat Dose Administration with an AAV5 Gene Therapy Vector

Brian R. Long[1], Benjamin M. Hock[1], Charles A. O'Neill[1], Jeremy Arens[1], Theresa Seitel[1], Lucy Crockett[1], Francis Relouzat[2], Claire-Maelle Fovet[2], Nathalie Dereuddre-Bosquet[2], Pauline Maisonnasse[2], Helene Letscher[2], Roger Le Grand[2], Christian Vettermann[1], Soumi Gupta[1]

[1]BioMarin Pharmaceutical Inc., Novato, CA,[2]Commissariat a l'Energie Atomique et aux Energies Alternatives, IMVA-IDMIT Center DRF/Institut de Biologie Francois Jacob, Fontenay-aux-Roses, France

The investigation of adeno associated virus (AAV) vectored gene therapies has increased exponentially over the past decade for the treatment of monogenic disorders. However, the presence of pre-existing anti-AAV neutralizing antibodies (AAV NAb) may limit the efficacy of gene therapy. Moreover, a first administration of an AAV vector induces high titers of treatment emergent AAV NAb, which may compromise repeat dose administration with the same vector. Depletion of AAV NAb by immunoadsorption plasmapheresis (IAP) is a strategy that could allow successful vector administration in recipients with either pre-existing or treatment-emergent antibodies. The objective of this study was to evaluate the effectiveness of IAP to remove AAV serotype 5 (AAV5) NAb from animals sensitized by an initial gene therapy dose. Five cynomolgus macaques (*Macaca fascicularis*) were included in this study; four were sensitized by administration of an AAV5 capsid encoding for the beta subunit of cyno chorionic gonadotropin (AAV5-βCG) at a dose of 6E13vg/kg, and one control animal was naïve. All were subjected to IAP for a minimum of 1 day of 4 runs (plasma volume exchanges) to a maximum of 3 days of 3 runs. All 5 animals were challenged with the exact same AAV5 capsid encoding a different protein, human factor IX (AAV5-hFIX) at a dose of 6E13 vg/kg, administered within 10 minutes of the last run IAP. Efficacy of the IAP procedure was functionally evaluated by laboratory measures of plasma IgG and AAV5 total binding antibody (AAV5 TAb) titer, hFIX plasma protein concentration, and quantitation of vector genomes and transcripts in liver tissue. Maximal depletion of AAV5 TAb titer (>99%) was achieved in two animals resulting in a nadir titer of 61 and 59. These two animals achieved approximately 25% and 50% of hFIX plasma protein levels, respectively, compared to the naïve animal (0.8 IU/mL), and a proportional percentage of vector genome copies measured in liver tissue compared to the naïve animal (1.6 x 10^7 cp/µg tissue). Following a variable number of IAP sessions (plasma volume exchanges over consecutive days) and administration of the AAV5-hFIX challenge dose, there was significant perturbation of hematological and biochemical blood parameters; however, all parameters returned to baseline levels within hours or days of the procedure. These results demonstrate the viability of IAP as an immune modulation procedure to deplete AAV5 capsid-specific

antibody titers sufficient to allow repeat dose administration. As such, IAP may enable AAV-based vector gene therapy in patients currently excluded from gene therapy clinical trials or commercial product use due to pre-existing antibodies. Furthermore, additional evaluation of the efficacy of this procedure may be worthwhile in subjects with pre-existing antibody titers resulting from natural exposure to AAV infections, which result in lower antibody titers than the treatment-emergent titers observed here.

1552 Extracellular Vesicles as Efficient Delivery Modality for shRNA

Julia Anna Rädler[1], Giulia Corso[1], Antje Maria Zickler[1], Noriyasu Kamei[2], Wenyi Zheng[1], Dhanu Gupta[1], Samir El-Andaloussi[1]

[1]Karolinska Institutet, Stockholm, Sweden,[2]Kobe Gakuin University, Kobe, Japan

Introduction: Owing to their ability to target virtually any RNA within a cell, RNA interference (RNAi)-based drugs offer an immense therapeutic potential. However, the hydrophilic nature and low bioavailability of naked RNAi agents require a delivery strategy. To date, a plethora of different strategies exist, including encapsulation into synthetic lipid nanoparticles. However, their application suffers from toxic side effects of excipients and predominant hepatic accumulation. Here, we propose the use of extracellular vesicles (EVs), which are naturally occurring nanoparticles that benefit from immune tolerance and the ability to cross biological barriers, as RNAi delivery vehicles. By applying state-of-the-art engineering approaches, we produced EVs that harbor therapeutic amounts of short-hairpin RNA (shRNA) for potent delivery to recipient cells. Methods: EV-producing cells were genetically modified to express 1) a shRNA of interest, 2) AGO2 as an RNA binding protein fused to an EV sorting domain (CD63), and 3) a fusogenic viral glycoprotein to ensure potent delivery to the cytosol of recipient cells. EVs were isolated from the conditioned media of producer cells and purified by size exclusion chromatography. Subsequently, their contents and properties were analyzed by quantifying the shRNA copies present in EVs (RT-qPCR) and by assessing their downstream functionality in terms of eliciting silencing on the mRNA (RT-qPCR) and protein (Western blot) level in recipient cells *in vitro*. Results: Here, we show that engineered EVs are potent delivery modalities for shRNA *in vitro*. Applying our approach to load shRNA targeting Gapdh (shGapdh), we detected up to 1 shRNA molecule per 3 EVs. Strikingly, our loading strategy boosted the number of shGapdh molecules per EV by 160-fold in comparison with stochastic loading by overexpression. In an *in vitro* setting, these EVs achieved an IC50 of 0.17 nM and Gapdh silencing efficiencies up to 90% thereby competing with state-of-the-art transfection of plasmid DNA encoding for shGapdh (Lipofectamine 2000). Apart from shGapdh, we obtained similar results for a shRNA targeting GFP thus demonstrating the versatility of our approach. Furthermore, moving towards a therapeutically relevant target, we are currently evaluating engineered EVs for shRNA delivery *in vivo*. Conclusion: Engineered EVs present a viable option for the delivery of RNAi agents, such as shRNA. Importantly, we are confident that the strategy developed here can be repurposed for the delivery of other small RNA therapeutics including siRNAs. Additionally, considering the modifiable nature of EVs, future studies will achieve cell or tissue specific targeting of EV-encapsulated RNAi drugs therefore opening up therapeutic applications beyond the liver.

1553 Use of *In Vivo* Electroporation for Gene Delivery to the Airways

David Delemos[1], David A. Dean[2]

[1]Department of Pharmacology and Physiology/ Department of Pediatrcis, University of Rochester School of Medicine and Dentistry, Rochester, NY,[2]Department of Pharmacology and Physiology/ Department of Pediatrcis, University of Rochester, Rochester, NY

Cystic Fibrosis (CF) is a multisystem monogenetic disease caused by mutation of the cystic fibrosis transmembrane conductance regulator (CFTR). While great progress in treatment has been made in recent years due to the development of novel therapeutics that can post-translationally increase CFTR activity in most patients, almost 10% of patients do not benefit from these drugs due to their specific CFTR mutations (namely Class I nonsense and many Class V splicing mutants). As such, methods to increase CFTR expression and activity are still needed to provide relief for these patients. Gene therapy is seen as a likely answer to this need. A number of different approaches for CF gene therapy have been developed and tested over the years, but none have yet elicited any significant benefit in patients. The search for effective delivery methods continues. Electroporation is a gene delivery technique that uses electrical fields to create transient pores in the cell membrane that allow the entry of normally impermeable macromolecules into the cytoplasm. We have shown that the electric pulses needed for electroporation can be applied across the chest of an anesthetized animal (mouse, rat, rabbit, and pig) following intratracheal delivery of plasmid DNA and lead to effective and safe gene transfer. However, most of our previous studies have focused on delivery to the alveolar epithelium for short-term gene expression to treat acute injuries; we have not evaluated gene transfer to the airways to any significant degree. To observe gene transfer to the airways, we used plasmids that express GFP or GFP-CFTR fusion proteins for short or long periods, based on the promoters driving expression. Robust gene delivery and expression was seen throughout both large and small airways in the mouse following electroporation. While the CMV promoter expressed for up to 7 days, by 14 and 28 days, no expression was detected. By contrast, the human UbC promoter gave robust gene expression at all times. Approximately 80% of epithelial cells in the airways (n>300 airways, >30 mice) showed GFP expression for either promoter and gene product at early times and UbC constructs continued to show the same expression levels at 28 days post-transfer. Co-staining for cell-type specific markers indicated that approximately 1/3 of the productively transfected cells are ciliated and another 1/3 are secretory cells. Continuing analysis will better define the distribution of gene transfer and expression. We also tested whether electroporation could be used for efficient gene delivery to mucus-filled lungs, an unfortunate characteristic of the lungs of patients with CF. When plasmids expressing luciferase were electroporated into CCSP-betaENaC transgenic mice that show reduced airway surface liquid and abundant mucus, no difference in luciferase expression was detected compared to the gene transfer seen in their wild type littermates. Further, the distribution of gene transfer and expression in mutant and wild type mice was the same. Taken together, our results demonstrate

that electroporation can be used safely for gene transfer leading to short or long-term expression in the airway epithelium and suggest that this delivery approach could be viable for the treatment of CF.

1554 Investigating the Mechanism to Develop a Therapeutic Approach to Resetting Lung Molecular Clock During HIV-Mediated COPD

Kingshuk Panda, Srinivasan Chinnapaiyan, Maria Santiago, Md Sohanur Rahman, Hoshang Unwalla

Immunology and Nano-medicine, Florida International University, Miami, FL

People living with HIV (PLWH) are at an increased risk for chronic obstructive pulmonary disease (COPD), asthma, and poor health outcomes. COPD exacerbations increase with disease progression and predominantly occur at night or in the early morning hours, possibly due to circadian dysregulation in mucus physiology and lung inflammation. Circadian rhythms are near 24-hour biological oscillations mediated by changes in the expression of clock genes. Peripheral circadian clocks can rapidly become desynchronized with adverse environmental stimuli. We are investigating lung inflammation as a consequence of HIV-mediated disruption of the lung clock to identify the mechanism involved. Circadian dysregulation will be determined in a lung-specific HIV-tat transgenic mouse model. Our data suggest that HIV dysregulates the microRNAome to suppress circadian genes. The consequence of bronchial epithelial microRNAome dysregulation and its impact on the lung molecular clock will allow us to identify the miRNAs involved as well as the pathophysiology underlying increased lung inflammation in HIV with a long-term goal towards designing therapeutics to reset the circadian clock and decrease lung inflammation in PLWH.

1555 Engineering the Novel Type V-F CRISPR-Cas System as Versatile and Efficient Genome Editing Tools Delivered by a Single AAV

Xiangfeng Kong[1], Hainan Zhang[1], Guoling Li[1], Zikang Wang[1], Xuqiang Kong[1], Lecong Wang[1], Yao Wang[1], Linyu Shi[1], Yingsi Zhou[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: The type V-F CRISPR-Cas12f system is a strong candidate for therapeutic applications due to the compact size of the Cas12f proteins. Recent studies have shown the huge potential of Cas12f for genome editing in eucaryotic cells. Nevertheless, more efficient CRISPR-Cas12f systems with minimal protospacer adjacent motif (PAM) constrains remain to be discovered. Here we developed novel Cas12f1 as a gene-editing tool delivered by a single AAV. **Methods**: We employed a computational pipeline to annotate Cas12f1 orthologs, CRISPR array, tracrRNAs, and PAM preferences by data mining assembled bacterial genomes. An EGFP-activation reporter system was designed and used to screen functional CRISPR-Cas12f1 systems in human cells. Protein engineering combined with sgRNA optimization were used to generate enhanced Cas12f1 variants with high editing efficiency, high fidelity and broad PAMs. By leveraging small molecule-stabilized domain, a tunable Cas12f1 system was developed. Furthermore, catalytically inactive Cas12f1 variants were constructed and applied in epigenetic editing and gene regulation. **Results**: We identified six undocumented Cas12f1 proteins with nuclease activity in mammalian cells from assembled bacterial genomes. Among them, HE1Cas12f1 and HE6Cas12f1 (~420 aa only, Fig. 1a), which respectively target 5' T-rich and 5' C-rich PAMs, showed the highest editing activity. Through protein and sgRNA engineering, we generated enhanced HE1Cas12f1 (enHE1Cas12f1) and enHE6Cas12f1 variants, with 5'-TTN and 5'-CCD (D = not C) PAMs respectively, exhibiting much higher editing efficiency, broader PAMs, and comparably high fidelity, compared with the engineered variant of Un1Cas12f1 (Un1Cas12f1_ge4.1) (Fig. 1b-1d). Furthermore, we generated a small molecule-inducible enHE1Cas12f1 and demonstrated its activity with paired sgRNAs *in vivo* by single adeno-associated virus (AAV) delivery, wherein a large fragment containing the exon51 of *DMD* (~1,700 bp) was deleted and expression of dystrophin protein was sufficiently rescued in DMD mice generated by deleting mouse exon52 and replacing mouse exon51 with human exon51 (Fig. 2a-2b). Finally, dead enHE1Cas12f1-based epigenetic editing and gene activation could also be efficiently achieved in mammalian cells (Fig. 2c). **Conclusions:** Our data suggested that enHE1Cas12f1 and enHE6Cas12f1 are established as compact and versatile gene editing tools for basic research with remarkable promise for therapeutic applications.

1556 Gene Therapy Development Using an Inducible Knockout Mouse Model of NGLY1 Deficiency

Ailing Du, Xuntao Zhou, Lingzhi Ren, Nan Liu, Chen Zhou, Jialing Yang Liang, Guangping Gao#, Dan Wang#

Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA

NGLY1 deficiency is an ultrarare autosomal recessive deglycosylation disorder caused by biallelic mutations in the *NGLY1* gene encoding cytoplasmic peptide:N-glycanase (NGLY1). NGLY1 is ubiquitously expressed and normally functions as a de-N-glycosylating enzyme that, together with the 26S proteasome, degrades misfolded N-glycosylated proteins in the cytoplasm. Patients suffer from multisystemic involvement including developmental delay, motor function impairment, hypotonia and liver dysfunction, and the neurological

manifestations represent the major disease burden. Currently, there is no treatment for this disease. Unlike in humans, NGLY1 deficiency in mice is embryonically lethal, posing a significant challenge to studying the disease mechanisms and testing AAV-based gene therapy *in vivo*. In this study, we obtained an *Ngly1* inducible knock-out (iKO) mouse model and demonstrated the therapeutic efficacy of brain-directed *NGLY1* gene replacement therapy. The iKO mice carry a loxP-flanked *Ngly1* exon and a tamoxifen-inducible, ubiquitously expressed *cre* transgene that enables tamoxifen-dependent *Ngly1* knockout. We first optimized a neonatal tamoxifen treatment regimen to induce *Ngly1* knockout in multiple tissues. Consequently, the tamoxifen-treated iKO mice exhibited impaired motor function, progressive kyphosis, lower body weight, and a reduced life span. We hypothesized that broadly restoring NGLY1 in the brain via systemic AAV-mediated gene delivery can alleviate the disease phenotype. At 7 weeks old, iKO mice were treated with rAAV.PHPeB expressing a codon-optimized human *NGLY1* cDNA via tail vein injection. We found that the rAAV treatment significantly improved motor function as measured by rotarod test and CatWalk gait analysis. Kyphosis was largely corrected as revealed by X-ray radiography. Body weight and survival were also improved. Our data suggests that brain-directed *NGLY1* gene replacement via systemic delivery is a promising therapeutic strategy for NGLY1 deficiency. Although the superior mouse CNS tropism of AAV.PHPeB vector used in this study does not translate to primate, emerging AAV capsids with enhanced human CNS tropism will enable future translational studies. In addition, our study exemplified using an iKO mouse model to overcome embryonic lethality and to test *in vivo* gene therapy. (#Co-corresponding authors)

1557 Intravitreal Delivery of Ixo-vec for Neovascular Age-Related Macular Degeneration Results in Widespread Expression of Aflibercept in Cynomolgus Monkey Eyes as Confirmed Using *In-Situ* Hybridization

Julio Delano Nieves, Gustavo de Alencastro, Kelly Michiko Hanna, Jenny Vo, Stephanie Lussier, Ruslan N. Grishanin, Brigit E. Riley

Adverum Biotechnologies, Redwood City, CA

Neovascular age-related macular degeneration (nAMD) is an advanced form of age-related macular degeneration (AMD) that is responsible for approximately 90% of cases of severe vision loss due to AMD (Shao, 2016). Vascular endothelial growth factor (VEGF) is a key component in the development and progression of nAMD, and current treatment strategies require frequent anti-VEGF bolus injections. Ixo-vec does not replace or modify an abnormal gene, but instead turns cells into a biofactory that continuously delivers anti-VEGF to the retina with a single IVT injection. Utilizing an AAV2.7m8-based vector optimized for broad transduction of the retina and ubiquitous transgene expression, Ixo-vec provides sustained aflibercept protein levels in non-human primate (NHP) ocular fluids out to 2.5 years after injection (Kiss, 2021) and in humans as demonstrated in the OPTIC trial. To improve our understanding of AAV vector genome (vg) distribution and mRNA expression, the per cell intraocular distribution of IVT-delivered Ixo-vec at 3E10 and 1E11 vg/eye (human equivalent dose (HED) 6E10 and 2E11 vg/eye) was evaluated in a GLP compliant 3 month-long study in Cynomolgus monkeys. The doses evaluated were well tolerated, with observations limited to dose-related non-adverse low-grade inflammation, and non-adverse infiltrates. The intraocular pressure in treated eyes was normal (≥14mm Hg) throughout the study. The no-observed-adverse-effect-level was established at 1E11 vg/eye dose (HED 2E11 vg/eye). The pattern of ocular expression was evaluated using BaseScope, an in-situ hybridization assay optimized to detect AAV vector genomes (vgs) and aflibercept mRNA in the eyes of NHPs. The assay utilized a probe designed against the engineered promoter for the detection of vgs, and a 1-ZZ paired probe flanking the splicing junction within the cassette promoter elements for the detection of aflibercept mRNA. The mRNA aflibercept-specific probe only generates a signal after the 5' UTR intron has been spliced, which allows for the precise detection of transgene mRNA without vector DNA interference. Evaluation of vg distribution identified widespread vg presence in anterior and posterior ocular tissues. In the retina, the presence of vector DNA was restricted to the macula and periphery, regions where the inner limiting membrane (ILM) are the thinnest. In these regions, cells of the retinal ganglion cell (RGC) layer, inner nuclear cell layer (INL), and photoreceptor (PR) layer contained vector DNA. In the mid-retina, where the ILM is the thickest, vgs were bound to the ILM and not found within the cells of the deeper layers of the retina. The presence of aflibercept mRNA correlated well with vg DNA that was present intracellularly. Aflibercept mRNA was identified in anterior and posterior tissues mirroring the intracellular presence of vgs. In the retina, the presence of transgene mRNA was restricted by the ILM to cells within the RGC, INL, and PR layers of the macula and periphery. Transgene mRNA was not detected in the mid-retina where the ILM is the thickest. The study demonstrated IVT administration of Ixo-vec at doses 3E10 and 1E11 vg/eye (HED 6E10 and 2E11 vg/eye) resulted in widespread distribution of aflibercept mRNA with the primary localization in the macula and peripheral retina. The results demonstrate widespread distribution of aflibercept mRNA expression across ocular cell types and regions of the eye does not result in adverse ocular changes and could contribute to the maintenance of durable therapeutic ocular aflibercept levels.

1558 Microfluidic Droplet Cell Mechanoporation Enables Highly Efficient Genome Editing in Human Primary Immune Cells

Byeongju Joo[1], You-Jeong Kim[2], Da Young Yun[3], Cheulhee Jung[3], Aram Chung[1,2]

[1]MxT Biotech, Seoul, Korea, Republic of,[2]School of Biomedical Engineering, Korea University, Seoul, Korea, Republic of,[3]Division of Biotechnology, Korea University, Seoul, Korea, Republic of

Cell-based therapy has shown compelling clinical evidence, and it has changed the paradigm of cancer treatment. A representative example of cancer immunotherapy includes chimeric antigen receptor-engineered T cell (CAR-T) therapy. In order for T cells to be given therapeutic activity, external genetic molecules such as mRNA, plasmid DNA, and CRISPR-Cas RNP must be internalized into T cells. For cell gene modification, benchtop methods such as viral transduction and electroporation have been widely used; however, these methods are

limited by high cost, low throughput, safety concerns, and/or loss of cell functions. To overcome these drawbacks, we present a microfluidic intracellular delivery platform for non-viral genome editing with microdroplet-enabled cell mechanoporation.

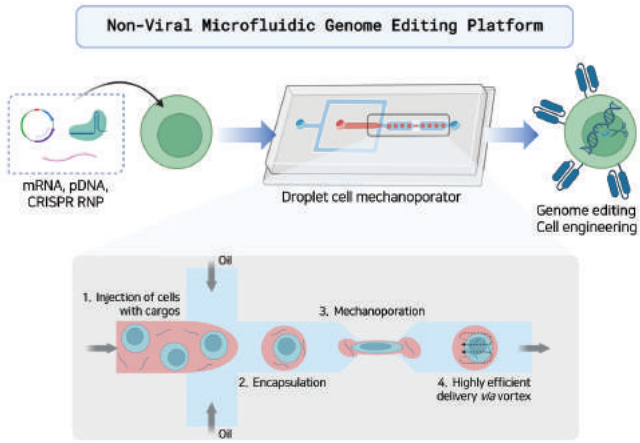

Figure 1. Schematic illustration of genome editing process *via* droplet cell mechanoporator.

In this approach, cells and target genetic materials are co-encapsulated into droplets, and when they go through a small constriction, mechanical cell stretching temporarily permeabilizes the cell membrane. The external cargos are internalized by recirculation flows developed in the droplet through the created membrane discontinuities, allowing for highly efficient delivery while maintaining high cell viability. With the use of our platform, we were able to internalize GFP-expressed mRNA and plasmid DNA with extremely effective cell transfection efficiency. By delivering CRISPR-Cas9 RNPs for non-homologous end joining (NHEJ), double NHEJ, and homology directed repair (HDR), we also demonstrated much greater genome editing efficiency compared with electroporation and lipofection. In summary, high delivery efficiency, high scalability, low analyte consumption, and low-cost operation for CRISPR-based genome editing were demonstrated, validating the high potential of the proposed platform for applications in cell-based therapies.

1559 Digital Droplet PCR Assay Robustness

Jeffrey Gagnon
Oxford Biomedica Solutions, Bedford, MA

Vector genome (VG) titer is arguably the most important critical quality attribute of a therapeutic AAV. Ideally, an accurate and precise VG titer method is used throughout the manufacturing process to ensure product quality, stability and, most importantly, clinical dosing decisions. Therefore, establishing a robust vector genome titer method early in AAV product development is absolutely essential. Through exhaustive development and optimization of a droplet digital PCR (ddPCR)-based method for vector genome titer, we consistently achieve inter-assay variability of < 15% for Phase 1 studies across multiple programs. This was achieved through the addition of automation, optimized primer/probe design and method workflow harmonization. A failure mode effect analysis was performed on the optimized method to identify critical method parameters and was followed by robustness testing to confirm accuracy and precision during these critical steps of the method. The end result is a robust VG titer method suitable for the entire product development lifecycle from pre-clinical through registrational studies.

1560 Development of a Gene Therapy for UBA5 Deficiency

Toloo Taghian, Sanjana Pulaparthi, John McCarthy, Tyler Mola, Aine C. Scholand, Erin Frances Hall, Julie Aguiar, Miguel Sena-Esteves, Heather L. Gray-Edwards
UMass Chan Medical School, Worcester, MA

Ubiquitin-like modifier activating enzyme 5 (UBA5) deficiency is an ultra-rare autosomal recessive neurological disorder. UBA5 is the E1 activating enzyme in a ubiquitin-like post-translational modification system called ubiquitin-fold modifier 1 (UFM1) cascade. Compound heterozygous mutations in UBA5 lead to disruption of UFM1 cascade and cause early infantile-onset encephalopathy; however, the role of UBA5 and UFM1 cascade in central nervous system is not understood. UBA5 patients present with infantile spasms, failure to thrive, hypotonia, developmental delay, and microcephaly. Patients develop movement disorders, have intellectual deficit, vision defects, epilepsy and some do not acquire language skills. Life span is variable. Currently there is no treatment for UBA5 deficiency. We designed self-complementary AAV9 vectors encoding UBA5 under four different promoters to determine the most effective transgene cassette to express UBA5 ubiquitously and restore function of UFM1 system. All vectors encode human UBA5 with a C-terminal HA tag. AAV vector functionality was confirmed by transient transfection of UBA5-knockout-HEK293T cells, which were generated by CRISPR/Cas9 genome editing. Our in-vitro results indicate all four vector constructs restore expression of UBA5 at higher-than-normal levels and importantly restore UFM1 system functionality.Considering that there is no viable mouse model of UBA5, we performed a biodistribution/safety study in wild-type mice by neonatal intracerebroventricular infusion of four different AAV9-UBA5 vectors. Mice were sacrificed at 6 weeks of age and western blot analysis confirmed UBA5 expression in the brain in all AAV-treatment groups. Importantly, AAV expressed UBA5-HA *in vivo* was shown to interact with its molecular partners to activate the UFM1 pathway. Next steps are to evaluate the functionality of the four AAV9-UBA5 vectors in UBA5 patient fibroblasts, followed by an FDA meeting around toxicology study design to establish safety prior to first-in-human clinical trials.

1561 Cell-Type Specific Reduction of Prion Expression in Neurons and Astrocytes Using Engineered Zinc Finger Transcriptional Regulators

Victoria Shih-Wei Chou[1], Kimberly Marlen[1], Qi Yu[1], Giulia Cisbani[2], Finn Peters[2], Garrett Lew[1], Meredith Mortberg[3], Chiara Melis[2], Finn Hartstein[2], Jing Hu[1], Swetha Garimalla[1], David Ojala[1], Sarah Hinkley[1], Alicia Goodwin[1], Mohad Mehrabian[1], Eric Vallabh Minikel[3], Sonia M. Vallabh[3], Amy Pooler[1], Bryan Zeitler[1]

[1]Sangamo Therapeutics, Inc., Richmond, CA,[2]Evotec, Hamburg, Germany,[3]Broad Institute of MIT and Harvard, Cambridge, MA

Prion disease is a fatal neurodegenerative disorder caused by misfolding and aggregation of the prion protein, PrP, encoded by the *PRNP* gene. Cellular PrP is ubiquitously expressed throughout the body and *PRNP* transcripts are abundant in both neurons and glia. Nevertheless, several lines of evidence from prion-infected mouse models suggest that neuronal PrP expression is necessary and sufficient for neurotoxicity and disease progression. We are developing a potential single administration therapeutic approach using zinc finger repressors (ZF-Rs) to lower the expression of brain PrP. To evaluate the contribution of different cell types to prion expression at the bulk and single-cell level in the brain, we generated AAV vectors expressing a highly potent and specific prion-targeted ZF-R under the control of one of three different promoters for neuron (hSYN1), astrocyte (GfaABC1D), or non-cell type specific (CMV) expression. In cultured mouse primary neurons and astrocytes, ZF-R treatment reduced *Prnp* mRNA in a dose-dependent manner. While hSYN1-driven expression was restricted to neurons, CMV- and GfaABC1D-driven expression were found in both cell types. In wildtype mice treated with these constructs, all tested promoters resulted in at least 50% bulk prion mRNA reduction (hSYN1 ≥ CMV > GfaABC1D) when compared to the control group. Brain hemispheres from the same experiment were analyzed by multiplexed RNAscope and immunohistochemistry, and cortex was analyzed by single-nucleus transcriptomics. For all promoters, a strong negative correlation between ZF-R and *Prnp* expression was observed at the single-cell level throughout the brain. Neuron-specific expression was observed for the hSYN1 promoter in all brain regions examined. For the CMV group, heterogenous expression was observed, primarily in neurons and astrocytes. In contrast to previous reports, the GfaABC1D promoter did not appear to drive expression in astrocytes, but rather in neurons, albeit more weakly than hSYN1. Hence, we initiated an effort to identify enhancers capable of brain-restricted expression in neurons and astrocytes. First, from existing mouse and human single-cell transcriptomic profiles, we identified genes that are expressed in both neurons and astrocytes but lack expression in liver. We then extracted putative upstream enhancer regions from the human orthologs into multiple distinct segments suitable for AAV packaging. AAV-promoter-ZF-Rs were screened in primary mouse cortical neurons, primary rat astrocytes, and human iPSC-derived astrocytes. Transduction efficiencies and promoter specificity were evaluated using confocal imaging for GFP reporter expression and RT-qPCR for ZF-R and *Prnp* expression. Top enhancer segments exhibited expression and potent *Prnp* reduction in both neurons and astrocytes. Based on these encouraging results, top candidates will be evaluated *in vivo* to assess cell-type and tissue-specific ZF-R expression, *Prnp* reduction, and CSF PrP knockdown.

1562 Treatment of Huntington's Disease by Inhibition of Caspase-6 Cleavage Using CRISPR Base Editing

Shraddha Shirguppe

Department of Bioengineering, UIUC, Urbana, IL

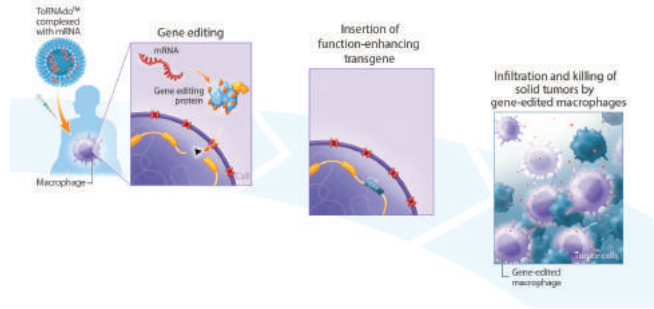
Huntington's disease (HD) is a neurodegenerative condition with autosomal dominant inheritance, characterized by a progressive decline in cognitive, motor, and behavioral features. HD is caused by the expansion of a polyglutamine-encoding 'CAG' repeat within exon 1 of the Huntington (HTT) gene which results in the formation of mutant protein aggregates that are mainly toxic to the cells in the striatum and cortex regions of the brain, consequently leading to neuronal loss and dysfunction. Current treatments for HD are purely symptomatic and hence there is a need for therapies targeting the underlying genetic defect. Although CRISPR Cas systems have been utilized to induce targeted modifications in genomic DNA, their reliance on creating double stranded breaks (DSBs) in DNA to achieve editing is a limitation to their use from a therapeutic standpoint. Moreover, directly correcting the disease-causing mutation is complicated due the repetitive nature of the mutation causing HD and a non-allele specific reduction of HTT expression is undesirable because the functions of the wild-type HTT protein are not well understood. Studies have shown that cleavage of the mutant HTT (mHTT) protein at the predicted caspase-6 binding site encoded by HTT exons 12-13, plays a key role in HD pathogenesis. Caspase-6 cleavage of mHTT generates highly toxic N-terminal and C-terminal derivatives that are responsible for the development of symptoms characteristic of HD. In this work, we utilized CRISPR-SKIP, a base editing strategy to induce permanent exon skipping by introducing C>T or A>G mutations at the conserved splice acceptor site in genomic DNA, to exclude the Caspase 6 binding domain from mature mRNA HTT transcripts. First, we characterized the editing outcomes of base editors that disrupt the consensus splice acceptor of HTT exon 13 in cultured human cells and analyzed the patterns of mRNA expression leading to the removal of Caspase 6 cleavage site. Next, we utilized split-intein base editing technology to deliver the base editing systems into the striatum of YAC128 HD mouse model using AAV9. Our approach successfully mutated the splice acceptor of HTT exon 13 in vivo and facilitated the survival of these edited neurons. Moreover, we also report a preservation of brain volume and decreased levels of toxic mHTT inclusions in the striatum at 18 months of age in the BE- treated transgenic mice- a promising in vivo therapeutic outcome that supports further development of this technology for the treatment of HD. Overall, our work supports the potential of AAV-encoded split BEs for the treatment of Huntington's disease.

1563 mRNA Cell Engineering Enables Rapid Prototyping of Macrophage Gene-Editing Strategies for Cancer Immunotherapy Applications

Ian Hay, Abigail Blatchford, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

Macrophages' ability to infiltrate solid tumors and engage in both direct killing of cancer cells and recruitment of other immune cells has made them a promising target for development of next-generation cancer immunotherapies. The innate ability of macrophages to ingest foreign genetic material also facilitates their engineering with formulated nucleic acids, including mRNA. The oncoantigen tyrosine-protein kinase transmembrane receptor ROR1 has garnered interest for its minimal expression in healthy adult cells and overexpression in many malignancies, including solid tumors associated with ovarian, lung, and triple-negative breast cancer. Here, we present an mRNA-based platform for rapid prototyping of macrophage engineering approaches. We show mRNA delivery to peripheral blood mononuclear cell (PBMC) and iPS cell-derived macrophages for gene editing prototyping and functional assessment of encoded proteins. To develop this platform, we transfected macrophages with unmodified or 5'-methoxyuridine (5-moU)-containing mRNA encoding green fluorescent protein (GFP). Both mRNAs resulted in more than 95% of cells displaying GFP within 4 hours. We next designed an ROR1-targeting CAR with a CD3 zeta activation domain and 4-1BB costimulatory domain. Transfection of mRNA encoding the ROR1-CAR yielded 70% CAR-expressing cells, as measured using PE-labelled ROR1. We then compared ROR1 affinity of rabbit and humanized binding domains and found that the humanized binding domain displayed a 2.5-fold increase in affinity as measured by flow cytometry using PE-labelled ROR1. The human receptor domain, but not the rabbit domain, demonstrated activation when bound to ROR1 as assessed by immunofluorescence of CD3 zeta phosphorylation. We also assessed the mRNA-encoded ROR1-CAR's functionality by measuring killing of ROR1-expressing SKOV-3 ovarian cancer cells. Both the rabbit and humanized ROR1 domains of the CAR displayed significantly increased cytotoxicity towards SKOV-3 cells when compared with untransfected macrophages after a 24-hour co-culture at a 5:1 effector-to-target ratio ($p<0.01$). We then inserted the ROR1-CAR sequence into the AAVS1 safe harbor locus of iPS cells under the control of an SFC promotor, isolated 5 biallelic-inserted lines, and differentiated them into macrophages. These results demonstrate an mRNA-based platform for rapid prototyping of macrophage engineering approaches. Transfection of macrophages with mRNA encoding a chimeric antigen receptor (CAR) targeting ROR1 resulted in functional expression *in vitro*, facilitating optimization of the antibody and co-stimulatory domains to improve protein binding affinity and immune activation. This platform thus enables the assessment and validation of novel macrophage gene editing strategies and is being explored for the development of macrophage-engineering therapies for solid tumor applications.



1564 *Ex Vivo* Prime Editing Corrects the Sickle Cell Allele in Hematopoietic Stem Cells and Corrects Disease Phenotypes in Mice

Kelcee A. Everette

Department of Chemistry and Chemical Biology, Harvard University, Cambridge, MA

Sickle cell disease (SCD), a deadly monogenic disorder affecting millions of individuals, is caused by an A•T-to-T•A transversion mutation in the β-globin gene (*HBB*). We optimized a prime editing system to directly correct the SCD allele (HBB^S) to the wild-type allele (HBB^A) with high ratios of the desired edit to indel byproducts. Sickle cell patient hematopoietic stem and progenitor cells (HSPCs) electroporated with PEmax mRNA, an engineered pegRNA (epegRNA), and a nicking single-guide RNA (sgRNA) yielded up to 41% conversion of HBB^S to HBB^A. Seventeen weeks after transplantation of prime edited HSPCs into immunodeficient mice, high-level correction of HBB^S was maintained in all donor-derived cells with no alterations detected in the frequency of engraftment, hematopoietic differentiation, or lineage maturation compared to unedited healthy donor HSPCs. On average, 42% of human erythroblasts and reticulocytes isolated 17 weeks after transplantation of prime-edited HSPCs from four SCD patient donors contained monoallelic or biallelic *HBB* correction, exceeding the levels predicted to be required for therapeutic benefit in patients. Red blood cells derived from prime-edited SCD HSPCs contained significantly reduced levels of sickle hemoglobin (HbS), had a proportionate increase in normal adult hemoglobin (HbA) of up to 42%, and were resistant to hypoxia-induced sickling. An extensive analysis of over 100 candidate off-target sites nominated by an unbiased genome-wide experimental approach detected minimal off-target editing from all prime editing components used for the corrective edit. Our findings represent one of the first PE-based therapeutic strategies for HSCs, suggesting the potential of a one-time treatment for sickle cell disease that directly corrects pathogenic HBB^S to wild-type HBB^A, does not require delivery of any viral or non-viral DNA template, and minimizes undesired consequences associated with DNA double-strand breaks.

1565 Development of a Self-Complementary AAV.U7snRNA Vector for Efficient Dystrophin Exon 53 Skipping

Randolph Qian, Steven J. Foltz, Lan Jin, Ting Chen, Chunping Qiao, Kirk W. Elliott, Ikram Hafiz, Jason Yang, Subha Karumuthil-Melethil, Joseph T. Bruder, Olivier F. Danos, Ye Liu

Research & Early Development, REGENXBIO, Rockville, MD

Duchenne Muscular Dystrophy (DMD) is a genetic disease caused by mutations in the *DMD* gene, encoding dystrophin. Of these mutations, roughly 80% are amenable to exon skipping, a therapeutic approach in which specific exon(s) are excluded from the mature *DMD* mRNA to restore the open reading frame disrupted by mutations. The result is a nearly full length and functional dystrophin protein. Here, we describe development of AAV.3XU7.Ex53, a self-complementary (sc) AAV vector expressing three antisense sequences on a modified U7 small-nuclear RNA (snRNA) scaffold that achieves efficient skipping of dystrophin exon 53 *in vitro* and *in vivo*. Multiple anti-sense sequences were designed to target exonic splicing enhancer sequences in intron 52 and exon 53, and the splice acceptor site in intron 52. Chosen antisense sequences were linked to a modified U7 snRNA and cloned into an AAV.U7 cassette plasmid. Sequences were tested for skipping efficiency with plasmid transfection, and the top sequences were packaged into AAV for further evaluation. AAV vectors expressing a single U7 snRNA induced modest levels of exon 53 skipping in cultured human rhabdomyosarcoma (RD) cells, as assayed by digital droplet PCR. However, the combination of two separate U7 snRNA cassettes into one AAV vector synergistically increased exon skipping efficiency, which was further amplified with the addition of a third unique U7 snRNA cassette. The final construct, AAV.3XU7.Ex53, demonstrated efficient exon 53 skipping of up to 90% in RD cells with comparable expression of all three U7 snRNAs. Analysis of vector genomes from AAV.3XU7.Ex53 vector preps via TapeStation and PacBio long read sequencing revealed high quality genome integrity, indicating the repeated U7 cassettes and hairpins within the snRNA did not negatively impact the packaging of full length scAAV genomes. Given our promising *in vitro* data, we performed an *in vivo* proof-of-concept study in hDMDdel52/*mdx* mice, which express human *DMD* without exon 52 and are amenable to exon 53-skipping therapies. Four weeks post AAV infusion, skipping efficiency of exon 53 in heart was 70% (low-dose) and 85% (high-dose), which corresponded to 31.0% and 59% of wildtype (C57Bl/6J) levels of dystrophin protein, respectively. In the gastrocnemius, 36% (low-dose) and 61% (high-dose) skipping resulted in 11% and 30.4% of wildtype protein. Analysis of skeletal muscle histopathology with Sirius red and embryonic myosin heavy chain immunofluorescence revealed that fibrosis and muscle regeneration were significantly reduced at either dose compared to mice treated with a scramble U7 snRNA vector. Together, these data demonstrate the potential of AAV.3XU7.Ex53 as a therapy for DMD patients amenable to exon 53 skipping.

1566 Development of CRISPR-Cas12f Gene Therapy for Androgenic Alopecia via Targeting of SRD5A2 Gene

Suyeon Kang[1], Seunghun Kang[1], Taegeun Bae[2], Junho Hur[3]

[1]Graduate School of Biomedical Science & Engineering, Hanyang University, Seoul, Korea, Republic of,[2]College of Pharmacy, The Catholic University of Korea, Gyeonggi-do, Korea, Republic of,[3]Department of Genetics, Hanyang University, Seoul, Korea, Republic of

Androgenic alopecia is a common form of hair loss that can lead to baldness and requires medical attention. A major cause of androgenetic alopecia is a conversion of testosterone (TS) to dihydrotestosterone (DHT) by the enzymatic activity of steroid type II 5-alpha-reductase (SRD5A2). Excessive conversion of TS to DHT by SRD5A2 causes damage to hair dermal papilla cells (DPC) that leads to apoptosis of hair DPC and male-pattern hair loss. Accordingly, SRD5A2 has been a major target for androgenic alopecia therapy, and there have been attempts of therapeutic applications of CRISPR-Cas9 systems to target SRD5A2. While Cas9 is an effective genome editing system that is commonly utilized, its large gene size is one of the technical problems for in vivo delivery via virus. To address the delivery issue, we sought to develop SRD5A2 targeting genome editing by Cas12fl, of which the compact size enables efficient delivery by virus like AAV. Furthermore, we intended to deliver CRISPR-Cas system via AAV virus and lipid nanoparticle, that can deliver to mouse by intradermal injection. To this end, we conducted SRD5A2 gene knock-out in HEK293, human DPC, and NIH3T3 via delivering Cas12fl by plasmid vectors and lentiviral delivery system. We observed that delivery of Cas12fl to human cells and mouse cells induced significant indel frequencies comparable to that of Cas9. Our results suggested that CRISPR-Cas12f system can be utilized for genome editing of SRD5A2 as a mean to develop therapeutics against androgenic alopecia treatment.

1567 Developing and Characterizing an AAV Transgene Cassette That Expresses eCD4-Ig and TPST2

Isai Leguizamo[1], Peter Koroma[1], Matthew Gardner[2]

[1]Division of Microbiology and Immunology at the Emory National Primate Research Center, Emory University, Atlanta, GA,[2]Division of Microbiology and Immunology at the Emory National Primate Center, Emory University School of Medicine, Atlanta, GA

The development of antiretroviral therapy (ART) has significantly prolonged the lifespan of people living with HIV-1. Despite the various ways ART works to prevent viremia, infected individuals still harbor latently infected CD4+ T cells that serve as viral reservoirs. Recent advancements in gene therapy have demonstrated promising results which may be used to treat HIV-1. One of many gene therapy delivery systems is the use of adeno-associated virus (AAV) vectors which have shown to efficiently deliver and express anti-HIV inhibitors and antibodies. Our previous work developed and characterized the anti-HIV inhibitor, eCD4-Ig which contains very broad and potent neutralizing features and the ability to elicit effector functions. eCD4-Ig is composed of the CD4 immunoglobulin domains 1 and 2, an antibody Fc domain, and a tyrosine-sulfated coreceptor-mimetic peptide which mimics the coreceptor of all HIV-1 and simian immunodeficiency

virus (SIV) isolates. Sulfation of the coreceptor-mimetic peptide is mediated by the enzyme TPST2. Due to its ability of binding to conserved regions of Env, eCD4-Ig efficiently neutralized 100% of a diverse panel of neutralization-resistant HIV-1, HIV-2, and SIV isolates. AAV-expressed eCD4-Ig provided durable protection to rhesus macaques after challenges with SHIV-AD8 or SIVmac239. Additionally, we were able to sustain expression of eCD4-Ig for over a year. Despite observing sustained eCD4-Ig expression in vivo, reaching therapeutic concentrations of eCD4-Ig remains a challenge. The initial work for expression of eCD4-Ig and TPST2 consisted of using two separate AAV vectors, each containing a single transgene cassette. Our new strategy uses a single AAV vector that expresses eCD4-Ig and TPST2 from a single transgene cassette. Initially, we engineered three different transfer plasmids, either containing a bi-directional dual promoter (BiPro), tandem promoter (TanPro), or a combination of a single promoter along with a cricket paralysis virus (CrPV) IRES. We performed an anti-sulfation ELISA on eCD4-Ig to determine the sulfation efficiency across the different cassette designs and observed no difference in sulfation efficiency, regardless of cassette design. We then assessed the potency of these variants through TZM-bl neutralization assays against several HIV-1 isolates. All newly engineered cassettes showed no decrease in potency against the selected HIV-1 isolates when compared to eCD4-Ig protein made from a two-vector approach. Next, we engineered six additional transgene cassettes utilizing the BiPro design. These expression cassettes include different promoters, stacked enhancers, and introns. When we assessed sulfation efficiency by ELISA, we observed higher efficiency for three of the five optimized BiPro designs. All newly engineered cassettes resulted in eCD4-Ig proteins with no decrease in potency or demonstrated improved potency against the selected HIV isolates when compared to eCD4-Ig protein from the first BiPro construct, suggesting that each protein was sufficiently sulfated for neutralization. Finally, we assessed eCD4-Ig expression in Balb/6 mice for two BiPro designs. Two cohorts of four mice were intramuscularly administered an AAV9 vector encoding one of the new BiPro designs. Our data show that eCD4-Ig expression varies between the two vectors with the best having a peak expression of 40 $\mu g/mL^{-1}$. Future mouse studies will focus on assessing expression of the remaining BiPro cassettes and further optimization will be made on the transfer cassette that results in the highest concentrations of eCD4-Ig.

1568 Adenovirus Type 34 and HVR1-Deleted Adenovirus Type 5 Do Not Bind to PF4: Clearing the Path towards Vectors without Thrombosis Risk

Erwan Sallard[1], Daniel Pembaur[1], Alexander Thomas Baker[2], Lucie Bouard[2], Katrin Schröer[1], Sebastian Schellhorn[1], Nissai Beaude[1], Georgia Koukou[1], Natascha Schmidt[1], Wenli Zhang[1], Florian Kreppel[1], Anja Ehrhardt[1]

[1]ZBAF, Witten/Herdecke University, Witten, Germany,[2]Accession Therapeutics Limited, Oxford, United Kingdom

Introduction: The adenoviral vector (Ad) based AstraZeneca and Janssen COVID vaccines have been associated with rare cases of vaccine-induced thrombotic thrombocytopenia (VITT, also known as TTS), a condition which depends on Ad binding to the blood protein Platelet Factor 4 (PF4). Harnessing the broad diversity of natural Ads, we strived to identify Ad types with low or absent affinity for PF4. Furthermore, we attempted to locate the binding site of PF4 on the capsid of the frequently vectorized Ad type 5 (Ad5) and construct modified vectors with ablated PF4 binding. Methods: We established an armamentarium of techniques including ELISA-qPCR and Aggregate Pull-Down (APD), which enabled fast and sensitive assessments of virus-protein interactions and could replicate already published results about PF4 binding of vaccine-like Ads. We used these techniques to screen dozens of types from various Ad species, and Ad type 5 (Ad5) derived vectors carrying genetic or chemical modifications of different hexon hyper-variable regions (HVR). The PF4 binding affinity of the main candidates was accurately measured by SPR. Results: Unlike most tested types, Ad34 did not bind to PF4. Likewise, the deletion or shielding through PEGylation of the HVR1 loop of Ad5 seemingly ablated its PF4 binding. We swapped the HVR1 loop of Ad5 and Ad34 to confirm that this region determines PF4 binding ability. Finally, we observed that interactions with PF4 increase Ad binding to erythrocytes and epithelium-derived cell lines, suggesting that PF4 may influence the tropism of vaccines in undesired ways. Conclusions: PF4 binds to Ad hexon through interactions dependent on HVR1. PF4 binding can be ablated by HVR1 deletion or exchange or through the vectorization of non-canonical Ad types. These findings open the way for the development of safer vectors for vaccine or gene therapy with decreased or suppressed risk of VITT.

1569 AAV Mediated Lysyl Oxidase Gene Therapy Improved Corneal Stromal Status: Application for Keratoconus

Subhradeep Sarkar[1], Rohit Shetty[2], Arkasubhra Ghosh[1]

[1]GROW Laboratory, Narayana Nethralaya Foundation, Bangalore, India,[2]Cornea Department, Narayana Nethralaya, Bangalore, India

Keratoconus (KC) is a progressive, corneal ectatic disorder caused by aberrant extracellular matrix (ECM) degeneration that reduces visual acuity and requires corneal transplant in severe forms. The disease primarily affects patients below age 40, estimated to affect 2.3% of people in India, causing significant morbidity. Lysyl oxidase (LOX), an endogenous collagen crosslinking enzyme is known to be reduced in the KC patient corneas, along with reduced collagens and increase ECM-degrading enzymes such as matrix metalloproteinases (MMP9) and inflammatory factors. Lack of collagens and crosslinking leads to corneal thinning and protrusion, hence current clinical interventions are dependent on surgical methods of stiffening the cornea or transplanting them, which are associated with many complications including a lack of donor corneal tissues. There is an unmet clinical need for efficient, long term, therapeutic strategies for treatment of KC. Enhancing LOX enzyme levels therefore can lead to efficient crosslinking of collagen fibrils, thereby lending stiffness and structural integrity in the cornea. We therefore developed a LOX expressing AAV vectors driven by CMV and Tetracycline responsive promoter which was further packaged in AAV9 capsids and investigated the effects of augmented LOX expression in corneal tissues using in vitro, in vivo and ex vivo models. We transduced primary human corneal fibroblast (HCF) from healthy and KC donors with AAV9-LOX. Immunoblotting was performed to assess the changes in the expression pattern of ECM proteins (LOX, type I and IV collagens, fibronectin, CTGF) and

MMP9. Increased levels of LOX led to the subsequent reduction in the MMP9 levels and a significant increase in various collagen proteins in both healthy and KC patient HCFs. We functionally validated this in a collagen gel contraction assay, which showed an increased contraction with media supernatants from cells transduced with AAV.LOX, indicating an increased level of collagen crosslinking by the secreted LOX protein. We further tested the effect of ectopic LOX expression from topically administered AAV9.LOX vectors in c57/bl6 mouse (N=6) corneas. Gene expression and immunofluorescence staining studies demonstrated that AAV.LOX transduction significantly decreased (4.5-fold) the MMP9 levels ($p< 0.01$) compared to AAV9.eGFP control transduced eyes. Similarly, collagen I and IV increased by 5.7-fold and 2.9-fold respectively compared to AAV9.eGFP control ($p< 0.01$). No ocular or corneal adverse events were noted in the mouse eyes treated with our vectors. Lastly, we carried out ex vivo studies by intrastromal injections of AAV9.LOX vectors in donor human whole eye globes and also transduced AAV9.LOX vectors in donor human corneal lenticules from SMILE surgeries (N=6). IHC analysis post intrastromal injection of AAV9.LOX virus showed a significant increase in LOX protein expression in the corneal stroma in comparison to the control eye upon histological analyses. An increase in collagen levels in the corneal stroma was also validated using Masson's trichrome staining. The human corneal lenticules recapitulated the same findings as the whole globe analysis. Taken together, the data indicate that augmentation of LOX via AAV-mediated gene therapy can improve the biomechanical stability of the cornea by enhancing the ECM content which has potential for clinical application.

1570 CD46 and CD59 Inhibitors Additively Enhance Complement-Dependent Cytotoxicity of Anti-CD38 mAbs Daratumumab and Isatuximab in Human Multiple Myeloma Cells

Theo Koob[1], Ajay Gopal[1], Darrick Carter[2], Andre Lieber[1], Hongjie Wang[1]

[1]University of Washington, Seattle, WA,[2]PAI Life Sciences, Seattle, WA

Multiple myeloma (MM) is an incurable malignancy of the B-cell lineage, characterized by neoplastic, monoclonal expansion of plasma cells in the bone marrow. Remarkable progress has been made in the treatment of MM with the anti-CD38 monoclonal antibodies such as Daratumumab and Isatuximab, which can kill MM cells through the induction of complement-dependent cytotoxicity (CDC). The CDC efficacy of Daratumumab and Isatuximab is however limited by membrane complement inhibitors, including CD46 and CD59, which are upregulated in MM cells. We recently developed a small recombinant protein (Ad35K++) capable of blocking CD46 and sensitizing tumor cells to anti-CD20 mAb triggered CDC (e.g Rituximab and Ofatumumab). Here we tested Ad35K++ in combination with Daratumumab and Isatuximab. We show that Ad35K++ increases the CDC efficacy of Daratumumab and Isatuximab on Burkitt's lymphoma and MM cell lines (MOLP8, SUDHL-8, EJM). Ad35K++ salvaged the efficacy of Daratumumab and Isatuximab at subtherapeutic ("low") doses in MM lines. We also tested a small recombinant protein that targets CD59 (rILYd4) in combination with Daratumumab and Isatuximab on MM cells. rILYd4 also increased CDC killing of MM cells by Daratumumab and Isatuximab. The combination of Ad35K++ and rILYd4 additively enhanced the CDC effect of Daratumumab and Isatuximab. Daratumumab and Isatuximab treatment of MM lines (without Ad35K++ or rILYd4) resulted in the upregulation of CD46/CD59 and/or survival of $CD46^{high}$ / $CD59^{high}$ MM cells which escaped a second round of Daratumumab and Isatuximab treatment. Escape in the second treatment cycle was prevented by combining Daratumumab with Ad35K++ / rILYd4, whereby both co-therapeutics had an additive effect on Daratumumab0induced CDC. Studies with patient MM cells will be reported. Overall, our data demonstrate that Ad35K++ and rILYd4 are efficient co-therapeutics of Daratumumab and Isatuximab, specifically in multi-cycle treatment regimens, and could be used to improve the treatment of multiple myeloma.

1571 Optimization of Lentiviral Vector Mediated Transduction of T Cells for Clinical Use

Giuliana Vallanti, Margherita Neri

AGC Biologics, Milan, Italy

Genetic modification of T cells represents a straightforward technology to generate cell-therapy-based drugs, which showed promising clinical efficacy in cancer patients. Indeed, we demonstrated the feasibility of retroviral and lentiviral vector-genetically modified T cells production for commercial use as well as their clinical efficacy. Lentiviral vectors (LVV) are a platform to deliver and permanently express therapeutic genes and have displayed great potentiality in clinical trials. Here we present proof of concept results concerning the setting up of optimal T-cell transduction conditions with a highly-purified VSV-G pseudotyped LVV encoding for a CD44v6-CAR construct in order to obtain higher cell transduction efficiency and process yields. Briefly, donor-derived peripheral blood cells were activated with anti-CD3-anti-CD28 nanomatrix and cultured in chemically defined T-cell medium supplemented with interleukin-7 (IL-7) and interleukin-15 (IL-15). Different CD3/CD28-based activators and T cells specific serum free media were tested to define the best protocol for T cells activation and expansion. Transduction was performed after 24 hours or 48 hours, with MOI from 2 to 6 and cells were maintained in culture up to nine days. Optimized conditions were studied, Retronectin did not significantly improve the transduction rate of LVV. In addition, the small scale protocol was scaled-up in to a GMP-compliant environment . In particular, to this end, it was investigated the introduction of G-Rex platform for the cell expansion.

1572 Promoterless AAV Gene Targeting Vectors Favor Integration into the Albumin Locus Regardless of Homology Arm Sequences

Katja Pekrun, Calvin Stephens, Feijie Zhang, Hagoon Jang, Francesco Puzzo, Patricia Liehr, Aranyak Goswami, Mark A. Kay

Departments of Pediatrics and Genetics, Stanford University, Stanford, CA

The GeneRide technology utilizes homology dependent integration of a promoterless AAV vector (AAV-HR) into the highly transcriptionally active *Albumin* locus, thus enabling sustained transgene expression in the growing liver. Transgene expression from on-target integrated

vectors is driven by the endogenous *Albumin* promoter generating a fusion transcript that is subsequently translated into the albumin protein and the transgene protein due to the incorporation of a P2A skipping sequence between the last coding exon of *Albumin* and the transgene. Here, we investigated AAV-HR mediated targeting to alternative genomic loci. We designed human Factor IX (huFIX) AAV-HR vectors with homology arms targeting the *Alb*, *ApoE* and *Gapdh* genes. Since a short sequence included in older versions of AAV ITR backbone vectors just upstream of the right ITR has been described to contain cryptic promoter activity (Logan et al., 2017), we cloned all constructs into an ITR backbone vector lacking this sequence. We used the original *Alb*-F9 vector (Barzel et al., 2015) that harbors the cryptic promoter sequence as a control (*Alb*-F9^{+c}). We also compared two *Albumin* AAV-HR vector designs, one with a 1.3kb left and a 1.4kb right homology arm identical to the original vector design (*Alb*-F9) and one with a shortened left homology arm (1kb) and a longer right arm (1.6kb), termed *Alb*^{m}-F9. B6 mice were infused with the different AAV-HR vectors and underwent partial hepatectomy 5 weeks post vector administration to reduce non-integrated episomal vectors. Plasma huFIX expression in the *ApoE*-F9 and the *Gap*-F9 groups was lower than in the *Alb*-F9 group. However, the group of mice that had been injected with the *Alb*^{m}-F9 vector showed higher expression levels initially followed by a drop at about 4 weeks. Due to the shortened left homology arm as compared to the original *Alb*-F9 vector a putative CTCF-only Cis regulatory element is absent in this vector design, possibly contributing to episomal expression. The *Alb*-F9^{+c} AAV-HR vector injected mice also showed a modest decline of initially high transgene expression following partial hepatectomy, thus confirming that the cryptic promoter sequence drives episomal expression. To evaluate if the AAV-HR vectors had integrated into the intended loci, mouse livers were harvested 12 weeks post vector administration and transcripts fused to the transgene on the 5' end were amplified using 5'RACE followed by high-throughput Oxford Nanopore sequencing. For each injection group 2-4 animals were analyzed in 5'RACE with a sequencing depth of 300,000 - 500,000 reads for each animal. We found that while the majority of 5'RACE transcripts obtained from mice injected with the AAV-HR *Albumin* targeting vectors were fused to the expected *Albumin* exons upstream of those encoded by the rAAV vector (Exons 13 and CDS of Exon 14), the other AAV-HR constructs resulted in transgene transcripts that were primarily fused to *Albumin* or other gene derived exons. We subsequently designed a huFIX AAV-HR vector containing random DNA instead of homology arms (RD-F9) as well as an AAV-HR vector with homology arms containing human *ALBUMIN* sequences *(huALB*-F9) and injected those constructs into mice. No transgene expression was observed in the mice that had received the RD-F9 AAV-HR construct while huFIX expression in the *huALB*-F9 injected mice was comparable to the levels seen in the *Alb*-F9 injected mice. 5' RACE as well as qRT PCR showed that a considerable number of transcripts were fused to *Albumin* exon 12 despite very low homology between human and mouse *Albumin* genomic sequences. These results suggest that *non-Albumin* AAV-HR vectors tend to integrate off target into the *Albumin* locus.

1573 Ribitol Supplementation Expands the Therapeutic Window of BET Inhibitor JQ1 for Triple Negative Breast Cancer

Ravi Doddapaneni
Atrium Health, Charlotte, NC

Bromodomain and extraterminal inhibitors (BETi) are promising cancer therapies, yet prominent side effects have been reported in phase I clinical trials. JQ1 is the most thoroughly studied BETi that binds competitively to acetylated lysines and thus displaces BRD4 from binding to chromatin. JQ1 inhibits cancer cell proliferation, and this action involves downregulation of the rate-limiting enzymes of glycolysis, such as hexokinase 2, phosphofructokinase, and lactate dehydrogenase A. We recently reported that pentose sugar ribitol can upregulate glycosylation of alpha-dystroglycan (a-DG) with the potential to inhibit cancer cell proliferation and migration. Our following-up study by metabolomics revealed that ribitol can alter glycolysis in breast cancer cells. Here we investigate the combinatorial effects of ribitol and several other anticancer drugs including the bromodomain inhibitor JQ1 in breast cancer cells (MDA-MB-231, MCF-7 and T-47D) by cell survival assays and metabolomics. Different types of breast cancer cells were treated with each drug and in combination. All drugs alone showed limited inhibitory effect on cancer cells with the doses used. Combination of ribitol with the drugs such as chrysin, lonidamine, GSK2837808A, CB-839, and shikonin did not show additive effect. However, ribitol supplementation lowered the effective dose of JQ1 needed to successfully inhibit growth of the triple negative (MDA-MB-231) breast cancer cells compared to other types of breast cancer cells. Further, the combination of ribitol and JQ1 significantly inhibited the migration of triple negative breast cancer cells compared to either agent alone. Metabolomics and western blot data revealed that ribitol and JQ1 downregulate c-Myc levels leads to decreased activity of pyruvate kinase, glycolysis, and glutamine uptake. Further, the combination of ribitol and JQ1 increased the p53 levels leading to metabolic changes and apoptosis in the breast cancer cells. Altogether, these metabolic alterations of breast cancer cell mediated by ribitol and JQ1 result in a strong induction of apoptosis and inhibition of cell growth. Furthermore, ribitol supplementation might help reduce the severe side effects that arise from BETi therapy by reducing the dosage necessary for treatment. On the basis of our findings, further study is required to define biomarker(s) for targeted patient population for clinical trials with ribitol as an enhancer to BETi treatment. This study shows that metabolic reprogramming presents new avenues for developing targeted therapies to cancers with metabolites, especially in combination with other drug treatments and provides a possible clinical solution to challenges arising from the dose-dependent side effects of this class of epigenetic therapy.

1574 Early Changes in Liver Transcriptomic Profiles Following Adeno-Associated Viral Gene Therapy in the Severe Hemophilia A Dog Model

Mohamed Ismail Ashrafali[1], Batty Paul[2], Aomei Mo[2], Bridget Yates[1], Lori Harpell[2], Alexandre Menard[3], Pender Abbey[2], Naureen Khattak[1], Lisa Razon[1], A. Winterborn[2], Sylvia Fong[1], David Lillicrap[2]

[1]BioMarin Pharmaceutical, Novato, CA,[2]Queen's University, Kingston, ON, Canada,[3]Kingston Health Sciences Center, Kingston, ON, Canada

Background: Recombinant adeno-associated virus vectors (rAAV) are a major gene therapy platform for treatment of monogenic disorders, including hemophilia A. Valoctocogene roxaparvavec (AAV5-HLP-hFVIII-SQ) is an AAV5 vector delivering B-domain-deleted (BDD) human FVIII transgene controlled by a hybrid liver-selective promoter. In a phase 3 trial, a single treatment of AAV5-HLP-hFVIII-SQ (6e13 vg/kg) provided therapeutic expression of FVIII and bleeding control in adult severe hemophilia A patients. However, the mechanistic basis of transaminitis, variability and durability observed in clinical trial participants are not clear. Understanding the molecular changes in the liver are critical to identify appropriate immune modulatory strategies for safety, efficacy, and long-term durability of AAV gene therapy. **Aim:** To investigate liver gene expression profiles before and after AAV5-HLP-canine-BDD-FVIII (cFVIII) administration in a severe hemophilia A dog model. **Methods:** Nine severe hemophilia A dogs received one of three vectors (non-codon-optimized AAV5-HLP-cFVIII-SQ, codon-optimized AAV5-HLP-cFVIII-SQ and AAV5-HLP-cFVIII-V3 at 6.0e13 - 2.0e14 vg/kg). Liver biopsies were collected at baseline and 3 months after vector administration. FVIII activity (FVIII:C) was measured by one-stage FVIII (OSA) assay using a pooled normal canine plasma standard. Liver cFVIII DNA and RNA levels were quantified using ddPCR. Transcriptomic profiling was performed by RNA-seq followed by pathway enrichment analysis. Cellular immune response in the peripheral blood mononuclear cells (PBMC) was evaluated using an IFN-γ ELISPOT assay. **Results:** Dose-related FVIII expression was observed in dogs treated with the codon-optimized vectors, with significant correlation between liver vector DNA and circulating FVIII:C (**Figure 1**). Dogs treated with codon-optimized cFVIII vectors demonstrated enhanced transgene expression compared to non-codon-optimized vector. No IFN-γ response was detected in PBMC. Transcriptomic profiling of liver biopsies demonstrated enrichment of integrin pathways, immunological gene signatures for B cells and plasmacytoid dendritic cells (pDCs), and common dendritic cells at 3 months compared to baseline (**Table 1**). Expression of inflammatory cytokines involved in NK-cell and T-cell activation were also enriched. **Conclusions:** Our data suggests that mild activation of B cells, dendritic cells, NK-cell, and T-cells with an inflammatory cytokine response occurred in the liver of AAV5-HLP-cFVIII treated dogs 3 months post gene transfer; albeit without transaminitis. Transcriptomic profiling of PBMCs is ongoing to compare to liver profiles to better understand kinetics of immune responses to rAAV.

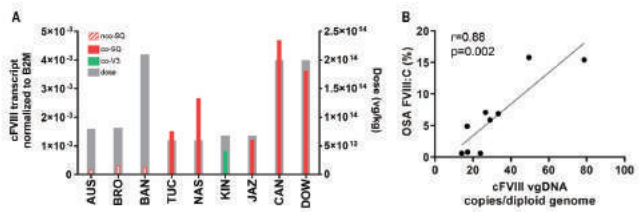


Figure 1. AAV5-cFVIII expression and activity in severe hemophilia A dogs at 3 months. A) AAV5-cFVIII mRNA transcript levels, and B) correlation between liver vector DNA and OSA FVIII:C, one-stage FVIII clotting assay (canine normal pooled standard) with a lower limit of detection of 2%. co, codon optimized; nco, non-codon optimized; SQ and V3, B-domain-deleted FVIII variants.

Enriched Gene Set	p-value	FDR-adjusted p-value	No. of genes in term	No. of genes that were regulated following AAV5-HLP-cFVIII treatment	No. of up-regulated genes	No. of down-regulated genes	Normalized Gene Set Enrichment Score (NES)
Integrin pathway	0.00058	0.034	22	3	3	0	1.47
B cells and plasmacytoid dendritic cells	3.40E-06	0.014	168	10	9	1	1.80
Common dendritic cells	1.00E-05	0.020	187	10	8	2	1.49
Cytokine production	7.00E-06	0.015	668	19	16	3	1.56

Table 1: Gene set enrichment analysis comparing AAV5-HLP-cFVIII vectors administered to hemophilia A dogs at 3 months and baseline (treatment vs control). A normalized gene set enrichment score (NES) determines whether a gene set is positively regulated or negatively regulated and an NES with Benjamini-Hochberg adjusted *P* value <0.05 was considered statistically significant. FDR, False discovery rate.

1575 Intensified Enveloped Vector Production Using Continuous Perfusion Bioprocessing

Lynn Svay, Hu Zhang, Robert G. Johnson

GenVivo, San Marino, CA

Background A great demand of vectors for gene therapy and vaccination drives development of disruptive technologies for vector production beyond established technologies for non-enveloped gene transfer vectors such as AAV. New modalities in the cell and gene therapy industry also require innovation in process technologies and manufacturing methods to keep pace. We address this need by evaluating tangential flow depth filtration (TFDF) technology for the perfusion process to produce enveloped vectors from a human-derived cell line in single use 3L bioreactors. Although alternative tangential flow (ATF) and tangential flow filtration (TFF) have been applied to the perfusion process for producing monoclonal antibodies due to their large membrane surface, ease to implementation, high recovery of viable cells, and a small footprint, fouling of the surface of ATF and TFF fibers associated with the build-up of cells, cell debris, particulates and the extracellular secretive products are one of the challenging issues for a long perfusion process. TFDF uses a depth filter with a micro-meter pore size in a tangential flow mode, realizing a high efficiency in cell retention and circumventing the fouling issue. **Methods and Results** The human-derived suspension cells were expanded in shake flasks prior to inoculation into 3L single use bioreactors. The inoculation density was in the range of 1-5 x 10^6 cells/mL. The bioreactors were

controlled via BIOSTAT-DCU II at a power per unit volume of 10-30 W/m3, a temperature of 37°C, a pH set point of 7.0 and a dissolved oxygen concentration of 40%. TFDF filters (30 cm^2) at a pore size of 3-5 micron were used for the perfusion process, and the shear rate cross the filter surface was kept at 2000 s-1. Various permeate flow rates in the range of 0.5- 5.0 VVDs (volume per vessel volume per day) were applied. The viable cell density of 50- 60 x 10^6 cells/mL was achieved after employing a cell specific perfusion rate (CSPR) in the range of 40-60 pL/cell/day and manual or continuous cell bleed, and the cell viability was greater than 80% after more than 10 days of perfusion. The physical and infectious titers of the vectors produced in the reactors were very similar to those in the permeate, thus suggesting that the sieving efficiency of the TFDF filters for these enveloped vectors was around 100%. The TFDF filter allowed us to maintain the production culture up to 10 days without filter fouling, and we could continue to collect the vectors produced each day, enabling 10-20 fold greater total vector production. **Conclusion** Our study demonstrates the feasibility of applying TFDF filters in the perfusion process for the production of an enveloped gene transfer vector. The TFDF technology could have a great potential in the perfusion process for producing various therapeutic products from mammalian cells.

1576 HLCN061: An "Off-the-Shelf" Gene Engineered Human iPSC-Derived NK Cell Product for the Treatment of Solid Tumors

Hironobu Kimura, Yuma Fukutani, Norihiro Tsuneyoshi, Kodai Saito, Makoto Hayashi, Yosuke Yamazaki, Yusuke Torisawa, Tetsuya Sakurai, Sono Watanabe, Kotoko Miyata, Yuka Sato, Kumiko Goto, Yoichi Naritomi, Tohru Ozaki, Masashi Yamada, Kenji Kurachi, Tomonori Hosoya, Yuriko Takeno, Fusako Nishigaki, Kouichi Tamura

HEALIOS K.K., Kobe, Hyogo, Japan

NK cells are a member of innate immunity and contribute on elimination of virus-infected cells, stressed cells, and tumor cells. Different from T cells, NK cells do not need to be sensitized before target and do not cause GVHD in the allogenic setting. Thus, NK cells are thought to be a good candidate of off-the-shelf products for adoptive cell therapy. Currently, peripheral blood or cord blood has been used for the major source of NK cells for immunotherapy. However, these NK cells are heterogenous, and the efficacy of these cells is donor dependent. While iPSC-derived NK cells are easy to control their quality by standardizing the starting material. Moreover, iPSC has an advantage in gene modification to generate a desired cell. We developed HLCN061, NK cells derived from genetically engineered human iPSC (hiPSC), expressing molecules that enhance the anti-tumor activity, homing to tumor and persistence for the treatment of solid tumors. *NKG2D*, high affinity *CD16*, *CCL19*, *CCR2B* and *IL-15* genes under the control of the human *EF1a* promoter were introduced into hiPSCs by using PiggyBac transposase system. Then we selected a genetically engineered hiPSC clone 18H5 by expression of transgenes and NK lineage differentiation capacity. The clone 18H5 showed a normal karyotype, and insertion of exogeneous genes shows minimum effect on expression of endogenous genes nearby insertion sites of integrated genes. Furthermore, we developed a robust manufacturing protocol for differentiating hiPSCs to NK cells using an automated perfusion feeder-free culturing system. Our system can manufacture 5x10^{10} cells of HLCN061 from 1x10^5 cells of clone 18H5 by using a 3-liter bioreactor. HLCN061 showed robust anti-tumor activity against various cell lines derived from solid tumors. Interestingly, primary NK cells showed a reduction of cytotoxicity against IFN-γ-treated tumor cells, while HLCN061 showed higher cytotoxicity against them. HLCN061 was able to migrate to the inside of tumor spheroids dependent on its CCR2B expression. Forced expression of IL-15 enhanced the persistence of HLCN061 in immunodeficient mice without the support of human cytokines. Intravenously injected HLCN061 was still detected in the lung at 39 weeks after injection without tumorigenesis. Finally, HLCN061 did not show any cytotoxicity against normal human PBMC. Thus, these in vitro and in vivo proof-of-concept studies promise that HLCN061 might be a good adoptive cell therapy product for the treatment of solid tumors.

1578 Rare Disease Patient Advocacy Perspectives on the Promise and Challenges of Gene Therapy

Kristin Voorhees[1], Kim McCleary[2], Kenneth Hobby[3], Marcus Landgren[4], Iris Ferrecchia[5], Kirsty Hoyle[6], Juana I. Navarrete[7], Amanda Jaksha[8], Kristin Smith[1], Rupal N. Gupta[1], Eric Crombez[1]

[1]Ultragenyx Pharmaceutical Inc, Novato, CA,[2]Kith Collective, Arlington, VA,[3]Cure SMA, Elk Grove Village, IL,[4]Scandinavian Association for Glycogen Storage Disease, Limham, Sweden,[5]Association for Glycogen Storage Disease, Waterloo, IA,[6]Metabolic Support UK, Clwyd, United Kingdom,[7]Universidad Nacional Autónoma de México and Asociación Mexicana de Genética Humana, Mexico City, Mexico,[8]International Foundation for CDKL5 Research, Wadsworth, OH

Background: Gene therapy is a rapidly evolving field that offers new hope while presenting unique challenges. It is vital to understand the questions, expectations, and fears of patient communities and to share learnings across diseases. This approach can help to ensure community perspectives are incorporated into the development of potential treatments. An advisory council was formed to meet with patient advocacy group (PAG) leaders to better understand a range of perspectives on gene therapy interest, knowledge, and acceptance and identify shared goals in developing and providing gene therapy information. **Methods:** Four hybrid meetings were held with 9 PAG representatives in five countries across a range of rare diseases. Meetings also included a moderator and biotechnology employees. Meetings lasted 11 hours over 4 months. Pre-meeting surveys were conducted, containing open-ended and discrete questions to help lead discussion. Discussions were recorded to aid in meeting summarization. **Results:** In general, the communities represented were curious and enthusiastic about gene therapy, though the same factors driving acceptance were also factors behind hesitancy. Information and education gaps can lead some community members to underestimate risks and overestimate benefits associated with gene therapy, and others to avoid gene therapy all together. Gene therapy is sometimes seen as a "cure" and a "silver bullet," with enthusiasm often motivated by a desire to have lasting relief from daily management of conditions and experience a sense of predictability, normalcy, and freedom. Simultaneously, lack of knowledge and uncertainty of the extent and durability of benefit

lead others to view gene therapy as an unacceptable risk. Clear and plain-language education on basic gene therapy facts can help promote understanding and demystify the topic and current research. Managing expectations and clearly communicating benefits and risks of gene therapy are critical and require different approaches at each stage of development and commercialization. Healthcare professionals are trusted partners in gene therapy decision making; however, not all patients have access to knowledgeable specialists. Patients treated with gene therapy also have a strong influence and can help address myths and misinformation by sharing their lived experiences, especially in rare disease. PAG leaders expect biopharma companies studying gene therapy to partner with communities to provide transparent information and help manage expectations at all stages. **Conclusions:** Bringing together diverse PAGs and gene therapy specialists identified core themes that need to be addressed to support gene therapy decision making in communities where it is being actively studied. These include 1) supporting growth and building capacity of PAGs and 2) developing different education approaches to manage expectations and demystify gene therapy in general and for specific disease states. Biopharma companies, healthcare professionals, advocates, and patients have critical roles to play in providing information. Additional research should explore how information-seeking practices of patient communities may shape the understanding of and interest in gene therapy.

1579 Generation and Evaluation of rAAV Vector for the Treatment of COX20 Deficiency

Peiyi Guo[1], TramAnh M. Nguyen[1], Guangping Gao[1,2], Dominic J. Gessler[1,2]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Co-corresponding author, Worcester, MA

Cytochrome c oxidase 20 (COX20) is a ubiquitously expressed protein. It plays vital roles in assembling mitochondrial complex IV by stabilizing its COX2 subunit on the mitochondrial inner membrane as a chaperone protein. Loss of COX20 leads to reduced protein level and enzyme activity of complex IV. COX20 deficiency is a rare, autosomal recessive disease, although increased cases have been reported in the last few years. Patients with COX20 deficiency develop early onset hypotonia, ataxia, areflexia, dystonia, dysarthria, and sensory neuronopathy but without severe cognitive or intellectual disabilities, suggesting defects in the peripheral nervous system and a primary degeneration of sensory neurons in the dorsal root ganglia. Unfortunately, the current treatment of COX20 deficiency is limited to supportive care, and effective therapy is still unavailable. In this study, we developed recombinant adeno-associated virus (rAAV)-based gene therapy vectors for the treatment of COX20 deficiency. Two isoforms of COX20 (201 and 203) exist, but their therapeutic implications are unknown. To differentiate between endogenous and exogenous COX20, we designed six vectors with either isoform and with or without FLAG-tagged to the c- or t-terminus driven by the chicken beta-actin (CB) promoter. Protein expression analysis confirmed that protein levels were equivalent for COX20 with or without FLAG tag. The mitochondrial localization of COX20 is essential for its function. Therefore, we first evaluated the different constructs' ability to express COX20 that localizes to mitochondria. Using a co-localization assay, we found that COX20 expressed from each construct localizes to mitochondria. Subsequently, all constructs were packaged into rAAV9 to evaluate their function and possible toxicity in mice via systemic delivery. In summary, this early proof-of-concept study holds promise for the development of gene therapy for COX20 deficiency.

1580 Development of Adeno-Associated Virus Producer Cell Lines by Small Molecule Inducible Expression of Packaging Genes

Nicholas Dietrich, Samantha Lasater, Joseph Rabinowitz, Jennifer Israel

Kriya Therapeutics, Inc, Research Triangle Park, NC

A major challenge in the use of recombinant adeno-associated viruses (rAAVs) for gene therapy is the requirement for large scale production of the viral particles. A traditional method for vector production is the triple transfection method, where packaging (Rep and Cap), adenovirus helper genes, and transgene elements on separate plasmids are transiently expressed in production cell lines such as HEK293T. A major limitation of this method is the requirement that each cell receives all three plasmids to produce rAAV, reducing the potential efficiency of viral production. One strategy to overcome this limitation is the generation of production cell lines that stably express one or more of the packaging genes and thereby reduce the number of plasmids delivered by transient transfection. However, constitutive expression of Rep is toxic in many cell lines, limiting the utility of this approach. To overcome this limitation and generate producer cell lines that do not require the triple transfection mechanism, we designed a Rep expression construct that expresses Rep protein only upon treatment with a small molecule. Here, we demonstrate that transient transfection of this construct and the other packaging components allows for inducible Rep expression and results in packaging of rAAV following small molecule administration. We then generated stable cell lines that express this construct and demonstrated Rep inducibility and AAV packaging. These cells will provide the opportunity for increased vector production efficiency, and potentially decrease production costs and increase scalability.

1581 Development of Allogeneic HSC-Engineered iNKT Cells for Off-the-Shelf Cancer Immunotherapy

Yanruide Li

University of California, Los Angeles, Los Angeles, CA

Cell-based immunotherapy has become the new-generation cancer medicine, and "off-the-shelf" cell products that can be manufactured at large scale and distributed readily to treat patients are necessary. Invariant natural killer T (iNKT) cells are ideal cell carriers for developing allogeneic cell therapy because they are powerful immune cells targeting cancers without graft-versus-host disease (GvHD) risk. However, healthy donor blood contains extremely low numbers of endogenous iNKT cells. Here, by combining hematopoietic stem cell (HSC) gene engineering and in vitro differentiation, we generate human allogeneic HSC-engineered iNKT (AlloHSC-iNKT) cells at high yield and purity; these cells closely resemble endogenous iNKT cells, effectively target tumor cells using multiple mechanisms, and exhibit high safety and low immunogenicity. These cells can be further engineered with chimeric antigen receptor (CAR) to enhance tumor

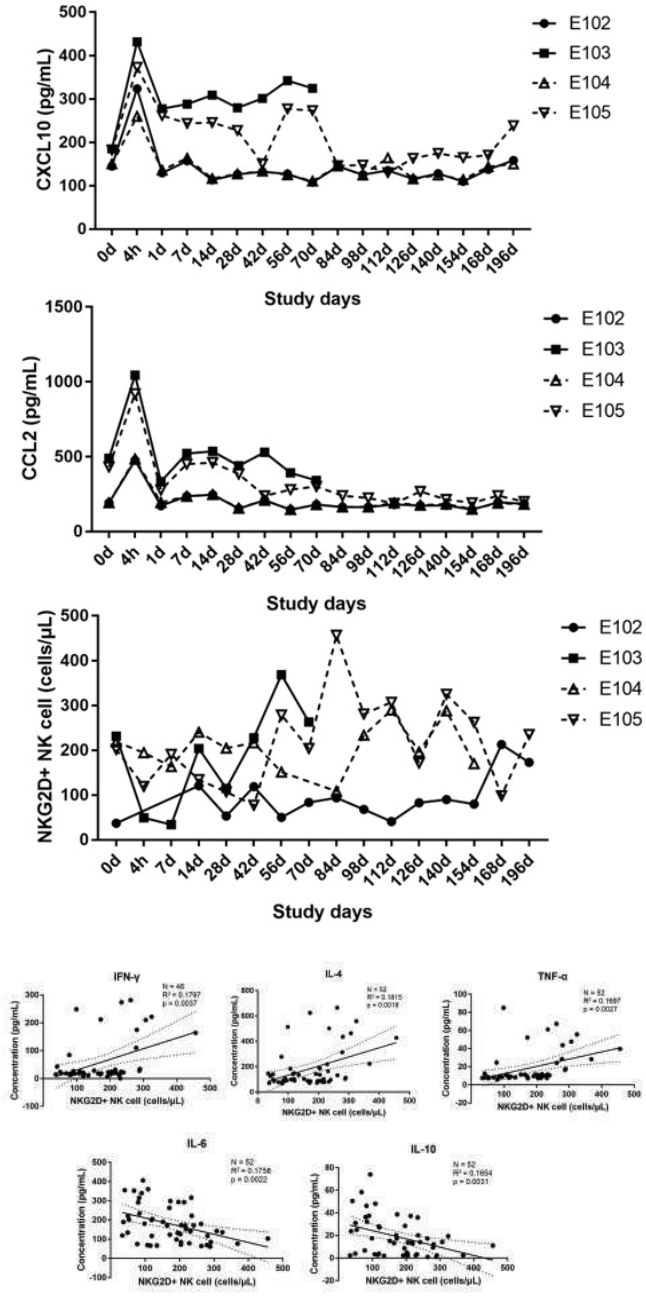
targeting or/and gene edited to ablate surface human leukocyte antigen (HLA) molecules and further reduce immunogenicity. Collectively, these preclinical studies demonstrate the feasibility and cancer therapy potential of AlloHSC-iNKT cell products and lay a foundation for their translational and clinical development.

1582 Exploration of Immune Cell and Cytokine Biomarkers after Multiple Administrations of Autologous Natural Killer Cells in Patients with Solid Tumor

Wonsuk Shin[1], Hee Jung An[2], Chan Kim[3], Young Seok Baek[4], Hyounggyoon Yoo[1], Yil-Seob Lee[1], Anhye Kim[1]

[1]Department of Clinical Pharmacology and Therapeutics/Global Clinical Trial Center, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Korea, Republic of,[2]Department of Pathology / CHA Future Medicine Research Institute, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Korea, Republic of,[3]Medical Oncology, Department of Internal Medicine, CHA Bundang Medical Center, CHA University School of Medicine, Seongnam, Korea, Republic of,[4]Immunotherapy Team, New Biological Entity (NBE) Research, R&D Division, CHA Biotech, Seongnam, Korea, Republic of

Natural killer (NK) cells have been studied widely due to its immunotherapeutic potential for various indications. To develop NK cell therapy for clinical implications successfully, the basic data should ground to establish the standard regimen based on biomarkers to monitor safety and exposure-response relationship. From these perspectives, the most of previously reported studies have limitations such as partial or short-term observation of biomarkers, resulting in difficulties of comprehensive interpretation. Thus, we aimed to explore the biomarkers including various types of immune cells (NK cell, T cells, and myeloid-derived suppressor cells) and cytokines (tumor suppressor and protumoral cytokines) and their relationships after multiple administration of CBT101 (autologous NK cells) in patients who underwent curative surgery and adjuvant therapy for solid cancer. The patients received the CBT101 intravenously 13 times every 2-weeks. Whole blood samples for cell and cytokine biomarkers were obtained up to 4 hours after the first administration and before each subsequent administration. Four patients were enrolled and three patients completed the study. The cytokines including CXCL10 and CCL2 increased at 4 hours after first administration. The trough values of NKG2D$^+$ NK cell counts measured before each administration showed steady increase until 5-6 administrations. NKG2D$^+$ NK cell counts presented positive correlations with tumor suppressor cytokines such as IFN-γ, TNF-α, and IL-4 and negative correlations with tumor growth cytokines such as IL-10 and IL-6. The findings of this study suggested the needs for reference values of the biomarkers and for further studies with larger sample size to understand of mechanism of action of NK cells and to form the basis for clinical implications.



ACKNOWLEDGEMENT: This human-deprived material research was conducted in the patients participating in the phase 1 clinical trial of CBT101 sponsored by CHA Biotech Co., Ltd., Seongnam, Republic of Korea (NCT04557306). This research was supported by a grant from the Korea Health Technology R&D Project through the Korea Health Industry Development Institute (KHIDI), funded by the Ministry of Health & Welfare, Republic of Korea (grant number: HI19C0790, HI16C1559). The authors declare no conflict of interests to disclose.

1584 Upregulation of AEG-1 Expression Attenuates Granule Cell Dispersion and Seizure Development by Suppressing mTORC1 Activation in KA-Induced TLE Mice

Sehwan Kim[1], Youngpyo Nam[2], Hanwoong Woo[2], Sang Ryong Kim[1]

[1]School of Life Sciences, Kyungpook National University, Daegu, Korea, Republic of,[2]Brain Science and Engineering Institute, Kyungpook National University, Daegu, Korea, Republic of

Although granule cell dispersion (GCD) in the hippocampus is known to be an important feature associated with epileptic seizures in temporal lobe epilepsy (TLE), the endogenous molecules that regulate GCD remain elusive. Here, we have identified that the expression of AEG-1 is upregulated in the DG of a KA-induced mouse model of TLE. We further demonstrated that AEG-1 upregulation by AAV1 delivery in the DG induced anticonvulsant activities such as the delay of seizure onset and inhibition of spontaneous recurrent seizures (SRS) through GCD suppression in the mouse model of TLE, while the inhibition of AEG-1 expression increased susceptibility to seizures. The present observations suggest that AEG-1 is a novel regulator of GCD formation and seizure development associated with TLE, and the induction of AEG-1 in the DG may have a therapeutic potential against epilepsy.

1585 Immunodeficient Mouse Models to Assess Human HSPC Engraftment and Gene Editing: NSG vs. NBSGW

Zulema Romero Garcia, Beatriz Campo, Xiaomeng Wu, Donald B. Kohn

Department of Microbiology, Immunology and Molecular Genetics, UCLA, Los Angeles, CA

Humanized mouse models are an essential tool in the field of gene therapy to assess long-term engraftment of human hematopoietic stem and progenitor cells (HSPC) and persistence of their genome editing. In the NSG (NOD-Prkdc^{scid}, IL2rg^{null}) strain, the combination of the NOD, SCID (DNA-PK) and IL2rg mutations results in an ablation of adaptative immunity, severe deficiency of innate immunity and a high receptivity to the engraftment of human HSPC after cytoreductive irradiation. Introduction of the viable c-kit mutant gene (Kit$^{W41/W41}$) into the NSG strain resulted in a new mouse model (NBSGW) in which transplanted human HSPC have a competitive engraftment advantage, yielding enduring engraftment without irradiation. We hypothesize that the facilitated engraftment of human HSPC due to the genetic disadvantage of host NBSGW mice may allow the engraftment of more mature, less primitive CD34+ progenitor cells, diminishing the ability to distinguish adverse effects of *ex vivo* manipulation on long-term primitive HSPC engraftment potential. The consequences of this are that the toxicity derived from gene editing protocols might be underestimated, while hematopoietic stem cell potential and long-term maintenance of genome-editing might be overestimated. To test this hypothesis, NSG and NBSGW mice were transplanted from the same pool of mobilized peripheral blood HSPC edited using CRISPR/Cas9 to correct the *HBB* sickle mutation by a single stranded deoxyoligonucleotide donor. Both mouse models received the same number of cells, and while the NSG mice (n=12) had sub-myeloablative irradiation (250 rad), the NBSGW mice (n=13) did not. Four months after transplant, mice were euthanized and human cell engraftment and *HBB* gene correction were assessed in the bone marrow (BM) and spleen of the mice. No deaths occurred in the NSG group from the conditioning irradiation. Human CD45+ cell engraftment was about 1.5-times higher in BM and spleens from the NBSGW mice than in the NSG mice. The same hematopoietic cell lineage distributions were observed in BM and spleen in both mouse models. Gene correction by homologous directed repair (HDR) and non-homology end joining (NHEJ) were significantly higher in the NBSGW (HDR- 22±2.7%, NHEJ- 52.5±4%) than in the NSG mice (HDR- 18.4±1.1%, NHEJ- 56.7±2.4%) in BM, but no differences were found in spleens. Human CD34+ cells and murine CD45+/lineage-negative cells were sorted from the BM from 6 mice from each group. Single cell-RNA-sequencing (sc-RNA-Seq) is ongoing to characterize any transcriptional differences in the human HSPC engrafted in each mouse model, as well as to investigate the phenotype of the murine HSPC from each model. Secondary transplants were performed with BM from 5 NBSGW and 5 NSG primary recipients transplanted into equal numbers of both NBSGW and NSG secondary recipients. No significant differences were observed between the two mouse models in either secondary engraftment of human CD45+ cells (ranging from zero to 2%) or gene editing (with marking detected in all the engrafted mice but one mouse). We conclude that the NBSGW mice may allow persistence of more committed and proliferative progenitor cells, resulting in significantly greater percentages of human cells. NBSGW xenografts may show higher HDR frequencies because the committed progenitors are less quiescence and more able to correct by HDR the double strand breaks produced by Cas9 nuclease, compared to the more quiescent less committed HSPC. As such, the NSG model may provide a more stringent assessment of long-term engrafting HSPC and HDR frequency. It is important to be understand differences in model systems to use them to most accurately predict outcomes of clinical gene therapy.

1586 Achieving Uniformity in Transduction with AAV Gene Therapy to Muscular Dystrophy

Qi Lu[1], Pei Lu[1], Marcela P. Cataldi[2], Molly Holbrook[3]

[1]McColl Lockwood Laboratory, Atrium Health, Charlotte, NC,[2]McColl Lockwood Laboratory, Atrium Health, Harrisburg, NC,[3]Atrium Health, Charlotte, NC

AAV-mediated gene replacement therapy is currently the most promising treatment for muscular dystrophies (MD). Recent clinical trials have shown the potential of the therapy to delay and even cure the diseases. However, multiple side effects, including renal toxicity, liver damage up to fatalities have been reported by ongoing clinical trials. Importantly, severe incidences are clearly dose-related, with fatalities largely linked to AAV dosage above 1e14 vg/kg body weight. Therefore, achieving efficacy with lower AAV dose is critical for AAV gene therapy to MD as discussed recently by Cellular, Tissue, and Gene Therapies Advisory Committee (2021). Toxicity in clinical applications is convoluted with another concern, the heterogeneity of transgene expression when the dose of AAV is lower than the potential lethal doses. Preclinical animal model tests and reports from clinical trials with doses lower than 1E14 vg/kg induce variable transgene expression between muscles and among fibers of individual muscle including heart

and diaphragm. There is little doubt that the fibers lacking transgene expression will continue to degenerate and transgene overexpression could also be detrimental. AAV gene therapy therefore faces a dilemma of either using super high doses of currently available AAV serotypes and vector systems to achieve desirable efficacy with high risk of severe side effects, or opting to limit AAV dosage for safety, but achieving suboptimal and probably shorter-term efficacy. Two main approaches can be used to dissolve the dilemma. One is to explore new and more potent AAV strains with higher tropism to skeletal and cardiac muscles. Several recent reports have shown propitious progress with the development of MyoAAVs and AAV.cc47 which showed superior efficiency and selectivity to transduce muscles in mice and non-human primates. However, these synthetic strains of AAV produce the same variable distribution (mosaic) pattern in muscles, containing fibers with transgene expression ranging from higher than normal to undetectable within individual skeletal and cardiac muscles. While viral tropism plays role for variable expression, differential activation of promoters by different muscles and fiber types is also a critical factor. Therefore, one alternative solution to minimize heterogeneity is promoter modulation. This has been extensively studied in the early stage of AAV gene therapy to muscular dystrophy, but with focus on increasing efficiency rather than distribution in transduction. All promoters currently in use produce highly variable expression. In this study, we have constructed several synthetic regulatory cassettes based on muscle specific MCK promoter/enhancer components in combination with other essential regulatory elements with the aim to improve transduction efficiency and especially distribution in cardiac and skeletal muscles. The expression vectors with the cassettes were packed by AAV9 and the virus was delivered systemically in a FKRP mutant mouse models with P448L mutation. The mice experience progressive dystrophic phenotype with extensive muscle degeneration and shortened life span. One of the regulatory cassettes MCKopt5 produces higher levels of transduction in both cardiac and skeletal muscles than CK7 driven vector. More importantly, FKRP expression restored matriglycan expression homogeneously in both types of muscles when only 4e12vg/kg was administrated whereas CK7 based promoter requires 5e13vg/kg to achieve expression in near 100% muscle fibers of skeletal muscles. This pattern of transduction is highly desirable for achieving long-term efficacy with low AAV dosage, avoiding dose-related toxicity. A combination of the synthetic regulatory cassette with high muscle tropism AAV serotype constitute ideal AAV gene therapy to muscular dystrophy.

1587 Exploiting a Novel Gene Regulatory Code for Retinal Gene Therapy

Rosa Maritato, Emanuela D'Andretta, Enrico Maria Surace

Department of Translational Medical Sciences (DiSMeT), Univesity of Naples "Federico II", Napoli, Italy

Rhodopsin-Autosomal dominant Retinitis Pigmentosa (RHO-ADRP) is a progressive photoreceptor degeneration leading to an incurable loss of vision. To treat this blinding inherited disease, we established a solid gene therapy proof of principle with Adeno-associated virus (AAV) vectors, which couples two approaches, gene silencing with gene replacement. Silencing and replacement approach was generated by inserting in a single AAV vector two expression cassettes carrying independent promoter elements of differential strength as drivers for the silencer and the replacement components. The silencing step is achieved through an unconventional transcriptional repression system, in which an exclusive use of DNA-binding domain (DBD) (ZF) operates without the aid of repressor domains. We demonstrated that the sole binding of this ZF-DBD (ZF6) to a short and accessible (unbound from endogenous transcriptional modulators) DNA Cis Regulatory Elements (CREs) blocks RHO expression, at low doses with both limited off targeting and engagement of cellular systems. Based on this result, we further explored these CREs with higher resolution by changing the number, orientation, order, spacing and their sequence composition demonstrating a wide range of modulation of the transcriptional outputs. By exploiting the gene regulatory code found, we obtained a reciprocally controlled transgenes expression of silencing and replacement which also operates in a wide range of vector doses. Hence, a safer and more efficacious gene therapy of RHO-ADRP is demonstrated.

1588 A Novel Next-Gen Sequencing Library Preparation Method to Sequence Small, Long, and Low-Quality (Fragmented/Degraded) RNA with Low (*Pico*-Grams) Quantity of Templates for Better Diagnostics, Biomarker Discovery, and Research

Praveensingh B. Hajeri, Masato Yamamoto, Subbaya Subramanian, Nuri Alpey Temizz

Department of Srugery, University of Minnesota, Minneapolis, MN

Background and limitations of current technologies*:** Next-generation sequencing (NGS) of RNA and DNA is a method of high-throughput sequencing of biological samples. There are several well-established methods in published literature and also commercially available in the form of products/kits dedicated to sequencing total RNA, DNA, exome, small RNAs, and selected panels of gene/ loci to address specific issues.However, it has been a great challenge to sequence highly fragmented and degraded DNA/RNA due to the limitations of library preparation methods. This affects the sequencing of clinical samples, biological research materials, liquid biopsy, FFPE tissue, exosomes, forensics, cell-free RNA/DNA, and archeology, among several other types of materials. A large fraction of archived and even fresh samples do not generate high-quality data, which cripples basic research, biomarker discovery, and diagnostics. Currently, it is also impossible to sequence small RNAs alone or small and long RNAs together with pico-gram quantities of total RNA template. ***Methods and results: We have addressed these limitations by developing a novel method to prepare NGS libraries from pico-gram quantities of total RNA templates. Our methods could efficiently capture RNA of all sizes (20bp and above, including small and long RNAs) simultaneously and detect 2-10 times more unique transcripts at a similar sequencing depth than the current state-of-the-art methods. We could capture 20,000 to 100,000 more transcripts than an established method in a proof-of-concept study. We could capture small (as small as 20 bases and above) and long RNAs in the same library using very low (pico-grams) quantities of total RNA. ***Applications and broader impacts:*** Our method is applicable to highly fragmented and degraded samples like biological samples,

clinical samples, FFPE tissue, cell-free RNA/DNA, liquid biopsies, archeological samples, and also normal samples. The variations and errors observed in NGS data due to differential degradation between samples are negligible in our method. This helps generate consistent and high-quality sequencing data. We could generate 2-10 times more high-quality data with as little as 500pg of total RNA, which is close to the total RNA obtained by a single cell and hence applies to single-cell sequencing. The method is compatible with automation as well. Due to its high efficiency and sensitivity, we think our method will enable better diagnostics, biomarker discovery, and research.

1589 Deep Characterization of Allogeneic PBMC Donor Starting Materials to Assure Better Quality Cell Immunotherapies

Robert J. Tressler

Research and Development, Excellos, San Diego, CA

The increased focus on the development of allogeneic cell immunotherapies for the treatment of cancer has highlighted the need for deeper characterization of donor starting materials, in particular PBMCs that may serve as source material for various adoptive immunotherapy approaches. We report on our efforts in this aspect by evaluation of healthy donor immune cell repertoires by FACs, including CD3, CD4, CD8, CD14, CD19, CD45 and CD56 cell subsets present in leukapheresis samples collected from donors ranging in age from 18 to 70 years. Additionally, we have characterized PBMC, CD3, CD4 and CD8 cell subsets for functional aspects that are key aspects of potency and durability of response in cancer indications. These include their effector function potential using a proteomics-based assay platform, metabolic fitness as reflected in glycolytic rates, and standard cytokine release and cell killing assays. To date the results indicate significant donor variability in all the parameters evaluated and a clear correlation to donor age in terms of effector function, metabolic state, and specific immune cell subset levels. These data indicate that deeper donor starting material characterizations may facilitate better cell immunotherapies in terms of potency and effectiveness for the treatment of oncology indications.

1590 An Electroporation Platform for Enhanced Non-Viral Genome Editing with Cutting-Edge Buffer for Optimal Homology-Direct Repair

Shahan Molla[1], Janhavi Choudhari[1], Wei Han[2], Kevin Liaw[2], Kelvin Chen[2], Omar Sheriff[2], Narae Ahn[1], Deepak Kumar[1], Nektaria Andronikou[1], Namritha Ravinder[1], Arseny Smirnov[1]

[1]ThermoFisher Scientific, Carlsbad, CA,[2]ThermoFisher Scientific, Singapore, Singapore

Transfection of cells by introducing foreign nucleic acids or proteins to alter their genotype or phenotype is crucial in a variety of life science applications. A wide range of transfection methods exists and choosing which approach to use often depends on its suitability to the application in question. Electroporation is a physical transfection strategy that uses an electrical pulse to create temporary pores in cell membranes through which genetic materials can pass into cells. It is a highly efficient and powerful tool that has been shown to have superior performance with gene editing-based payloads, such as CRISPR and TALEN. The Invitrogen Neon Transfection System, a widely used research-focused electroporation instrument, has been shown to be a reliable electroporation tool. It utilizes a pipette tip chamber to generate a uniform electric field for a significant increase in transfection efficiency and cell viability. Neon NxT Electroporation System is an improved electroporation instrument inspired by the Neon System and maintains the "tip" electroporation design. It leverages key competitive advantages secured by the Neon. We have observed a consistent equivalent or better performance of the Neon NxT Electroporation System when compared to its legacy product Neon Transfection System using a wide variety of mammalian cells and payloads. We have observed 80 to 90% transfection efficiency for GFP plasmid DNA in HeLa, BC-1, Jurkat, and HEK293 using both 10 µl and 100 µl reaction tips of the Neon NxT Electroporation System. For eGFP mRNA, we observed more than 90% transfection efficiency in Jurkat, HEK293, and Primary Naïve T cells. In terms of CRISPR/Cas9 regulated HDR-driven non-viral genome editing, we have observed 40-70% knock-in efficiency in Jurkat, K562, and primary activated T cells. We have observed more than 90% CRISPR/Cas9 regulated knock-out efficiency in primary activated T cells and hematopoietic stem cells (HSCs). In addition, we have observed more than 50% CRISPR/Cas9 regulated knock-out efficiency in primary natural killer (NK) cells using Neon NxT Electroporation System. Electroporation of these cells had minimal effect on cellular viability. In Addition, the Neon NxT Electroporation System introduces Resuspension Genome Editing Buffer. The Neon NxT Electroporation System in conjunction with Resuspension Genome Editing Buffer is a powerful tool used to increase knock-in efficiency in mammalian cells through CRISPR/Cas9 genome editing. It was designed to drive the rate of homology-directed repair (HDR) in cells. The system has been demonstrated to significantly increase knock-in efficiency in three different mammalian cell types, with an approximately 5-fold increase in Jurkat cells, a 2-3.7-fold increase in K562, and activated primary T cells, respectively. The system also improved knockout/cleavage efficiency in hematopoietic stem cells (HSCs) and natural killer cells (NKs). Overall, the Neon NxT system provides broad utility in CRISPR/Cas9 applications by improving HDR-derived knock-in efficiency in a range of mammalian cells.

1591 The Need for Speed: Maximising Adeno-Associated Virus (AAV) Vector Productivity with High Throughput (HTP) Platforms

Helene Trottin

Pharmaron, Liverpool, United Kingdom

Pharmaron has established a multi-faceted purification toolbox approach using small scale upstream processing (USP) and downstream processing (DSP) HTP systems, to deliver rapid process optimisation and manufacture of a wide range of Adeno-Associated Virus (AAV) serotypes and products. With utilisation of Ambr15 and Ambr250 bioreactor systems, Pharmaron can provide an initial small-scale assessment of a product's performance in their platform process at a fraction of the cost, space and resource of a full lab scale study. Equally the use of an automated liquid handling robot in DSP, allows Pharmaron to conduct an early assessment of purification for a gene therapy product. They can then concentrate on a targeted HTP screening approach utilising DoE to assess, for example, varying

seeding densities and transfection conditions in USP, to varying chromatography buffers and resins in DSP. This targeted approach drastically reduces chemistry, manufacturing and controls (CMC) development timelines, maximises productivity and drives results. Despite this, the use of HTP and automated processes can cause bottlenecks in an end-to-end platform which delivers gold standard analytics as an end point; therefore, Pharmaron has developed a number of HTP analytical methods to match this output. Through integration of size exclusion (SEC) and anion exchange (AEX) ultra-performance liquid chromatography (UPLC) systems for fast titre generation and Empty:Eull capsid quantification, Pharmaron has developed a testing strategy for rapid screening of hundreds of samples in a 24-hour period. Here they show that high throughput platforms provide advanced technical solutions which drive reproducibility, productivity and reduced process times.

1592 Azide-Functionalized SpCas9 Enables Regioselective Conjugation of Auxiliary Therapeutic Molecules Such as Functional siRNA

Danny Wilbie[1], Matt Timmers[1,2], Asimina Kogkalidou[1], Erik R. Hebels[1,2], Tina Vermonden[1], Enrico Mastrobattista[1]

[1]Pharmaceutics, Utrecht University, Utrecht, Netherlands,[2]Cristal Therapeutics, Maastricht, Netherlands

CRISPR gene therapy is reaching adolescence, as the first landmark clinical trials are underway. Current *in vivo* gene editing focusses on functional gene knock-out, in which the Cas9 protein is used to create double stranded DNA breaks. Following this, DNA repair by non-homologous end-joining induces frameshift mutations, knocking out the gene. Other CRISPR apoplications such as faithful gene correction are still an actively developing field. Progress towards improving gene correction was made by engineering the SpCas9 protein to exploit novel gene correction modalities. Most examples are fusion proteins, such as base-editors and prime-editors. The design space for SpCas9 protein fusion is however limited to the C-terminus due to the presence of active sites near the N-terminus. This limitation prompted the current study, in which we aimed to develop azide-functionalized SpCas9 for click-chemistry to the protein surface. The main aim was retaining protein activity following conjugation of functional molecules to SpCas9.First we identified regions on the protein surface in which SpCas9 can be modified without loss of activity, based on earlier literature. We chose to substitute exposed aromatic amino acids in these regions based on the SpCas9 crystal structure (PDB: 4cmp) with p-azido-phenylalanine (pAzF) as click-chemistry handle. pAzF was introduced by recombinant expression in *E.coli* co-expressing pEVOL-pAzF (Addgene #31186) for amber STOP codon reprogramming. After purification we characterized four candidate pAzF-SpCas9 constructs on their bioactivity, purity and conjugation capabilities to Alexa Fluor 647 (AF647)-DBCO. One variant in particular, 539pAzF-SpCas9, retained bioactivity after conjugation. We applied this 539pAzf-SpCas9 platform for co-delivery of SpCas9 RNP complexes and siRNA as model for synergistic therapy. We functionalized siRNA with a releasable linker containing TMTHSI for copper-free click conjugation to the SpCas9 protein. The linker releases its cargo in reducing environments such as the cytosol. This results in release of unmodified siRNA and SpCas9 with a small chemical side group on the azide. In a proof of concept study we show that SpCas9-siRNA complexes are generated with a 50-90% conjugation efficiency after two hours based on gel electrophoresis and densitometry. The conjugation is furthermore reversed in presence of 5 mM glutathione. Furthermore we show that in model cell lines for Cas9 and luciferase siRNA activity (HEK293t expressing eGFP or dual luciferase, respectively) both components are active after lipid nanoparticle delivery. Finally we show that co-encapsulation and co-delivery is improved by conjugation, based on differential fluorescent labeling (AF647SpCas9-AzF and rhodamine 3b-siRNA). We conclude that SpCas9 and additional therapeutic molecules is possible by regioselective conjugation, without significant activity loss of either cargo molecule. We intend to follow up with biologically relevant siRNA to improve CRIPSR gene correction using the homology-directed repair pathway.

1593 Can PK/PD Modeling and Simulation Bring a Gene Therapy (for β-thalassemia) to Patients-in-Need Faster?

Chris A. Learn

Cell and Gene Therapy Center of Excellence, Parexel, Raleigh, NC

Introduction: β-thalassemia is a rare hereditary genetic blood disease caused by mutations in the β-globin gene, resulting in reduced or absent production of functional hemoglobin. The standard care for patients with TDT requires regular (lifelong) transfusions of packed red blood cells. Previously, the only potential curative option in patients with transfusion dependent β-thalassemia (TDT) was allogenic hematopoietic stem cell (HSC) transplantation. Recently the FDA approved an autologous transplant/ex-vivo gene therapy beti-cel (betibeglogene autotemcel; commercial brand name: Zynteglo®), beti-cel is a gene therapy designed to add functional copies of a modified β-globin gene into TDT patients own HSC's. beti-cel consists of autologous CD34+ cells containing HSCs transduced with lentiviral vector encoding the $\beta^{A\text{-}T87Q}$-globin gene and produces hemoglobin containing $\beta^{A\text{-}T87Q}$-globin (HbA^{T87Q}). Peripheral blood vector copy number (PB VCN, expressed as average number of vector copies per diploid genome; c/dg) is a measure of drug product (DP) vector copies that is used to monitor transgene integration. Over the course of clinical development, the manufacturing process was optimized from DP process 1 to DP process 2 (the commercial DP process), specifically the transduction step to increase the percentage of vector-positive transduced cells (%DP LVV+ cells) and the total VCN. **Aims:** To develop a pharmacodynamic (PD) model to describe the PD profile of PB VCN and HbA^{T87Q} post beti-cel infusion. To identify and quantify both patient and DP specific factors that impacted PB VCN and HbA^{T87Q} time course as well as to determine the time required for both biomarkers to approach steady-state and thereby understand the dose-exposure-response relationship for beti-cel. **Methods:** As of 09Mar2021, data were available from 59 patients (n=39 non-β^0/β^0 genotype, n=20 β^0/β^0 genotype) enrolled in three clinical studies (HGB-204, HGB-207, HGB-212) and the long-term follow-up study (LTF-303). Patients were aged 4 - 35 years, weighed 16.3 - 95.4 kg, with 26 males and 33 females. A total of 18 patients received DP Process 1 and 41 patients received DP Process 2. A total of 566 PB VCN and

HbA^{T87Q} 560 observations were analyzed using a non-linear mixed effects modeling approach in NONMEM (Version 7.4, ICON, Hanover, MD). **Results:** DP manufacturing process and %DP LVV+ cells were identified as statistically significant covariates effecting the steady-state values and the time to approach steady-state for PB VCN and subsequently HBA^{T87Q}. Patients that received DP Process 1 compared to patients that received DP Process 2 were predicted to have a lower steady-state PB VCN (0.336 c/dg vs 1.5 c/dg) and HbA^{T87Q} (5.66 g/dL vs 8.85 g/dL) and a longer time to achieve 90% steady-state PB VCN (1.66 months vs 0.393 months) and HbA^{T87Q} (6.44 months vs 3.91 months). Age, weight, sex, race, or genotype did not impact PB VCN or HBA^{T87Q} time-course profiles. **Conclusions:** A one-time dose of beti-cel manufactured by DP Process 2, the commercial process, resulted in rapid increases in both PB VCN and HbA^{T87Q} (> 90% of steady-state values by 6 months) with durable responses observed out to the end of the follow up (up to 72 months). The non-linear mixed effects models developed were used to support the Biologics License Application (BLA) submission and may have facilitated the therapy being available to patients sooner.

1594 Designing Brain and Peripheral Tissue Regulatory Cassettes for rAAV-Based Canavan Disease Gene Therapy

Thomas Leland[1], Yue Zhang[1], Jiaming Wang[1], Tapan Sharma[1], Fang Zhang[1], Jackson McGowan[1], Anoushka Lotun[1], Jessica Epstein[1], Touraj Farzani[1], Eduardo Viscasillas-Reyes[1], Ran He[1], Qin Su[1], Jun Xie[1], Guangping Gao[1,2], Phillip WL Tai[1,2]

[1]UMass Chan Medical School, Worcester, MA,[2]Co-corresponding Authors, Worcester, MA

Canavan disease is a devastating autosomal recessive leukodystrophy that is caused by loss of function mutations in the aspartoacylase (*ASPA*) gene. The disease is usually lethal in the first few decades of life and has no approved treatments. Our lab has developed a recombinant adeno-associated virus (rAAV) vector-based gene therapy that shows efficacy in mice and is currently undergoing clinical trials. Like most approved rAAV-based gene therapies, the therapeutic *hAspa* transgene is driven by the ubiquitously active *CMV* enhancer/chicken β-actin (*CB*) promoter. The ideal gene therapy achieves transgene expression at therapeutic and/or physiological levels in the intended tissues, and negligible expression elsewhere. For rAAV-based gene therapies, transduced tissues are predominately defined by the tropism of the capsid and the activity of the promoter. Capsid engineering alone may not produce vectors that can confer the appropriate amounts of expressed transgenes across diverse tissues. Optimized regulatory cassettes must therefore be developed to direct transgene expression within the bounds of a capsid's tropism. We have identified a 3.4-kb sequence upstream of the mouse *Aspa* gene that we hypothesized to harbor distinct central nervous system (CNS) and peripheral tissue (PT) enhancers as demarcated by tissue-dependent epigenetic modifications. We predicted that these regions may be utilized in vector regulatory cassettes to enable tissue-specific transgene expression that mimics endogenous *Aspa* expression. We designed a series of luciferase reporter constructs containing the full *mAspa* promoter or combinations of the CNS and PT enhancers with the proximal promoter. Constructs were then transfected into HEK293 (embryonic kidney cells), N2A (neuroblastomas), or MO3.13 (hybrid oligodendrocytes) cultures. In MO3.13 cells, the *mAspa* promoter and its derivatives were found to be ten-fold more active than in HEK293s, and three-fold more active than in N2As. Importantly, the relative promoter activities observed in these *in vitro* studies trended towards expression expected of the endogenous *Aspa* gene. We next aimed to examine the *mAspa* promoter *in vivo*. The *mAspa*-derived promoters were cloned into *Egfp*reporter vector constructs and packaged into AAV serotype 9 (AAV9) capsids. We found that neonatal mice injected with vectors carrying the full 3.4-kb *mAspa* promoter (rAAV9-*mAspaP-Egfp*) by facial vein administration conferred nearly equivalent levels of reporter expression in the CNS and liver one month post-injection as mice injected with rAAV9-*CB-Egfp*. However, expression in skeletal and cardiac muscle was absent in mice injected with rAAV9-*mAspaP-Egfp* vectors, while animals treated with rAAV9-*CB-Egfp* vectors exhibited strong expression in these tissues. Surprisingly, the *mAspaP* vectors drove high levels of transduction in brown adipose tissue, while rAAV9-*CB-Egfp* conferred negligible transgene expression. Reporter gene expression in the hippocampus was observed to be most intense in the stratum lacunosum moleculare, while expression was completely absent in the granule cell layer of the dentate gyrus. In contrast, the rAAV9-*CB-Egfp* vector showed abundant expression in the granule cell layer of the dentate gyrus. Our ongoing studies aim to further characterize the *mAspa* promoter and its potential to drive transcription in a diversity tissues, specifically those impacted by Canavan disease.

1595 Systemic Administration and Transient Immunosuppression Eliminate Anti-Drug Antibody Responses Following Vectored Immunoprophylaxis in Mice

Lok Raj Joshi, Evan C. Lam, Meredith Phelps, Alex L. Roederer, Alejandro B. Balazs

The Ragon Institute of MGH, MIT and Harvard, Cambridge, MA

The delivery of broadly neutralizing antibody (bNAb) transgenes using adeno-associated virus (AAV) is a promising strategy for preventing and treating infectious diseases. We have previously shown that AAV-mediated bNAb delivery can protect humanized mice from repetitive vaginal challenges with HIV. In addition, the feasibility of vectored immunoprophylaxis (VIP) as an approach towards sustained HIV suppression has been demonstrated in both humanized mice and non-human primates. Two separate clinical trials employing intramuscular administration of AAV-bNAbs have established the safety and tolerability of VIP. A more recent Phase I study (VRC603) has demonstrated that administration of AAV8-VRC07 results in long-term systemic expression of VRC07 in humans for up to three years. Despite these positive outcomes, these human studies have also identified infrequent development of anti-drug antibodies (ADA) against bNAb as a potential limitation on VIP efficacy. To understand the immune pathways leading to the induction of ADA and investigate new approaches to reduce ADA, we first assessed if the immunocompetent C57BL/6 mouse model could recapitulate the ADA response observed in human studies. Mice given intramuscular injection of 1×10^{11} genome copies (GC) of either AAV1-PG9 or AAV8-VRC07 showed that AAV1-PG9 elicited higher ADA response than AAV8-VRC07, analogous to the results of recent human studies. Similarly, the expression of bNAb was significantly lower in mice that

received AAV1-PG9 as compared to mice given AAV8-VRC07, which maintained high levels of expression for at least 12 weeks. To identify the immune cells responsible for inducing ADA and determine their impact on bNAB expression, we repeated these studies in various immune cell knock-out mouse models. We found that mice lacking B cells or CD4 T cells had significantly reduced ADA and dramatically higher levels of bNAb expression than immunocompetent animals. To evaluate the impact of the route of administration on ADA and bNAb expression, we compared intravenous (IV) and intramuscular (IM) routes of vector administration and found that IV administration elicited significantly lower levels of ADA and higher expression when compared to IM administration. Finally, we assessed the effect of two immune-suppressing drugs, dexamethasone, and cyclosporine, in inhibiting the ADA response and bNAb expression following VIP and found that dexamethasone, but not cyclosporine, inhibited ADA responses and increased antibody expression in the C57BL/6 mouse model. Overall, our finding demonstrates the utility of the C57BL/6 mouse as a pre-clinical animal model capable of recapitulating key aspects of the ADA responses observed in humans. Importantly, the route of AAV administration had a significant influence on ADA response and bNAb expression. Our results also highlight the feasibility of reducing ADA through transient immunosuppression using dexamethasone.

1596 Co-Opting the *SOCS3* Promoter for NK Cell Therapy Using Non-Viral Precision Genome Engineering

Rih-Sheng Huang, Young Vue, Beau R. Webber, Branden S. Moriarity

Department of Pediatrics, Medical School, University of Minnesota, Minneapolis, MN

Natural Killer (NK) cells are a type of innate immune cell able to clear viral infection and malignancy. NK cells represent an allogenic source of immune cells for cancer therapy that perform MHC-independent cell killing, highlighting that NK cells hold a promising future for off-the-shelf cell therapy. Genetic engineering offers further opportunities to enhance the potency of NK cells for immunotherapy. To improve persistence *in vivo*, armoring NK cells with continuous cytokine signaling is essential. Furthermore, chimeric antigen receptors (CAR) can boost the potency of NK cells by providing antigen-dependent activation. Armored CAR-NK cells have been proven effective for liquid tumor treatment and are being tested for effectiveness against solid tumors in several trials. However, uncontrolled constitutive CAR/cytokine expression will lead to off-target toxicity and cytokine storm. In light of this, an inducible promoter is a powerful approach for controlling CAR/cytokine expression in a cytokine-induced manner. Traditional inducible promoter systems rely on antibiotics or small molecule administration, such as doxycycline-inducible and cumate-inducible promoters. Even though these systems have been proven effective *in vitro* and in xenograft mouse models, the usage of xeno-derived genetic components, short half-life caused by liver detoxification, and development into antibiotic resistance remain unsolved. Moreover, vector design of traditional inducible promoter systems often requires the expression of additional transcription factors accompanied by minimal promoter elements in the construct and is restricted to viral delivery methods. To circumvent limitations in current inducible promoter systems, we repurpose the *SOCS3* locus as a cytokine-inducible promoter system by genetic knock-in using non-viral CRISPR-Cas9 genome editing. Synthetic genes driven by *SOCS3* promoter can be induced by cytokines, such as IL-2 and IL-21, which FDA has approved for cancer treatments. Compared to traditional inducible promoter systems, *SOCS3* promoter is purely dependent on the trigger of human-derived cytokines and independent from xeno-derived components. As a proof-of-concept, we knock-in a fluorescent protein into the *SOCS3* locus and systematically profile the regulation of *SOCS3* promoter by different cytokines. Under the optimized cytokine induction, synthetic genes inserted in the *SOCS3* locus can be stably expressed, which also sheds light on autonomous genetic circuit design. Leveraging the pre-existing cytokine-inducible regulation, we aim to engineer state-of-art inducible CAR-NK cells by targeting CAR and other therapeutics genes into the *SOCS3* locus.

1597 Development of a Novel Cell Culture Medium for AAV Production with Multiple HEK293 Lineages and Process Optimization

Jessica J. Haywood[1], Kim Schrag[1], Kate Hellman[1], Nathan Stegemann[1], Katelyn McLaughlin[1], Charlotte Javalet[2]

[1]MilliporeSigma, Lenexa, KS,[2]Merck, KGaA, Meylan, France

Adeno-associated virus (AAV) has become a prominent vector for gene delivery to treat life-threatening genetic diseases. One of the major limitations for product development and treatment availability is the need for high levels of infectious AAV particles, therefore, media and process optimization is vital to achieving high AAV titers. Specific raw materials found in many cell culture media formulations, such as iron citrate, are known to interfere with PEI transfections and must be removed/reduced to enable efficient transfection. Therefore, media development work for HEK293 production of AAV via PEI transfections should target maximizing viable cell density (VCD) and AAV titer, while also enabling PEI transfection. To maximize AAV titers across multiple HEK293 cell lines, media development for AAV production was performed with three HEK293 cell lines with different growth rates. Following media development, transfections were optimized with Design of Experiment (DoE) studies. Finally, bioreactor parameters for growth, PEI transfection, and AAV production were evaluated separately in an Ambr® 15 bioreactor. With this approach, the highest VCD and AAV titers can be achieved without the bottleneck of a non-optimized step in the AAV production process.

1598 AAV-Mediated Gene Therapy Corrects the Severe Phenotype of Acid Ceramidase Deficient Mice

Jérôme Denard[1,2], Martina Marinello[1,2], Virginie Latournerie[1,2], Delphine Bonnin[1,2], Marion Derome[1,2], Samia Martin[1,2], Jeffrey A. Medin[3], Ana Buj Bello[1,2]

[1]GENETHON, Evry, France,[2]University Paris-Saclay, Univ Evry, Inserm, Genethon, Integrare Research Unit UMR_S951, Evry, France,[3]Department of Pediatrics and Biochemistry, Medical College of Wisconsin, Milwaukee, WI

Acid ceramidase deficiency is a group of autosomal recessive lysosomal storage disorder caused by mutations in the *ASAH1* gene that codes

for acid ceramidase (ACDase). This enzyme cleaves ceramide into sphingosine and fatty acid. These ASAH1-related disorders present with a spectrum of clinical manifestations during early (Farber disease, FD) or late infancy/ teenage (spinal muscular atrophy with progressive myoclonic epilepsy, SMA-PME). To date, there is no curative treatment for patients and therefore a clear unmet medical need. We recently established proof-of-concept studies that intravenous administration of a recombinant AAV9 vector expressing human ACDase in *Asah1*$^{P361R/P361R}$ mice at pre- and post-symptomatic stages of the disease is able to prolong the lifespan and correct the phenotype. Here, we performed a dose escalation study in *Asah1*$^{P361R/P361R}$ mice to determine the minimum effective dose (MED) of this vector. Three doses of AAV9-*ASAH1* were administrated intravenously in mutant mice at a late stage of the disease and the effect was analyzed at the clinical, molecular and histological level for a 6-month period. We found that the low dose was suboptimal, whereas most pathological parameters were corrected at mid dose. However, detailed histological analysis of treated mice 6 months post-injection revealed that administration of the vector at the high dose was able to avoid the presence of inflammatory infiltrates in some tissues, including the central nervous system. These results pave the way for preclinical development and clinical translation of this treatment in patients with Farber and SMA-PME diseases.

1599 Engineered Retrogradely Transported, Barcoded AAVs Elucidate Molecular Pathways Involved in the Pathogenesis in Parkinson's Disease (PD)

Martino Avallone[1], Joaquin Pardo[2], Sara Palo[2], Ulrich Pfisterer[3], Jana Rajova[2], Malin Åkerblom[1], Marcus Davidsson[1], Tomas Björklund[2]

[1]Experimental Medicine, University of Lund, Lund, Sweden,[2]Lund University, Lund, Sweden,[3]Division of Clinical Genetics, Center for Translational Genomics (CTG), Lund, Sweden

Here we describe a novel strategy based on AAV engineering and transgenic animals. The MNM008 AAV capsid, capable of retrograde transport in DA neurons, is injected in the striatum of TH-Cre rats and DAT-Cre mice. The vector carries uniquely barcoded aSyn or non-pathogenic tagBFP.Injection into the striatum with Cre-recombinase restriction of the expression to DA neurons of the SN, we avoid possible injection-related inflammation and cell loss. The nuclei from the micro dissected SN area are enriched for DA neurons using FANS. This is achieved thanks to the viral vector prep containing a Cre-inducible histone-linked GFP (H2B-GFP), which is only expressed in the population of interest. Additionally, we used a recently adopted marker (Nurr1) in FANS to study the dopaminergic neurons in WT animals. We tested two emerging and one mature single-cell sequencing approaches. The first one is a single-cell combinatorial fluidic indexing protocol (Scifi) which recently showed to increase the 10X Genomics cells load capacity to 100 folds. The second one is using Parse Bioscience technology, which appends barcodes to each transcript by progressing cells through split-pool combinatorial barcoding steps. This allows to sequence up to 1 M using any standard biology lab equipment. The third approach is using the gold standard 10X Genomics that has been widely adopted in single-cell studies. The molecular barcoding will allow us to accurately measure the aSyn expression level in each DA neuron arranging them into disease stages in what we call pseudo-time. Moreover, this approach will identify causative cascades of changes at the transcriptional level.

1600 Evaluation of an Amphiphilic Graft Copolymer as a Non-Viral Vector for CRISPR/nCas9 on Lysosomal Storage Diseases

Natalia López[1], Jacky Guerrero[1], Katherine Niño[1], Paloma Lemaitre[1], Andres Felipe Leal[1], Lorena Díaz[2], Leon Dario Perez[2], Angela Johana Espejo[1], Carlos Javier Alméciga-Díaz[1]

[1]Instituto de Errores Innatos del Metabolismo, Pontificia Universidad Javeriana, Bogota, Colombia,[2]Departamento de Química, Universidad Nacional de Colombia, Bogota, Colombia

CRISPR/Cas9 has become the current standard for genome editing in several fields. In gene therapy, as observed with the classical approaches, one of the main bottlenecks is the delivery of the genetic material. Although viral vectors show high delivery efficacy, they have been associated with significant side effects, difficulties during scaling-up, and high costs. In this sense, it is important to identify novel vectors that can facilitate the implementation of a greater number of gene therapies, among which nanotechnology-based non-viral vectors represent an important alternative. Previously, we demonstrated that a magneto-liposome vector may allow the delivery of a CRISPR/nickaseCas9 (nCas9) system for the treatment of different lysosomal storage diseases. However, a short shelf-life time of this vector may preclude its use in a clinical scenario. As an alternative in this study we evaluated a novel non-viral vector based on methoxy poly(ethylene glycol) and a hydrophobic block of poly(ε-caprolactone-co-propargyl carbonate) grafted with a predetermined number of poly(2-(dimethylamino) ethyl methacrylate) segments (hereinafter PP6D5). This vector was evaluated for two lysosomal storage diseases (MPS IIIB and Tay-Sachs disease). PP6D5 showed an IC_{50} between 0.99, 0.96, 0.07, 0.013, and 0.007 mM in HEK293 cells, human wild-type fibroblasts, 3T3 mice fibroblasts, U87MG astrocytoma, and SHSY5Y neuroblastoma, showing that central nervous system (CNS) cells are more sensitive to this polymer that fibroblasts. Transfection efficiency evaluation showed that PP6D5 has a similar o even higher transfection rate within the same cells (between 9 and 32%) compared to a lipofectamine-mediated transfection (between 2.6 and 25). For MPS IIIB, gene editing showed higher NAGLU activity levels in HEK293 cells (4 U/mg) and MPS IIIB fibroblasts (4.4 U/mg) compared to lipofectamine (2.3 and 3.6 U/mg, respectively), while in CNS cells increase in enzyme activity was only observed in astrocytoma cells. In the case of Tay-Sachs disease the effects on HexA activity varied depending of the evaluated cell. For instance, in 3T3 fibroblasts higher HexA activity levels (176 U/mg) were observed compared to lipofectamine transfection (132 U/mg), while in astrocytoma cells higher enzyme activity (965 U/mg) were observed with lipofectamine compared to PP6D5 (773 U/mg), and in neuroblastoma none of the strategies led to an expression of the protein. Overall the results showed that this polymer may represent a novel tool for the design of gene editing strategies based on non-viral vectors.

1601 Path to Clinic: Preclinical Pharmacokinetics, Biodistribution and Immunogenicity Strategies to Support First in Man Studies with VSV GP Oncolytic Virus

Michael Franti

DMPK, Boehringer Ingelheim, Ridgefield, CT

The unique properties of oncolytic viruses (OVs) coupled with a dearth of regulatory guidance present challenges for their translation in industry. In particular, their replicative ability distinguishes them from many other therapeutic modalities, and is an important consideration when assessing pharmacokinetics (PK) and biodistribution (BD) in animal models. As their replication may be dependent on host disease state (e.g., tumor burden) and immune status (e.g., pre-existing immunity), tox/biodistribution studies are commonly performed in tumor-bearing animals. Here, we present strategies and approaches employed to bring Vesicular Stomatitis Virus pseudotyped with LCMV glycoprotein (VSV-GP) through IND-enabling tox/biodistribution studies to enable first-in-man trials. Preclinical IND-enabling studies were designed to capture peak periods of viral replication, shedding, and vector persistence, after both intravenous and intratumoral administration in mice. In addition, mechanistic studies were performed to quantify viral PK and replication using a UV-inactivated tool virus, as well as to assess the time course kinetics of immune responses after repeated immunization. For analysis of these studies, a diverse toolset was developed: RT-qPCR, infectivity assays, strand-specific *in situ* hybridization, viral inactivation, and anti-drug antibody (ADA) and neutralization assays. Overall, VSV-GP was well tolerated in healthy and tumor-bearing mice. The predominant distribution sites after intravenous administration were the spleen and liver. As expected, replication was highest in the tumor with minimal/abortive replication and a lack of secondary viremia observed in other tissues and blood. Novel molecular tools and *in vivo* approaches were developed to address the unique PK/immunogenicity considerations of a replicating oncolytic virus. Ultimately, these strategies resulted in successful translation of the VSV-GP platform to the clinic.

1602 Development of Novel Lipoplex Formulation Methodologies to Improve Large Scale Transient Transfection for Lentiviral Vector Manufacture

Thomas Williams[1,2], Carol Knevelman[1], Kyri Mitrophanous[1], James E. Miskin[1], Lee Davies[1], Qasim Rafiq[2]

[1]Oxford Biomedica, Oxford, United Kingdom,[2]University College London, London, United Kingdom

Large-scale transient transfection has advanced significantly over the last 20 years, allowing the effective production of a diverse range of biopharmaceutical products, including viral vectors. New developments and improved transfection technologies are required to ensure that transient gene expression-based bioprocesses can meet the growing demand for viral vectors whilst continuing to consistently manufacture commercial grade viral vectors within strict tolerances for potency, purity, and safety, whilst ensuring high levels of regulatory compliance. When undertaking large-scale transient transfection processes there are challenges related to transfection reagent stability and lipoplex preparation times. We demonstrate the growth of cationic lipid-based liposomes, an essential step in many cationic lipid-based transfection processes, can be controlled through adoption of low pH (pH 6.40 - pH 6.75) and in low salt concentration (0.2X PBS), facilitating improved control over the nanoparticle growth kinetics and enhanced particle stability. Such complexes retain the ability to facilitate efficient transfections for prolonged periods compared to standard preparation methodologies. Liposomes prepared via conventional methods in cell culture medium maintained at a pH of 7.40 achieved particle sizes of 835 nm and 1311 nm after a 5-minute and 15-minute incubation period, respectively. The longer incubation corresponded to a significant reduction in transfection efficiency, from 54.5% to 37.4% ($p<0.0001$), and a 52% reduction in functional lentiviral vector titre ($p<0.0001$). Comparatively, liposomes prepared in culture medium maintained at pH 6.65 achieved particle sizes of 713 nm and 874 nm after prolonged 30-minute and 60-minute incubation periods, respectively, corresponding to equivalent transfection efficiencies of 62.5% and 60.2% ($p=0.9961$) and equivalent lentiviral vector titres ($p=0.6105$). Similar results were obtained when preparing liposomes in low salt concentration formulations. These findings have significant industrial applications for the large-scale manufacture of lentiviral vectors for two principal reasons. First, the alternative preparation strategy enables longer liposome incubation times to be used, facilitating effective control in a GMP setting. Second, the significant improvement in particle stability facilitates the setting of wider process operating ranges, which will significantly improve process robustness and maximise batch-to-batch control and product consistency.

1603 Preliminary Results from a Prospective, Multicentric, Follow Up Standardized Cohort to Assess Natural History of Duchenne Muscular Dystrophy

Vincent Laugel[1], Silvana De Lucia[2], Jb Davion[3], T. Montier[4], C. Espil[5], L. Le Goff[6], B. Chabrol[7], F. Cao[8], S. Balandraud[8], L. Thibaut[8], S. Blaie[8], B. Oswall[9], X. Ni[9], Matthew Furgerson[9], JY Hogrel[10], E. Guemas[11], Francesco Muntoni[12]

[1]Hôpital de Hautepierre, Strasbourg, France,[2]Hospital Trousseau, Paris, France,[3]Service de Neurologie Pédiatrique, CHU Lille, Lille, France,[4]CHRU de Brest, Brest, France,[5]Hôpital des enfants Pellegrin, Bordeaux, France,[6]HFME, Lyon, France,[7]Hôpital d'Enfants, CHU Timone, Marseille, France,[8]Genethon, Evry, France,[9]Sarepta Therapeutics, Cambridge, MA,[10]Institut de Myologie, Pitié-Salpêtrière Hospital, Paris, Paris, France,[11]BIOSSEC, Paris, France,[12]Imperial College London, London, United Kingdom

Introduction Duchenne muscular dystrophy (DMD) is a rare monogenic and progressive neuromuscular disease characterized by functional decline from age 6, loss of ambulation between 8- 15 years of age, and early mortality. Multiple therapies aimed at delaying or stabilizing disease progression are in development. However, the heterogenous clinical course of the disease makes it crucial to understand baseline evolution of assessments to be measured in clinical trials. **Methods** We are conducting an international study in ambulant

DMD boys to assess longitudinally functional measurements prior to roll-over into a gene therapy clinical trial. Enrollment included patients aged from 5-9 years old who were able to cooperate with study assessments and achieved a North Star Ambulatory Assessment (NSAA) score ≥ 18 at inclusion. All patients were assessed using NSAA, timed function tests, MyoTools (upper limb muscles force tests), cardiac and respiratory function tests every 6 months. The analysis here includes 48 patients with at least 6 months follow up (mean= 13.5 months) from France and UK. Descriptive statistics and linear mixed effect model were used to describe the evolution of outcomes. Correlation analyses (Spearman) of these endpoints were performed. **Results** At inclusion, patient's mean age was 7.10 ± 1.37 years, 95.7% were receiving oral steroid treatment (mean duration:14 months), mean weight was 21.76 (±4.03) kg and mean height was116.43 ±9.34 cm. The mean total NSAA score was 25.52 ± 4.24, and mean time to Raise from Floor (TTRFF) was 4.43 ± 1.51s, with NSAA means being similar between patients < 7 and ≥7 years of age at screening. mean Forced Vital Capacity (FVC) and Forced Expiratory Volume in one second (FEV1) were 90.35±18.85 % predicted and 92.83±17.72 % predicted. Physical function tests scores were mostly stable or improving over time in younger patients, whereas they tend to decrease in older patients: e.g., NSAA slope of -0.07 (95% CI: [-1.79; 1.65] p=0.9341) in patients < 7yo and -3.19 (95% CI: [-5.03; -1.35] p=0.0011) in those ≥ 7yo at 12 months. The same trend was observed in pulmonary tests, suggesting early respiratory muscle decline at time of lower limb decline. NSAA, Time to 10 Meters Walk/Run Test (10MWT) and TTRFF correlated well between each other (Rho between 0.75 and 0.81). Upper limb force measurements (Myopinch and Myogrip) remained stable during follow-up and were not correlated with other functional tests, consistent with other reports of the trajectories of upper limb decline occurring later in disease progression. **Conclusions** This is a natural history study in DMD with a standardized follow-up and outcome measurements. The findings reinforce the need to include multi-measures for accurate outcome assessment in clinical trials with DMD, as different assessments decline at different rates and at different timepoints. It also supports to use NSAA as primary endpoint in this younger ambulatory population. These early results suggest that the monitoring of respiratory function may be useful to detect early divergence from expected trajectories for study-drug evaluation. More longitudinal data are being collected for a more robust and comprehensive analysis.

1604 Evaluation of Transcytosis Receptor Expression Between Human Brain Endothelial Cells *In Vitro* and *In Vivo* with Respect to Adeno-Associated Virus Capsid Selection

Jeffrey D. Rubin, Aranyak Goswami, Mark A. Kay
Departments of Pediatrics and Genetics, Stanford University School of Medicine, Stanford, CA

The ability of adeno-associated virus (AAV) capsids to pass from the blood to the brain after intravenous infusion is crucial for being able to treat genetic diseases of the brain. Movement of AAV capsids across the blood-brain barrier (BBB) relies upon the process of transcytosis, in which the AAV capsid binds to a particular transcytosis receptor in the blood vessel lumen and transports through an endothelial cell into the parenchyma of the brain. Since naturally occurring serotypes of AAV have limited ability to undergo transcytosis, many efforts are ongoing to engineer capsids with increased transcytosis efficiency. One powerful engineering method is directed evolution of AAV capsids, in which a randomized library of genetically modified capsids is put through a selection process to identify new capsids with specific properties. The selection process utilized determines the properties of the resulting capsid(s), with notable cases where capsids selected to cross the BBB *in vivo* in mice have properties that do not translate to other species. Recently, our lab used a human transwell system, which allows for selection of capsids that can cross the human BBB, rather than a model organism. After isolating subsets of shuffled capsids that crossed the BBB and had a bias for transducing either astrocytes or neurons, an siRNA screen was performed to identify known human transcytosis receptors that might facilitate transport of these novel capsids. In the current study, we sought to better understand transcytosis receptor gene expression in hCMECs. To generate an overview of gene expression in the cells, mRNA-seq was performed on cultured wildtype hCMECs (n = 6). Surprisingly, for *MSR1*, the leading transcytosis receptor candidate from the siRNA screen, transcripts were not detected, at 0 transcripts per million (TPM). The next top five hits from the siRNA screen, *SCARB1*, *SCARA3*, *IGF1R*, *FCGRT*, and *LEPR*, were measured at 68, 90, 142, 18, and 80 TPM, respectively. These relatively low expression levels contrast with the mostly highly expressed putative transcytosis receptors we noted, which were *BSG*, *SLC7A5*, *PICALM*, *TFRC*, *IGF2R*, measured at 527, 354, 339, 263, and 231 TPM, respectively. We cross-referenced this mRNA-seq data to the most robust online human brain vascular atlas and found that *IGF1R*, *PICALM*, *BSG*, and *SLC7A5* had the highest expression from a set of putative transcytosis receptors in arterial, capillary, and venous cells, sharing some similarity with relative expression in hCMECs. In addition, the atlas revealed that the *MSR1* gene is only significantly expressed in peripheral macrophages *in vivo*, rather than vascular cells. In comparison to humans, the literature shows that *IGF1R* is expressed at the same relative level in mouse brain endothelial cells (BECs), however, *PICALM* is expressed at approximately twice the level in human BECs compared to mouse BECs. Overall, the data presented here show that a complete receptor knockout is important to validate artifacts that may arise from an siRNA receptor knockdown screen, generation of an mRNA-seq library of cells used for selection is an informative tool, and there are interesting parallels between human transcytosis receptor expression *in vitro* and *in vivo*. Future work will include creation of new knockout hCMECs to gauge interaction with AAV capsids and measurement of transcytosis receptor transcripts from the brains of non-human primates that will be used for preclinical testing.

1605 Production of High AAV Titers in Upstream Manufacturing Using Small Molecule Enhancers

Rebecca M. Reese[1], Jennifer Swanson[1], Austin Storck[2], Laura Juckem[1]
[1]Mirus Bio, Madison, WI,[2]Mirus Bio LLC, Madison, WI

In recent years, there has been an exponential increase in the number of registered clinical trials examining the use of recombinant adeno-associated virus (AAV)-based gene therapies. Upstream production of AAV therapies is driven by transient transfection of suspension cells with multiple plasmid DNA constructs

encoding essential virus proteins. AAV therapies require high titers of viral genomes per dosage, prompting the need for more efficient methods of AAV manufacturing to reduce overall costs. Recently, we identified a library of small-molecule enhancers which can be optimized in conjunction with a variety of upstream AAV production parameters. These cutting-edge small molecules enhancers were tested with state-of-the-art transfection technologies developed within our group. DOE was performed to find the optimal conditions in which each small molecule would produce the highest AAV titers. These small molecules were not detrimental to transfection efficiency and each produced high-quality titers across a range of suspension HEK 293 subtypes, cell growth media, and cell densities as measured by viral genomes and the percentage of full capsids. To address scalability, we performed experiments in a stirred tank bioreactor (STR) up to 2L. Additionally, there was no difference in the effectiveness of these small molecules across a range of different plasmid DNA vectors encoding essential genes for recombinant AAV production. Multiple serotypes were assessed, including AAV2, AAV5, AAV8 and AAV9. Interestingly, certain small molecules were more effective at increasing AAV titers in some serotypes over others. Overall, our data demonstrate that due to the complex nature of AAV manufacture, it is advantageous to screen different small molecule enhancers during process development. Improvement of titers has broad implications for the economical manufacturing of high dose assets and mainstream utilization of AAV gene therapy.

1606 Detection of Gene Editing of the Dystonia (DYT1) Mutant Allele with Extracellular Vesicles

Katia Maalouf[1], Dawn M. Frederick[1], Christine A. Vaine[2], D. Cristopher Bragg[2], Benjamin P. Kleinstiver[3], Xandra O. Breakefield[1], Koen Breyne[1]

[1]Molecular Neurogenetics, Massachusetts General Hospital, Charlestown, MA,[2]Neurology, Massachusetts General Hospital, Charlestown, MA,[3]Center for Genomic Medicine, Massachusetts General Hospital, Boston, MA

DYT1 dystonia is a hereditary neurological movement disorder with a 3-bp hallmark deletion (c.907 909delGAG) in the *TOR1A* gene. This dominant-negative mutation is believed to compromise function of normal torsinA. TorsinA is located in the endoplasmic reticulum and has a role in protein processing, transport across the nuclear envelope and movement of nuclei. In this study, we aim to lower mutant torsinA levels and restore healthy torsinA activity in the basal ganglia of mouse brains. We used our previously established gene editing approach to disrupt the DYT1 allele with an engineered Cas9 variant from *Staphylococcus aureus* (SaCas9-KKH). As readout for effective disruption of mutant torsinA allele in DYT1 patient fibroblasts and human neuropreursor cells (hNPCs) derived from patient induced pluripotent stem cells, we analyzed the ratio of mutant and wild type torsinA mRNA in extracellular vesicles released from these cells. EVs were isolated from cell media and their RNA payload was assessed with a newly developed TaqMan-probe-based assay which distinguishes between the WT and mutant torsinA mRNAs. This readout was matched to the genotypic situation in the EV-donor cells. We are currently engrafting the brains of mice with patient-derived hNPCs prelabeled with a CRE reporter as a gene therapeutic screening method injecting AAV- CRE vector. EVs released from implanted cells into the bloodstream are isolated and evaluated using the TaqMan assay in addition to next-generation CRISPR sequencing as a readout for % of Cre-mediated editing. Overall, our technique provides a method to screen the efficacy of changing gene sequence in patient-derived cells implanted in the brain in response to gene therapy treatment, which is applicable to testing this genome-modifying therapy in preclinical DYT1 models.

1607 Preclinical Efficacy and Safety Study of AAVrh10-*GRN* Gene Therapy to Treat Frontotemporal Dementia Caused by Granulin Mutations

Khalid Arhzaouy

AGTC (Applied Genetic Technologies Corporation), Cambridge, MA

Frontotemporal dementia (FTD) or frontotemporal lobar degeneration (FTLD) is one of the most common causes of early onset dementia. The disease is characterized by progressive degeneration of neurons in the brain's frontal and temporal lobes leading to changes in personality, behavior, and language. Up to 10% of FTD cases are caused by dominant loss-of-function mutations in the granulin (*GRN*) gene, resulting in > 50% reduction of progranulin levels. Currently, there are no disease-modifying therapies available for patients with FTD-*GRN*. In this study, we evaluated the efficacy of adeno-associated virus (AAV) gene therapy for the treatment of FTD-*GRN* by delivering AAVrh10-*GRN* (AGTC-601) to the CNS of adult homozygous Grn^{R493X} mouse model ($Grn^{R493X/R493X}$) via intracerebroventricular (ICV) injection. GLP Toxicity and biodistribution studies are in progress in adult Cynomolgus Monkeys following a single intracisterna magna (ICM) administration of AGTC-601 into the cerebrospinal fluid (CSF) at different doses. Grn^{R493X} treated mice did not show any behavioral abnormalities throughout the entire study. Human progranulin (hPGRN) expression levels were sustained in mice brain including Frontal Cortex, Hippocampus, and Thalamus for up to 6 months. The treatment rescued the lysosomal dysfunction in Grn^{R493X} mice by reduction of the accumulated lysosomal lipofuscin and the decrease in the elevated LGALS3 (Galectin-3) levels in mice brain. The ICM delivery of AGTC-601 in NHP was well tolerated with no associated adverse findings in-life at the tested doses and resulted in a sustained expression of hPGRN in the CSF for > 6 months. Interestingly, the use of a neuron-specific promoter restricted hPGRN expression to the CNS. Together, these studies support further development of AGTC-601 as a potentially one-time treatment for FTD-*GRN*.

1608 Functional Human Ovarian Granulosa-Like Cells Generation from Stem Cells via Network-Informed CRISPR Activation Screening

Lin Zhao, Pranam Chatterjee

Biomedical Engineering, Duke University, Durham, NC

Human granulosa cells (hGCs) play a key role in female reproduction by regulating human oogenesis and folliculogenesis in the ovary. The dysfunction of granulosa cells can lead to disorders of human ovarian function, such as polycystic ovary syndrome, premature ovarian failure, and granulosa cell tumors. However, the lack of reproducible cellular systems suitable to investigate the molecular mechanisms underlying ovarian development in

humans have hampered studies on granulosa cell differentiation. In this project, we create a novel system to differentiate human inducible pluripotent stem cells (hiPSCs) into hGC-like cells (hGCLCs) in vitro via activation of key transcription factors (TFs). We first employ a graph theory-based strategy, by constructing a gene regulatory network (GRN) representation of natural hGC differentiation and then employing centrality algorithms to prioritize the critical TFs that govern the hGC GRN. To experimentally validate TFs, we then leverage the CRISPR activation (CRISPRa) system for high-throughput screening. By employing fluorescent reporters of several key marker genes, such as FOXL2 and AMHR2, we validate master regulators of hGC fate specification, such as NR5A1, RUNX2, and GATA4, and further isolate guide RNAs activating novel regulatory TFs that enhance hGC differentiation. Furthermore, via lentiviral integration of identified TFs, we conduct functional and molecular phenotyping of hGCLCs and detect high levels of estrogen and progesterone, indicating that our derived hGCLCs retain characteristics of endogenous ovarian granulosa cells. Overall, we envision that our rapid 5-day hGCLC induction protocol will serve as a significant milestone in the effort to generate human ovarian follicles in vitro and establish a deeper understanding of the female reproductive system. Moreover, our system may also serve as a replenishable reservoir for healthy hGCs and enable potential cell therapeutic solutions for ovarian diseases.

1609 *In Vivo* Gene Editing of Murine Hematopoietic Stem Cells via AAV-Delivered CRISPR Guide RNAs

Alborz Karimzadeh[1], Michael Florea[2], Bryan Peacker[2], Shio Kobayashi[1], Drake Watkins[1], Kathleen Messemer[2], Thomas F. Serwold[1], Amy Wagers[1,2]

[1]Joslin Diabetes Center, Boston, MA,[2]Harvard, Cambridge, MA

Hematopoietic stem cells (HSCs) are the self-renewing, multipotent, and engraftable source of all cells in the blood system. Accordingly, hematopoietic stem cell transplantation (HSCT) has been utilized as a definitive cure for hematological disorders. Although HSCT has been improved upon for decades, associated complications still make this approach a last-resort option in many cases. Efficient *in vivo* gene editing of hematopoietic stem cells (HSCs) has the potential to eliminate the requirement for HSCT while still leveraging the potency of HSCs for blood cell repopulation in treating monogenic blood disorders. Towards this aim, we used adeno-associated virus (AAV) to deliver CRISPR guide RNAs (gRNAs) to gene edit HSCs *in vivo* in an Ai9;Cas9-eGFP reporter transgenic model. This model carries a modified ROSA26 locus, in which one allele encodes a Cas9-activatable Lox-STOP-Lox (LSL)-TdTomato reporter cassette and the other a constitutive SpCas9-2A-GFP. We tested whether systemic administration to these mice of AAVs carrying SpCas9-compatible gRNAs designed to induce cuts upstream and downstream of the STOP cassette would result in TdTomato expression in HSCs. Administration of AAVs carrying one copy of each guide ("1x gRNAs") in adults yielded rare, but readily-detectable, gene edited HSCs. We then tested whether modifications to our vector system might improve editing rates by utilizing a) self-complementary AAVs (scAAVs) and b) additional guide copies for the upstream and downstream guides ("2x gRNAs"). scAAV-1xgRNAs improved editing rates by ~6-fold compared to single-stranded AAV-1xgRNAs. Inclusion of an additional copy of each guide also improved editing rates in immunophenotypic HSCs by ~25%. With these modifications, we reached ~5% HSC gene editing in adult animals injected with scAAV-2xgRNAs. Furthermore, we found ~20% editing in HSCs when neonatal animals were injected with scAAV-2xgRNAs. To apply our approach to a disease-related gene, we generated sickle-cell disease (SCD) mouse models ("Townes" model) expressing SpCas9-eGFP from the ROSA26 locus, referred here as SCD;Cas9-eGFP. These animals have mouse HBA and HBB replaced with human HBA, HBB or HBS (healthy or sickle HBB), and HBG. Mice homozygous for HBS show SCD phenotypes similar to SCD patients. Studies are currently ongoing to determine whether we can apply our *in vivo* gene editing system to disrupt the binding site for BCL11a (a silencer of fetal hemoglobin) in the human HBG promoter of these mice, thereby elevating fetal hemoglobin production, which has been put forward as a therapeutic strategy to combat SCD. In conclusion, we introduce a system for *in vivo* gene modification of HSCs in mice and define several necessary components required for robust editing.

1610 Gold Nanoparticle-Mediated Gene Editing for Long Transgene Delivery *In Vivo*

Rachel Cunningham[1,2], Karthikeya S. V. Gottimukkala[1,2], Daniel D. Lane[1,3], Molly E. Cassidy[1], Lois Bayigga[1], Youngseo Jwa[1], Jack M. P. Castelli[1,2], Justin J. Taylor[4,5], Jennifer E. Adair[1,3]

[1]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA,[3]Department of Medical Oncology, University of Washington, Seattle, WA,[4]Vaccine and Infectious Diseases Division, Fred Hutchinson Cancer Center, Seattle, WA,[5]Department of Immunology, University of Washington, Seattle, WA

Gene editing using CRISPR has gained traction for its potential to treat various diseases. However, current gene editing therapies are hampered by delivery. While gene-edited cell products engineered ex vivo are largely effective, they are time and resource intensive to produce. Development of an effective in vivo therapy could overcome these limitations. Our lab developed a gold-based nanoparticle to simultaneously deliver CRISPR RNP and ~100bp single-stranded (ss)DNA templates (CRISPR-AuNP). Thiol-modified guide (sg)RNA binds a Cas12a nuclease to the AuNP core. This is coated in a cationic polymer to mediate endosomal escape. This polymer is coated in DNA template. Recent studies show this nanoparticle can carry templates as long as ~2.5kb. Here we tested CRISPR-AuNP for in vivo gene editing of the human immunoglobulin heavy chain (*IGH*) locus to introduce an engineered transgene. To evaluate the efficacy, we compared two formulations, A and B, based on characterization of our published CRISPR-AuNP formulation [2023-A-1421-ASGCT]. Formulation A followed published synthesis procedures. AuNP were incubated with modified sgRNA prior to conjugation with Cas12a. These particles were then coated in polyethylenimine (PEI) and incubated with double stranded (ds)DNA templates encoding a CMV-GFP reporter construct with homology arms to the human *IGH* locus. Formulation B was made by incubating pre-conjugated Cas12a RNP with AuNP, and then coating in PEGylated PEI prior to dsDNA addition to further stabilize the particle at physiological conditions. Both formulations were stable and monodisperse (A/B: hydrodynamic diameter =

65.9nm/64.8nm, polydispersity index = 0.19/0.18) in solution as measured by dynamic light scattering (**Figure 1B**). These CRISPR-AuNP were administered to humanized mice (**Figure 1A**) to evaluate delivery in vivo to hematopoietic cells. NOD/SCID/gamma null (NSG) mice were engrafted with human CD34+ cord-blood derived stem cells via intrahepatic injection at 1-2 days of age following sublethal total body irradiation. At 8 weeks, peripheral blood was evaluated for human cell engraftment and lineage development. Mice received three total CRISPR-AuNP injections bi-weekly beginning at week 9, each containing 1.5mg/kg of treatment A or B into the femur, the most accessible repository of human CD34+ cells in humanized mice. Injections alternated weekly with retroorbital bleeds. Following each injection we evaluated peripheral hCD45+hCD20+ B cells, the therapeutically relevant population for *IGH* editing. GFP expression was observed in 0.03% of B cells in group B mice (**Figure 1C**), increasing 0.12% and 0.23% respectively over the next month. Sequencing of the *IGH* locus in whole peripheral blood revealed indels at the target cut site with 2.4% overall gene editing for A and 5.2% for B (**Figure 1D**). Off target tissue analysis is ongoing. The successful expression of a long transgene in B cells in vivo suggests that CRISPR-AuNP are a viable method for in vivo transgene insertion at the *IGH* locus.

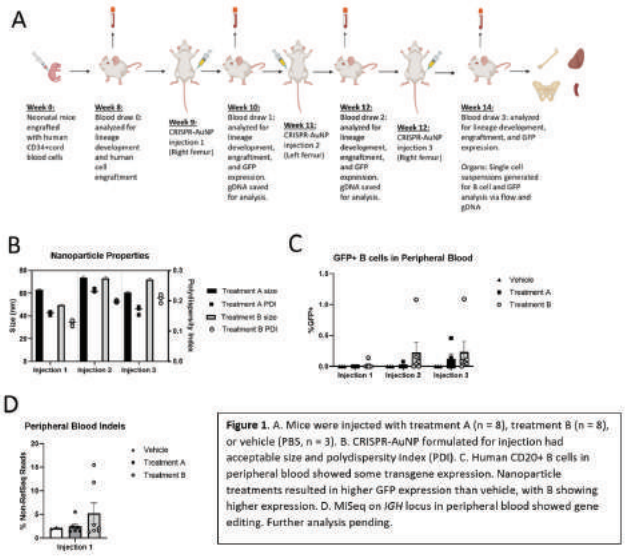


Figure 1. A. Mice were injected with treatment A (n = 8), treatment B (n = 8), or vehicle (PBS, n = 3). B. CRISPR-AuNP formulated for injection had acceptable size and polydispersity index (PDI). C. Human CD20+ B cells in peripheral blood showed some transgene expression. Nanoparticle treatments resulted in higher GFP expression than vehicle, with B showing higher expression. D. MiSeq on *IGH* locus in peripheral blood showed gene editing. Further analysis pending.

1611 *In Vivo* Editing of the *HAO1* Gene with ABR-001, a Novel Type V CRISPR Cas, Leads to Significant Reduction in Toxic Oxalate in a Mouse Model of Primary Hyperoxaluria Type 1

Michael S. Kuefner, Sneha Halwasia, Sonya V. Iverson, Sejuti Sengupta, Jeffrey R. Haswell, John E. Murphy, Tia DiTommaso

Arbor Biotechnologies, Cambridge, MA

Primary Hyperoxaluria is an inherited rare disease that results from the abnormally high production of the insoluble metabolite oxalate. This results in calcium oxalate crystal formation and deposition in the kidney and other tissues, resulting in painful kidney stones, renal failure, and other severe consequences of systemic oxalate deposition, traditionally treated by combined liver/kidney transplants or more recently, by lifelong siRNA therapy. Primary Hyperoxaluria type 1 (PH1), results from mutations in the *AGXT* gene, which encodes hepatic peroxisomal enzyme alanine glyoxylate aminotransferase (AGT) and converts the metabolite glyoxylate to glycine and pyruvate in the liver. In the absence of AGT enzyme, glyoxylate is converted to oxalate by lactate dehydrogenase. Glyoxylate, is primarily formed by the conversion of dietary glycolate by the enzyme, glycolate oxidase (GO), encoded by the *HAO1* gene. One strategy to treat PH1 is to block the activity of GO, reducing toxic oxalate burden by preventing formation of its precursor, glyoxylate and increasing production of glycolate, which is soluble and readily excreted compared to oxalate. Genetic inactivation of the *HAO1* gene through CRISPR Cas editing is an attractive alternative for treatment of severe PH1. Early exons of either human or mouse HAO1 genes were targeted with ABR-001, an engineered variant of Cas12i2, yielding indels in cultured cells. To understand the *in vivo* pharmacology of *HAO1* editing, synthetic modified guide RNAs (gRNAs) were packaged with an mRNA encoding ABR-001 in an LNP. A dose response study was performed in wild-type mice at doses ranging from 0.5-2.0 mg/kg total RNA. Editing, as determined by NGS, reached a maximum at 1 mg/kg and was primarily seen in liver. Characteristic of type V enzymes, the edits were primarily small deletions, predicted to disrupt protein production. Concomitant with editing, was a dose responsive rise in plasma glycolate (>10-fold above baseline), demonstrating expected modification of the metabolic pathway. Further studies were performed in a mouse model of PH1. LNPs, described above, were administered to AGXT deficient mice at doses of 1.5 and 3.0 mg/kg and mice were followed for three weeks. The level of plasma glycolate increased 8-10-fold following treatment. Importantly, the level of urinary oxalate was reduced by about 40%, to a therapeutically relevant range within one week of treatment and remained reduced throughout the three-week study. Editing, as determined by NGS, was approximately 60% for both groups, with slightly higher indels for the 3.0 mg/kg group. Analysis of GO enzyme activity in harvested liver fractions showed significant knockdown in the 1.5 mg/kg group and complete ablation in the 3.0 mg/kg group. These results provide *in vivo* proof of pharmacology for a gene editing approach to PH1 using a novel type V CRISPR Cas system.

1612 AAV Vector SKG0301 Exhibits Therapeutic Potential in a Pompe Mouse Model

Yu Wu, Xiaorui Bian, Yanjun Liu, Ruoyan Hu, Shihua Cao, Yanjun Shen, Lu Wang, Xinyi Wu, Xing Ding, Li Wang, Carol Huang, Ting Yu, Jay Hou

Skyline Therapeutics, Cambridge, MA

Pompe disease (glycogen storage disease type II) is a severe disorder caused by loss-of-function mutations in the human *GAA* gene encoding acid α-glucosidase. Deficiency of this enzyme results in accumulation of glycogen in lysosomes, impairing muscular and cardiac function. Enzyme replacement therapy (ERT) is the standard of care for Pompe disease, but this approach has several limitations including a short half-life of the drug that requires life-long bi-weekly infusions and an anti-drug antibody (ADA) response that leads to reduced efficacy.

To address these challenges, we explored the strategy of gene therapy by constructing and producing an AAV9 vector expressing a codon-optimized human *GAA* transgene, which would express GAA in muscle and cardiac cells in a durable manner upon a single intravenous administration. Among all the constructs we had screened, SKG0301 showed superior GAA expression levels in the target tissues with little immunogenicity. Systemic delivery of SKG0301 in adult *Gaa*$^{-/-}$ mice, a model of Pompe disease, resulted in a dose-dependent increase in GAA activity, clearance of glycogen in the muscles and heart, rescue of motor function, and extension of survival. These effects were lasting and therapeutically meaningful. In addition, the vector was well-tolerated by the animals. In summary, gene therapy is a viable approach for the treatment of Pompe disease. Our data suggest that SKG0301 is a promising drug candidate with potential therapeutic benefit for patients with the disease.

1613 A Sickle HUDEP2 Cell Model with GFP/BFP Tagged Beta-Globin to Examine Its Regulation in Treating β-Hemoglobinopathies and Disorders of Erythropoiesis

Cecile L. Karsenty[1], So Hyun Park[2], Gang Bao[2]

[1]Department of Pediatrics, Cancer and Hematology Centers, Baylor College of Medicine, Houston, TX,[2]Department of Bioengineering, Rice University, Houston, TX

Sickle cell anemia (SCA), a β-hemoglobinopathy, is a severe inherited monogenic disorder. It is caused by a point mutation in the beta-globin gene (*HBB*), leading to the replacement of glutamic acid by valine at the sixth residue. The resultant protein is hemoglobin S (HbS). One approach in treating SCA using CRISPR/Cas9 based gene editing relies on correcting the pathogenic point mutation in *HBB* via the homology-directed repair (HDR) pathway by delivering Cas9/gRNA and a corrective donor template. We found that, although HDR rates are high (~40%), about 42% of CRISPR/Cas9 induced DSBs are repaired via non-homologous end joining (NHEJ), resulting in small insertions and deletions (indels) at the Cas9 cut site as well as a high frequency of large gene modifications including large deletions (up to 4350bp). Small frameshift indels can introduce a premature stop codon and disrupt the expression of the target gene. With small in-frame indels the gene can still have transcription, resulting in proteins that are functional, partially functional, or pathogenic. Large deletions can cause gene disruptions, raising a concern of *HBB* gene knockout and the risk for known pathogenic phenotypes such as β-thalassemia. These CRISPR/Cas9 induced on-target modifications result in diverse and heterogeneous genotypes which may in turn lead to deleterious phenotypes. Due to this heterogeneity and short life span of terminally differentiated HSPCs, it is difficult to link a specific genotype to an observed phenotype. We aim to develop a fluorescent cell model to monitor allele specific *HBB* expression in live cells. With this tool, we will be able to assess the downstream consequences of *HBB* gene modifications and evaluate gene editing targets for SCA. Sickle Human Umbilical Cord Derived Erythroid Progenitor cells (S-HUDEP2) are immortalized CD34^{+} hematopoietic stem and progenitor cells with homozygous sickle mutation that exclusively produce HbS upon erythroid differentiation. We established a clonal S-HUDEP2 fluorescent model by labelling each *HBB* allele with a fluorescent protein (GFP or BFP) via tagging at C-terminus of *HBB* with a P2A self-cleaving peptide (HBB$^{GFP/BFP}$). In this model, GFP/BFP expression is under direct control of the *HBB* promotor and bi-allelic *HBB* tagging was confirmed by sequencing. To validate this model, we delivered HiFi *Sp*Cas9/sgRNA as ribonucleoprotein (RNP) via electroporation using the two sgRNAs targeting the sickle mutation currently in pre-clinical and early phase clinical trials (R-66S and R-02 respectively). Efficient editing was confirmed via Inference of CRISPR Edits (ICE) analysis. We conducted *in vitro* expansion of edited clones. Using FACS, we observed distinct populations based on GFP/BFP fluorescent intensity (negative, low, medium, high) in edited clones compared to mock treated controls. We sorted 4 distinct populations based on fluorescent expression: (i) GFP^{high}/BFP^{high}, (ii) GFP^{high}/BFP^{Low}, (iii) GFP^{low}/BFP^{high}, (iv) GFP^{low}/BFP^{low}. From each population, genomic DNA was extracted for digital droplet PCR (ddPCR) probe-based copy number assay to identify large deletions (>37bp) and for ICE analysis to identify small indels. These analyses confirmed enrichment of large deletions and frameshift indels in the GFP^{low}/BFP^{low} sub-populations and each group exhibited a unique indel profile based on GFP and BFP expression. The gRNA-specific indel profiles demonstrated our cell model's ability to identify diverse *HBB* repair outcomes. In summary, we have established a S-HUDEP2 cell model allowing for monitoring allele specific *HBB* expression based on fluorescence and directly correlating genotype and phenotype. This cell model can be used as a tool to evaluate the efficiency and safety of gene editing based therapy for SCA.

1614 Electroporation-Mediated Gene Delivery of the Na^{+},K^{+}-ATPase β1 Subunit to the Esophagus Induces Tight Junction Expression and Prevents Dilated Intercellular Space (DIS) Formation in a Rabbit Model of GERD

Gillian M. Schiralli Lester[1], Michael Barravecchia[1], Jing Haung[2], Jennifer Young[1], Zhongren (David) Zhou[2], David A. Dean[3]

[1]University of Rochester Medical Center, Rochester, NY,[2]Rutgers University, New Brunswick, NJ,[3]University of Rochester, Rochester, NY

Gastroesophageal Reflux Disease (GERD) is characterized by the erosion of the esophageal mucosal lining caused by recurrent stomach and bile acid exposure. In reflux disease gastro-duodenal contents regurgitate into the distal esophagus due to an incompetent lower esophageal sphincter. The bathing of the lower esophagus with stomach acid and bile acids results in the formation of dilated intercellular space (DIS) which is a pathological feature of GERD. DIS and the loss of barrier function of the epithelium caused by cellular injury also results in the disruption of tight junctions. We have found a reduction in transepithelial resistance (TEER) in our immortalized primary esophageal keratinocyte stratified squamous cell culture system upon treatments with bile salts at low pH. We have also seen a marked reduction in Occludin staining, a tight junction protein, in esophageal tissue samples from patients with GERD as compared to normal control tissue. These findings highlight the disruption in epithelial tight junctions under reflux disease conditions. Our laboratory has previously shown that overexpression of the β1 subunit of the Na^{+},K^{+}-ATPase results in the increased expression of tight junction proteins and restores epithelial barrier function in lung tissue.

Therefore, we hypothesized that maintaining and reinforcing epithelial barrier function in the distal esophagus through the modulation of tight junction proteins via gene delivery of the Na^+,K^+-ATPase β1 will prevent DIS and GERD symptoms in vivo. We have developed an electroporation-mediated gene transfer procedure to deliver naked plasmid DNA to the distal region of the esophagus in healthy rats and rabbits. Our gene transfer technique yielded robust transgene expression in rats as early as 48 hours post transfection (CMV-Luciferase) which persisted as long as 6 and 12 weeks (UbC-Luciferase) post transfection. We next tested our gene delivery procedure in the context of an established rabbit GERD model. In this system, Norwegian white rabbits are given GERD and DIS via a total 360° cardiomyectomy procedure which strips the controlling musculature of the gastric sphincter resulting in incompetent sphincter control and the formation of DIS by 12 weeks post procedure. We have delivered the Na^+,K^+-ATPase β1 subunit or a matched GFP control plasmid via electroporation at the time of cardiomyectomy to the exposed distal esophagus. After the completed surgical procedure and electroporation, the rabbits recover and are housed for a duration of 12 weeks. A clear induction of DIS is present in animals that underwent cardiomyectomy and received the GFP vector control plasmid. By contrast, rabbits that underwent cardiomyectomy and received the Na^+,K^+-ATPase β1 showed marked levels of protection from DIS formation as determined by electron microscopy**.** Our findings show that gene transfer of the Na^+,K^+-ATPase β1 subunit upregulates tight junction abundance and activity to improve barrier function in the esophagus and provides a degree of protection from development of DIS, a hallmark for GERD.

1615 Efficacy and Safety Assessments of AAV-Mediated CYP4V2 Augmentation for the Treatment of Bietti's Crystalline Dystrophy

Qing Cao[1], Hai Zhang[1], Biao Wang[1], Zhiyong Cao[1], Shengmei Wen[1], Yiting Liu[2], Guang Qu[1,2], Lixin Jiang[1,2]
[1]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, China,[2]NGGT Inc, Walnut Creek, CA

Introduction: Bietti's crystalline corneoretinal dystrophy (BCD) is a rare-inherited disease characterized by the presence of multiple shimmering yellow-white deposits in the fundus of patients in association with atrophy of the retinal pigment epithelium (RPE) and chorioretinal atrophy. The onset of the disease usually occurs between the teenage years and the age of 30. As the disease progresses, most patients become blind in the age of 40 to 50. BCD is caused by mutations in the cytochrome P450 (CYP) family 4 subfamily V member 2 gene (*CYP4V2*) encoding a polyunsaturated fatty acid hydroxylase which is dominantly expressed in RPE cells in retina. Currently, there is no treatment available for BCD. **Methods/Results:** We have developed NGGT001, an rAAV2-based vector expressing codon optimized human *CYP4V2* for treating BCD. Using CRISPR-Cas9 gene editing, we generated two human cell models carrying *CYP4V2* pathogenic mutations. These *CYP4V2* mutant cell line models exhibited several typical cellular defects observed in lesion-affected cells from patients with BCD, such as deficits in cell proliferative activity, autophagy, and lipid metabolism. Expression of CYP4V2 mediated by NGGT001 effectively rescued phenotype defects caused by *CYP4V2* mutations in these two BCD-relevant cell models, as demonstrated by restored autophagy flux activity, reduced lipid accumulation and preserved cell viability under lipid challenge, providing the therapeutic concept of function restoration by *CYP4V2* gene augmentation. Furthermore, stable vector transduction and long-term expression of CYP4V2 protein were achieved in the ocular compartments by a single subretinal injection of NGGT001 in WT mouse and in a knock-out mouse model of *Cyp4v3*, the mouse ortholog of human *CYP4V2*. In adult Cynomolgus monkeys administrated with subretinal injection of a single dose of NGGT001, robust vector distribution and sustained *CYP4V2* mRNA expression were observed in retinal and choroid tissues. Sufficient and persistent levels of CPY4V2 expression in the animal eyes supported the long-term therapy efficacy of function augmentation. In Brown Norway rats and in Cynomolgus monkeys following a bilateral single subretinal injection, NGGT001 induced limited inflammation and minimal test article-related changes in ophthalmic examinations and pathology during the 13-week toxicology studies. Vector DNA and transgene mRNA were mainly detected in ocular tissues, a small amount in liver and spleen and not in the whole blood. Thus, subretinal administration of NGGT001 was generally well tolerated. **Conclusions:** Taken together, our efficacy and safety studies demonstrated the safety of NGGT001 and highlighted that NGGT001 achieved stable expression of active CYP4V2 protein and restored lipid metabolism in the retinal cells. These results support the clinical deployment of NGGT001 as a promising gene therapy treatment for BCD.

1616 ATLAS: A High-Throughput Gain and Loss-of-Function Screening Platform for Optimizing AAV Production

Chris Reid, Francis Grafton, Lily Leveque-Eichhorn, Jinna Brim, Isha Ukani, Kaylin Fisher, Mo Mandegar
Innovation Hub, Ascend GCTx, San Francisco, CA

Recombinant AAV is one of the most widely used vectors for in vivo gene delivery. There are currently over 900 ongoing pre-clinical and clinical programs using AAV which all require significant manufacturing capacity. Inefficiencies in current manufacturing techniques has ultimately resulted in extremely high cost of gene therapy drug products. This severely limits the widespread use of AAV-mediated gene therapies for common and rare indications. In this study we present ATLAS (Arrayed Targeted Library for AAV Screening) a modality-agnostic, high-throughput screening platform for target identification for improved rAAV production. To enable screening in a miniaturized format, we first developed a highly sensitive cell-based potency assay that detects the presence of potent AAV9 with vector genomes as low as 2.5E8 vg/mL. We confirmed that our cell-based potency assay shows a strong correlation between capsid ELISA and qPCR-based assay. We used our cell-based potency assay to conduct high-throughput screening of small molecules and transgene over-expression libraries, resulting in the identification of a novel combination of factors that boosted rAAV9 production by over 30-fold in our clonal suspension HEK 293 compared to HEK 293F cells. Current efforts are underway to scale-up these findings to a 50L bioreactor.

1617 Gene Therapy Restores the Transcriptional Program of Fanconi Anemia Hematopoietic Stem Cells

Paula Rio[1,2], Miren Lasaga[3], Amaia Vilas-Zornoza[3], Nuria Planell[4], Susana Navarro[1,2], Marina Ainciburu-Fernandez[3], Daniel Mouzo[4], Asier Ullate-Agote[3], Diego Alignani[3], Josune Zubicaray[5], Jonathan Schwartz[6], Julián Sevilla[5], Felipe Prosper[3,7], David Gómez-Cabrero[4,8,9], Juan A. Bueren[1,2]

[1]Centro de Investigaciones Energéticas, Medioambientales y Tecnológicas (CIEMAT), and Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), Madrid, Spain,[2]Instituto de Investigaciones Sanitarias. Fanconi anemia (FA) is an inherited disorder predominantly associated with bone marrow failure (BMF) and cancer predisposition. We have recently shown that lentiviral-mediated gene therapy in non-conditioned patients can progressively improve peripheral blood cell counts or stabilize these counts when used in early stages of the BMF. Here we have investigated whether defects in the transcriptional program of hematopoietic stem and progenitor cells (HSPCs) from FA patients can be corrected by gene therapy, or on the contrary are irreversible due to the intrinsic characteristics of the disease or because of accumulated DNA damage. To investigate this question, BM samples from four FA-A patients included in the FANCOLEN 1 trial were obtained 2 to 4 years post-gene therapy. $CD34^+$ cells were then purified and analyzed by single-cell RNA seq. Data was preprocessed using Seurat v4, and a machine learning framework was conducted to identify the different HSPC populations. Corrected and uncorrected $CD34^+$ cell populations coexisting in these patients were then classified based on the expression of FANCA. scRNAseq analyses allowed us to identify the presence of $FANCA^+$ and $FANCA^-$ cells within the different HSPC populations present in the BM of gene therapy treated patients. The transcriptional analysis of $FANCA^+$ and $FANCA^-$ cells showed statistically significant changes between these populations which were shared in the different HSPCs and reproducible in the four FA gene therapy treated patients. Furthermore, changes in the transcriptional program between $FANCA^+$ and $FANCA^-$ HSPCs from these FA patients resembled the ones noted when HD HSPCs were compared with $FANCA^-$ HSPCs. Finally, a gene-set enrichment analysis revealed that the genetic correction of FA HSPCs normalized several relevant pathways in FA through the upregulation of genes associated with DNA damage detection and repair, cell cycle, DNA replication, and telomere maintenance. Our results show that lentiviral-mediated gene therapy reprograms the altered HSPC molecular circuits in FA patients. Furthermore, our study reveals that the gene-expression fingerprint of corrected FA HSPCs resembles the transcriptional program of healthy HSPCs. These observations demonstrate for the first time that defects in the transcriptional signature and molecular pathways of FA HSPCs can be restored by means of lentiviral-mediated gene therapy.

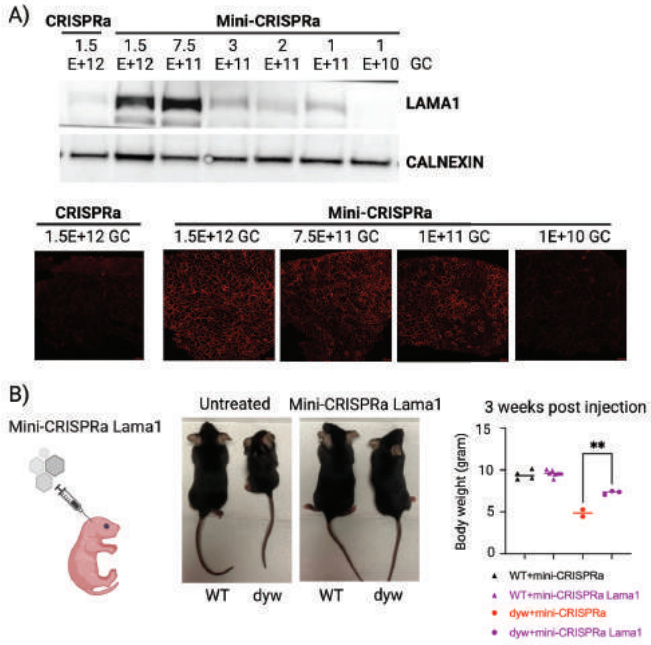
1618 Development of Miniaturized CRISPR Activation for a Single AAV Delivery Method for Muscular Dystrophy

Jia Qi Cheng Zhang, Marie Johnson, Anushe Munir, Yonne K. Tenorio de Menezes, Robert D. Nicholls, Dwi U. Kemaladewi

Pediatrics, University of Pittsburgh, Pittsburgh, PA

LAMA2-related dystrophies (LAMA2-RD) are a subtype of congenital onset muscular dystrophy caused by mutations in the *LAMA2* gene encoding laminin-α2, an extracellular protein essential for skeletal muscle and Schwann cell functions. Diseased correction is hampered by the mutation heterogeneity in patients, for which over 300 disease-associated mutations have been reported. In contrast, the upregulation of the compensatory gene *LAMA1* can serve as a mutation-independent approach applicable to all patients. We previously showed that upregulation of *Lama1* via AAV-mediated CRISPR-activation (CRISPRa) rescues disease phenotypes in mice. However, it required the use of dual-AAVs, which directly contributes to a high dose, toxicity, and cost. In this project, we aim to generate a mini-CRISPRa system suitable for a single AAV9 packaging to improve the clinical relevance of this technology. First, we swapped the commonly-used CMV promoter with a novel, 7.5x-shorter synthetic promoter termed 4xNRF1 to drive *Sa*dCas9 expression. Subsequently, we substituted the previously used 2xVP64 transcriptional activators with a miniaturized tripartite VP64, P65, and RTA activators (miniVPR), and coupled it with a single gRNA targeting the mouse *Lama1* promoter. Evaluation of the mini-CRISPRa system revealed robust *Lama1* upregulation in murine myoblasts. Furthermore, we observed successful *Lama1* upregulation in tibialis anterior muscles of LAMA2-RD mice (termed dyw) at the doses of 1.5E+12 AAV9 GC to 1E+11 GC; the latter dose was 15 times lower than previously reported (Figure A). Subsequently, we treated neonatal dyw mice with the mini-CRISPRa system via temporal vein injection. Compared to the untreated dyw, the treated dyw mice have reduced hindlimb paralysis, improved mobility, and body weight at 3 weeks post-treatment (Figure B). Current experiments involve quantitative analyses of neuromuscular functions, examination of survival, and immune responses upon treatments. Collectively, our data indicate that the mini-CRISPRa system is a more compact, yet more potent CRISPR activation system that shows significant promise in ameliorating the disease phenotypes in LAMA2-RD mice. The approach we developed opens up innovative therapeutic avenues based on the upregulation of compensatory genes that are potentially applicable to other diseases.



1619 Validating Reliability of Genome Editing Using Ion Channels as Drug Target

B. Pattnaik[1], Meha Kabra[2], Pawan Shahi[2], David Gamm[3], David R. Liu[4], Shaoqin S. Gong[3], Krishanu Saha[5]

[1]Pediatrics, Ophthalmology and Visual Sciences, University of Wisconsin, Madison, WI,[2]Pediatrics,, University of Wisconsin, Madison, WI,[3]Ophthalmology and Visual Sciences, University of Wisconsin, Madison, WI,[4]Harvard University and HHMI, Cambridge, MA,[5]Biomedical Engineering, University of Wisconsin, Madison, WI

Severe forms of inherited ocular channelopathy are caused by point mutations in *KCNJ13,* which affect the retinal pigment epithelial (RPE). We have previously demonstrated that both gene therapy and translational read-through result in functional recovery as tested using induced pluripotent stem cells iPSC-RPE from a patient line. AAV-gene therapy related immune responses, CRISPR/Cas9 gene editing associated off-targets, and indels pose some challenges in drug discovery and its clinical translation. We used Adenosine and Cytosine base editors (ABE8e, evoCDA-CBE & BE4max-CBE) along with a specific sgRNA as proof-of-concept correction of *KCNJ13* point mutations (c.158G>A [p.W53X] and c.431T> C [p.L144P]) using nanoparticle-mediated delivery to HEK293-stable cells, LCA16-patient's specific fibroblasts and iPSC-RPE. BE efficiency, protein localization and high throughput channel function were assessed in edited cells and compared with non-edited mutant and WT cells. Potential off-targets were screened to evaluate the accuracy and efficacy of BEs. CBE for L144P editing in stable cells resulted in high on-target editing (60-80%). However, bystander 'Cs' in the protospacer region led to either missense (~61%) or silent (~59%) variations in edited cells which affected the gene function. Very few reads had a WT gene sequence (~3%). ABE8e mRNA for W53X correction in stable cells showed 50% editing. Nanoparticle-mediated delivery of ABE8e in fibroblasts (47% editing) and iPSC-RPE (20%) established its use for *in vivo* BE delivery. On target indel mutagenesis (<3%) and screening of potential off-target sites (<1%) indicated high accuracy of the ABEs. Electrophysiology assays demonstrated in vivo functional rescue in a mouse model. **In conclusion,** sequence complexity of L144P locus poses some challenges to edit it with the current generation of CRISPR BEs. Using modified CBEs with tighter editing windows or using prime editing for the hard-to-rescue alleles would be beneficial. Functional studies to confirm the therapeutic potential of base editing is must. A caution is warranted to avoid detrimental outcomes of silent editing. W53X editing using ABE8e delivered via non-viral platform, silica nanoparticles showed specific editing without generating detrimental bystander substitutions, indels or off-target edits elsewhere in the genome. K^+ conductance in iPSC-RPE confirmed the functional rescue of the Kir7.1 channel following base editing. Altogether, these preclinical base editing studies for correcting mutations causing childhood blindness and other ocular genetic diseases hold promise for clinical translation.

1620 Optimizing Plasmid Complexation Parameters to Streamline AAV Vector Manufacturing

Ngan Trinh, Kelly Geosits, Khan Umaer, Paul Kroeger, Marguerite Campbell, Srivanya Tummala, Brian Tomkowicz

Viral Vector Research & Development, Center for Breakthrough Medicines, King Of Prussia, PA

Transient transfection of three plasmids (rep, cap, and helper) in HEK293 cells facilitated by a transfection reagent is the most widely used method for AAV and other viral vector production. It has, in fact, been shown effective for all AAV serotypes and is a regulatory-validated approach. Transfection reagents are necessary for transient transfection because naked DNA is not readily transported across cell membranes. The mixture of plasmid DNA with transfection reagent, or complexes, tend to be unstable and shear-sensitive, limiting the stirring speed for mixing, the rate at which they can be transferred from the mixing tank to the bioreactor, and the time they remain available for transfection into HEK293 cells. Optimization of the complexation processes is therefore essential to ensuring the efficiency and productivity of the overall transient transfection process leading to higher yield of viral vectors. The three main parameters that significantly impact the complexation process include: 1. The choice of complexation reagent, 2. ratio of transfection reagent to plasmid DNA, and 3. complexation time. Perturbations of these factors influence the size of the complexes generated, which has been linked to transfection efficiency across cellular membranes. Selection of the appropriate transfection reagent for use in recombinant viral vector production can directly impact the efficiency of the complexation step and ultimately the productivity during the transfection process. Reagents based on lipofectamine, polyethyleimine (PEI) and lipid-polymer complexes are now available. PEIPro® (Polyplus) has been widely used and is suitable for use with many virus types on both adherent and suspension cell culture platforms. FectorVIR® AAV (Polyplus) is a reagent designed specifically for suspension-based transient transfection of AAV vectors and is experiencing increasing use as the industry transitions to larger bioreactor processes. Both reagents are available in research and GMP grades, facilitating tech transfer from the lab to commercial

scale. FuGENE® HD and 4K (Promega Corporation) are additional multicomponent (cationic lipid polymer) transfection reagents for research-scale transient transfection in various mammalian cells (including both HEK293 and Chinese hamster ovary, or CHO) with GMP-readiness expected this year. To obtain a greater understanding of how the complexation process impacts down-stream yields of AAV, complexation reactions were performed over a range of time and reagent ratios using plasmids typically used in triple-transfection method for AAV generation. Down-stream purification using AKTA-based affinity and anion-exchange chromatography, coupled to analytical characterization of purified AAV vectors were performed. Herein we present how selection of these reagents directly impacts virus yield and recovery.

1621 Novel Buffer Formulations for Improved Recombinant Lentiviral Vector Stability and *In Vivo* Delivery to the Murine Lungs

Kamran M. Miah[1], Mario Chan[2], Uta Griesenbach[3], Eric W.F.W. Alton[4], Stephen C. Hyde[5], Deborah R. Gill[5]

[1]Gene Medicine Group, Nuffield Department of Clinical and Laboratory Sciences, University of Oxford, Oxford, United Kingdom,[2]National Heart and Lung Institute, London, United Kingdom,[3]Imperial College Faculty of Medicine, London, United Kingdom,[4]Imperial College London, London, United Kingdom,[5]University of Oxford, Oxford, United Kingdom

We have developed lentiviral vectors (LVs) based on recombinant Simian Immunodeficiency Virus pseudotyped with the Sendai Virus Fusion and Hemagglutinin-Neuraminidase glycoproteins (rSIV.F/HN). This vector platform has high *in vivo* gene transfer potency for the respiratory tract and directs sustained, high-level transgene expression after both single and repeated administration. We are developing rSIV.F/HN vectors for a range of acquired and inherited respiratory disorders. In our research-grade manufacturing process, rSIV.F/HN vectors are formulated via tangential-flow filtration (TFF) buffer exchange. In our cGMP-grade manufacturing process TFF is utilised in both the drug substance (DS) and drug product (DP) steps, both of which include a terminal hold at -80°C. Thus, the ideal vector formulation would provide protection from both TFF-induced shear and freeze/thaw steps. Our research-grade vectors have historically been formulated in TSSM buffer, composed of 20mM Tris pH7.3, 100mM NaCl, 10mg/mL sucrose, 10mg/mL mannitol, all reagents Generally Regarded As Safe (GRAS) by the FDA, and offers some freeze/thaw and shear force protection. In this study, we prepared rSIV.F/HN vectors in two new, proprietory formulation buffers (Buffer B and C, each generated with GRAS reagents) and compared their performance with vectors formulated in TSSM. We found that all three formulation buffers supported 3 freeze-thaw cycles with little or no loss of vector transduction (p>0.57). We also noted, however, a trend for a modest loss of vector activity as the number of freeze-thaw cycles was increased from 5 to 10 suggesting that additional formulation development may be necessary if further enhanced freeze/thaw stability is desirable. Dynamic light scattering studies suggested that TSSM and Buffer B imparted similar Zeta potential and particle size on our vectors, suggesting that colloidal stability would be similar. Encouragingly, we noted that extended holds (up to 7 days) at 4°C were possible in both TSSM and Buffer B without loss of vector transduction activity (p>0.99). This property may allow the removal of the -80°C hold between our DS and DP steps and simplify our manufacturing process. Interestingly, while TSSM and Buffer B supported brief (2h) excursions to 37°C with little or no loss of vector activity (p>0.33), vector formulated in Buffer C tended to show a modest loss of transduction activity. Nebulisation of the product is desirable for delivery to the lungs and, therefore, we evaluated vector transduction after passage through an Aerogen Solo vibrating mesh nebuliser. Encouragingly, vector formulated in both TSSM and Buffer B were largely unaffected by nebulisation (retaining 94.5% and 89.4% of their non-nebulised activity). To assess *in vivo* performance, we delivered matched quantities of rSIV.F/HN vectors expressing firefly luciferase formulated in TSSM and Buffer B to the lungs of BALB/c mice. Both formulations directed abundant lung transgene expression at indistinguishable levels (p=0.34). In summary, we have generated two new formulation buffers for LVs, one of which (Buffer B) supports multiple freeze-thaw events, extended holds at 4°C, and 37°C thermal challenge in a manner indistinguishable from the TSSM benchmark. Furthermore, vector formulated in Buffer B retained a high degree of transduction activity after nebulisation and directed abundant *in vivo* gene transfer. Thus, we find that Buffer B formulated rSIV.F/HN vectors warrant further investigation to establish their suitability for clinical development.

1622 Pentose Alcohol Metabolite Alters Gene Expression and Dystroglycan Glycosylation in a KRAS-Dependent Manner

Jason D. Tucker[1], Pei Lu[2], Ravi Doddapaneni[1], Anthony Blaeser[3], Qi Lu[4]

[1]McColl-Lockwood Laboratory for Muscular Dystrophy Research, Atrium Health, Charlotte, NC,[2]Carolinas Medical Center, Charlotte, NC,[3]Carolinas Healthcare System, Charlotte, NC,[4]Atrium Health, Charlotte, NC

The protein α-Dystroglycan, and its post-translational O-glycosylation (matriglycan) enables its critical function in binding the muscle extracellular matrix. Without matriglycan, the functional capacity of dystroglycan as part of the dystrophin-associated protein complex is lost, and leads to pathologies known as the dystroglycanopathies. We have recently shown that the metabolite ribitol, a pentose alcohol, is able to upregulate functional glycosylation of α-dystroglycan in FKRP-mutant mouse models of Limb Girdle Muscular Dystrophy, and in breast cancer epithelial cells. We have also demonstrated that the effect of ribitol administration results in altered gene expression. Analyzing gene expression profiling, we have identified a number of candidate genes altered with administration of ribitol and found that the Kirsten Rat Sarcoma protooncogene (KRAS) may play a significant role in the glycosylation of α-dystroglycan. Using siRNA, we have found that suppression/knockdown of KRAS expression in the MCF-7 breast cancer cell line results in decreased expression of matriglycan-modified dystroglycan. Interestingly, this reduction in matriglycan-modified α-dystroglycan cannot be rescued by ribitol supplementation. The highly ordered process of O-mannoglycosylation of α-dystroglycan has been well characterized through the examination of the functional roles of more than 18 glycosyltransferase enzymes involved. However, it is not clear how expression of these genes is regulated in relation to cell proliferation, differentiation, and cellular functions. The ability of a single gene such as KRAS, however, to modulate detectable

matriglycan glycosylation of α-DG is unique and warrants further study for understanding of this process and for potential therapeutic applications for both the oncologic and dystrophy fields.

1623 Multiple *In Vitro* Differentiated Skeletal Muscle Models for Screening of Synthetic Muscle Promoters for Gene Therapy

Dustin Lee, Enrico Mossotto, Josefa M. Sullivan, Natalia Fabela, Edgar Hernandez, Matthew J. During, Alexandria Forbes, Ce Feng Liu

Molecular & Protein Engineering, MeiraGTx LLC, New York, NY

Gene therapy delivery to skeletal muscle for inherited musculoskeletal disorders has been challenging, in part due to the target tissue's large size, mass, and anatomical distribution, and the requirement for high systemic vector doses of adeno-associated virus (AAV) for therapeutic efficacy. High AAV doses have caused dose-limiting toxicity and immunogenic responses, as observed in ongoing clinical trials for inherited muscular dystrophies. Muscle tissue is also an effective target for the therapeutic production of secretory proteins, like enzymes, hormones, antibodies, and clotting factors, following local delivery of the viral vector containing the therapeutic transgene to the muscle. The potential of the muscle as a target for gene therapy highlights a demand for more potent, tissue-specific, and compact regulators of therapeutic gene expression, such as promoters. Stronger promoters can provide therapeutic potency at lower viral vector doses, while a reduction in size allows for more efficient packaging of larger transgenes or expression cassettes. To our knowledge, there is a lack of accessible data comparing transcriptomic profiles across multiple *in vitro* and *in vivo* skeletal muscle models pre- and post-differentiation, which can be used for designing and testing novel muscle-specific AAV therapies. Here, we present multiple *in vitro* differentiated myotube models of skeletal muscle for more efficient evaluation of engineered muscle promoters for gene therapy and their characterization by transcriptomics and immunofluorescence analyses. The differentiation-induced myotube models include C2C12 immortalized mouse myoblast cell lines, primary human myoblasts from the quadriceps, and human induced pluripotent stem cell-derived myoblasts. Transcriptomic changes were assessed before and after differentiation for each model and condition. After validating the presence of key myotube differentiation markers, a set of in-house proprietary muscle promoters were tested in these models and compared against known reference muscle promoters currently used in clinical trials of AAV-delivered treatment for muscular dystrophies. Top performing candidates from our rationally designed compact muscle-based promoters were evaluated in these *in vitro* skeletal muscle models, in addition to *in vivo* assessment in C57BL6 mice, with our results showing higher transgene expression compared to reference muscle promoters. In summary, we show promising reliable *in vitro* differentiated skeletal muscle models characterized via RNAseq and immunofluorescence as well as demonstrate the potential of our promoter engineering platform designed to target specific tissues of interest, like skeletal muscle

1624 A High-Fidelity RNA-Targeting Cas13 Restores Paternal Ube3a Expression and Improves Motor Functions in Angelman Syndrome Mice

Jinhui Li[1], Yuan Ma[1], Linyu Shi[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Angelman Syndrome (AS) is a severe neurodevelopmental disorder, with an incidence of approximately 1/12000-1/20000 worldwide, which is characterized by seizures and severely impaired motor, cognitive, and language skills. AS is mainly attributable to loss of maternally inherited *ubiquitin protein ligase E3A* (*UBE3A*), which mediates the targeted degradation of several protein substrates. Only the maternally inherited UBE3A allele in neurons is active due to selective silencing of paternal *UBE3A* by its antisense transcript, *UBE3A-ATS*. **Methods:** We tested the knockdown efficiency of Ube3a-ATS in primary neurons isolated from AS mouse (Ube3am−/p+) using lentivirus packaged high-fidelity Cas13 (hfCas13x.1) and a crRNA (Fig. 1B). To evaluate the efficiency of Ube3a-ATS silencing in brain, AAV with hfCas13x.1/cr9 was injected into postnatal day 0-1 AS mice via intracerebroventricular (ICV) injection. The protein of reinstated UBE3A in dissected brain regions was evaluated by western blot (Fig. 1C, D). The body weight and behavioral tests were evaluated in AS mice with AAV-hfCas13x.1/cr9 (Fig. 1E-H). **Results:** We isolated and infected AS (*Ube3a*$^{m-/p+}$) primary cortical neurons with lentivirus expressing Cas13x.1-Flag and found that the UBE3A expression restored by hfCas13x.1/cr9 was enriched in the nucleus of AS mouse primary neurons (Fig. 1B). To evaluate the efficiency of Ube3a-ATS silencing in brain, we injected AAV-hfCas13x.1/cr9 into neonatal AS mice and observed that paternal UBE3A protein expression reached 35.9% in cortex and 41.6% in hippocampus of AS mice at 4 weeks post infection with AAV-hfCas13x.1/cr9 (Fig. 1C, D), compared with that in WT mice. We analyzed these results of the two genders separately. Obesity in female AS mice treated with hfCas13x.1/cr9 was significantly relieved (Fig. 1E), while male AS mice only showed slight trend of improvement, indicating a sex-specific effect, which was also observed in a previous study using SaCas9 to treat AS. In addition, AS mice treated with hfCas13x.1/cr9 also showed improvement in dowel test (Fig. 1G) and beam walking test (Fig. 1H). **Conclusions:** We demonstrated that RNA targeting of paternal Ube3a-ATS with the high-fidelity CRISPR-hfCas13x.1 system (Fig. 1A) could significantly restore Ube3a expression in the cultured mouse neurons and *in vivo*, reduce obesity and improve several behavioral deficits in AS mice, providing a potential and promising therapeutic strategy for patients with AS.

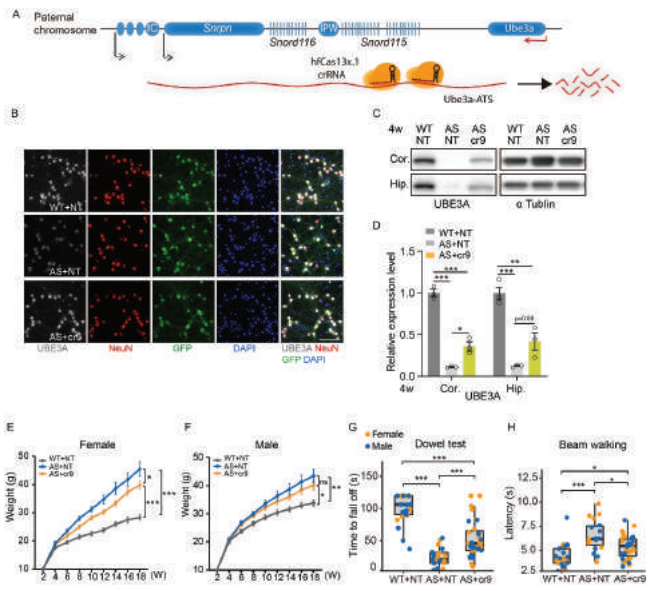


Fig. 1. The treatment effect of AAV-hfCas13X/cr9 in AS mice. A, Schematic diagram of the Ube3a locus in the mouse genome. **B**, Immunofluorescence staining for indicated proteins in lentivirus-infected primary neurons of AS mice. Primary neurons of WT or AS mice were infected with lentivirus containing hfCas13x.1/U6-NT or hfCas13x.1/U6-cr9. **C, D**, Western blot (**C**) and quantification (**D**) of protein expression in the cerebral cortex (cor.) and hippocampus (hip.) of WT and AS mice with indicated treatment at 4 weeks. **E, F**, Body weight. **G, H**, Dowel test and beam walking data in mice with indicated treatment.

1625 Deciphering the Mechanism of Nuclease-Free Homologous Recombination Based Genome Editing

Lakshmi V. Bugga[1], Venkatesh Sivanandam[2], Esther Rodriguez[2], Ka Ming Pang[2], Saswati Chatterjee[3]

[1]Surgery, City of Hope, Duarte, CA,[2]City of Hope, Duarte, CA,[3]Beckman Research Institute of City of Hope, Duarte, CA

The replication-defective, non-pathogenic, adeno-associated viruses (AAVs) have gained in prominence for their therapeutic potential in genetic medicine. One unique property of AAV is their exclusive ability to mediate homologous recombination (HR) in the absence of exogenous nucleases. The stem cell-derived AAVHSCs in particular have a propensity to mediate precise and efficient HR with high on-target accuracy at significantly higher efficiencies than other AAV serotypes. The editing outcomes achieved by AAVHSC are precise without accompanying indel mutations or insertion of viral sequences, including ITRs at the edited genomic loci. In addition, the absence of a requirement for prior nuclease-mediated cleavage preserves genome-wide integrity. Notably, AAVHSC editing occurs efficiently in vivo in post-mitotic cells and tissues. In addition, AAV has the clear advantage of a built-in delivery mechanism. Importantly, the significantly higher in vivo and in vitro editing efficiencies displayed by AAVHSC editing vectors enables therapeutic translation. We have previously shown that the presence of functional BRCA2 is obligatory for successful AAVHSC-mediated HR. Other absolute requirements for effective AAVHSC genome editing include use of single stranded editing genomes which are bounded at the 5' and 3' ends by the palindromic self-complementary inverted terminal repeats (ITRs) which self-base pair to form T or U-shaped structures. In addition, the single-stranded AAV genomes must encode homologous sequences complementary to the target chromosomal loci to be edited. However, little is known about the exact mechanisms involved. To delineate the mechanism of AAV-mediated HR, we hypothesized that the transition between the single-stranded AAV editing genomes and the self-complementary palindromic AAV ITRs forms a unique structure that resembles a stalled replication fork. This junction is then recognized by proteins of the HR complex which localize to the transition site on the AAV editing genome. This in turn leads to the onset of HR. To test this hypothesis, we evaluated the direct interaction of cellular HR proteins with the AAVHSC editing genome. Primary human cells were transduced with packaged and purified AAVHSC editing vectors. Intranuclear AAVHSC editing genomes were then analyzed for their interaction with a panel of HR-associated and DNA repair proteins by chromatin immunoprecipitation (ChIP) analyses at different time points post-transduction. ChIP analyses revealed the preferential localization of HR proteins including BRCA2, Rad51 and Rad52 to the AAV editing genomes. Further mapping demonstrated that binding of BRCA2 in particular occurred near the ITRs. Electrophoretic mobility shift analyses were then performed to independently confirm the ChIP data. Results showed specific binding of BRCA2, Rad51 and Rad 52 to AAV ITRs. In conclusion, our results demonstrated that transduction with AAVHSC editing vectors specifically and preferentially recruited cellular HR proteins, including BRCA2 to the single stranded AAV editing genomes which then led to the onset of HR.

1626 Effects of Transgene Size on Self-Complementary rAAV Vectors

Amanda U. Ibe-Enwo

Voyager Therapeutics, Inc., Lexington, MA

Recombinant adeno-associated virus (rAAV) vectors are a promising tool for gene therapy due to their ability to efficiently and stably deliver genetic material to target cells. rAAV genomes can be packaged either in single-stranded DNA format (ssAAV) or a double-stranded, self-complementary DNA format (scAAV). Due to circumvention of the second-strand synthesis step required for transgene expression, scAAV vectors typically support higher and faster expression compared to ssAAV vectors. However, this enhanced expression comes at the cost of a reduced genome capacity (approximately 2.3 kb ssDNA vs 4.7 kb ssDNA for ssAAV designs). Manufacture of rAAV vectors at the scale required for addressing patient need remains a significant challenge. The baculovirus-infected Sf9 insect cell system is an attractive option to address the problem of scalability. However, the impact of transgene size for rAAV genomes has not been explored in the context of this system. We therefore sought to investigate the effect of transgene size on the functionality and physical characteristics of scAAV vectors produced in both HEK293-plasmid and Sf9-baculovirus systems. We constructed scAAV vectors of different sizes ranging from 2.7 kb to 5.4 kb ssDNA and produced these vectors in both the Sf9-baculovirus and HEK293 triple-plasmid transfection system. We characterized these vector preparations for productivity, vector genome heterogeneity, and transduction efficiency. Our results suggest that transgene size moderately impacts productivity of the vector in HEK293-plasmid systems but not in the Sf9-baculovirus system. Furthermore, we observed that the size of the transgene also affected vector genome heterogeneity in a production system-specific manner. As transgene size increased, the single predominant band was lost at a smaller threshold in Sf9-baculovirus compared to HEK293. In conclusion, our study demonstrates that transgene size of scAAV vectors affect

transduction efficiency, and this impact is dependent on expression system used to generate the vector. These findings have important implications for the development of scAAV vectors for gene therapy applications, as the size of the transgene must be carefully considered to ensure optimal vector performance. Future studies are being done to identify the optimal transgene size that would enable manufacturing of high-quality scAAV vectors.

1627 Integrated Purification Process Development Strategy to Enable Robust and Scalable Manufacturing of AAV

Mi Jin, Ohnmar Khanal, Vijesh Kumar, Matthew G. Petroff, Lu Wang

Technical Development, Downstream and Drug Product Development, Spark Therapeutics, Philadelphia, PA

Recombinant adeno-associated virus (rAAV) based vector is the most prominent modality used in in vivo gene therapy, due to its favorable profile in safety, efficacy, and durability. However, the manufacturing of rAAV vectors remains limiting. Rapid process development cycles that lead to robust and scalable manufacturing process is a prerequisite, to enable fast to clinic and reliable supply with consistent product quality for commercialization. Current challenges in downstream manufacturing process design include 1. processing bottle neck created by large volume low titer bioreactor harvest 2. low percentages of fully packaged vectors and often highly complex compositions of empty and partial capsids in feed stream 3. product and process related impurities 4. heightened regulatory expectations on viral clearance 5. scale up and scale down differences that may impact product quality and productivity 6. high production cost 7. limited material supply for process development. Several approaches can help address above challenges: 1. Reconfigure equipment to enable aggressive scale-down to micro-scale for process development. 2. Select high throughput, quick turnaround assays for efficient development cycle. 3. Leverage mechanistic modeling and process modeling to gain process understanding. 4. Employ high throughput automation and Design of Experiment (DoE) to enable process robustness evaluation. 5. Understand scale up differences that can present product quality or yield impact, and mitigate risks through targeted manufacturing equipment testing or pilot studies. We will present a comprehensive process development and process characterization strategy, with case studies demonstrating how to overcome key downstream purification challenges, particularly in empty, partial, and full capsid separation. We will also highlight areas of opportunity to enable future high efficiency AAV purification platform in anticipation of significant upstream viral vector production enhancement.

1628 Cryptic Splice Products in *PSEN2* Represent Novel Therapeutic Targets for Alzheimer's Disease

Meredith Course[1,2], Jenna Somberg[1], Kathryn Gudsnuk[1], Daniel D. Child[1], Caitlin S. Latimer[3], Brian C. Kraemer[4], C. Dirk Keene[3], Thomas D. Bird[1,4], Suman Jayadev[1], Nicole F. Liachko[4], Paul N. Valdmanis[1]

[1]Medicine (Medical Genetics), University of Washington, Seattle, WA,[2]Colorado College, Colorado Springs, CO,[3]Laboratory Medicine and Pathology, University of Washington, Seattle, WA,[4]Geriatrics Research Education and Clinical Center, Puget Sound VA Medical Center, Seattle, WA

Pathogenic variants in *APP*, *PSEN1* and *PSEN2* can cause early-onset familial Alzheimer's disease (AD). The molecular events leading to AD in individuals with late-onset sporadic AD are still unclear even though they share the same clinical and pathological features of AD. Using targeted PacBio long read isoform sequencing (Iso-Seq), we recently reported the characterization of tens of thousands of complete *PSEN1* and *PSEN2* transcripts in the prefrontal cortex of individuals with sporadic AD, familial AD (carrying *PSEN1* and *PSEN2* pathogenic variants), and controls. Surprisingly, we found several alternative splicing differences in *PSEN2* that are significantly elevated in sporadic AD including inclusion of a human-specific cryptic exon present in intron 9 of *PSEN2* (termed exon 9B) present in 11.8% of full-length reads in sporadic AD samples relative to 1.9% of controls ($p = 0.002$) and 3.4% of *PSEN* variant carriers ($p = 0.005$) as well as a 77bp intron retention product prior to exon 6. These *PSEN2* splice products are predicted to generate a prematurely truncated PSEN2 protein and were confirmed in an independent RNA-seq dataset of ~80 AD cases and ~80 controls from cerebellum tissue (Course et al., Brain 2022). To extend these findings we analyzed *PSEN2* exon 9B isoform levels in additional brain regions. We found exon 9B was significantly elevated in sporadic AD relative to controls in the parietal lobe ($p = 0.02$) as well as the temporal lobe ($p = <0.001$). However, levels of exon 9B were independent of pathology associated with the RNA binding proteins TDP-43 or MSUT2. We are testing functional effects of exon 9B inclusion in Aβ production and PSEN2 protein levels and utilizing antisense oligonucleotide approaches to target these aberrant isoforms. Collectively, our findings expand our understanding of *PSEN2* splice variants in the development of late-onset sporadic AD thereby revealing novel potential therapeutic strategies for AD.

1629 Gene Therapy Development for DDX3X Syndrome

Andrea Boitnott, Xin Chen, Steven J. Gray

UT Southwestern Medical Center, Dallas, TX

DDX3X syndrome is a neurodevelopmental disorder first described in 2015 and today is thought to be one of the leading known genetic causes of intellectual disability in females. The syndrome is caused by mutations in the Dead-Box Helicase 3 X-Linked gene (*DDX3X*), an abundant and ubiquitously expressed RNA helicase. Despite the clinical burden of DDX3X syndrome and the known genetic cause, no study to date has determined whether gene-based therapies would be an effective treatment for these patients. Our hypothesis is that DDX3X gene reinstatement, after altered DDX3X function during prenatal development, will restore proper protein function and, therefore,

ameliorate disease symptoms preclinically in a timepoint dependent manner that is sensitive to the level of DDX3X. To initially determine preclinically if gene replacement therapy for DDX3X syndrome is beneficial, we have developed an AAV9 gene therapy carrying a functional copy of *DDX3X* and are testing its safety and efficacy in mice. The mouse model used in our study is a previously characterized haploinsufficient *Ddx3x* (*Ddx3x*$^{+/-}$) mouse with construct and face validity for DDX3X syndrome. *Ddx3x*$^{+/-}$ females and *Ddx3x*$^{flox/+}$ control female littermates were injected at postnatal day (P) 1 via a bilateral intracerebroventricular injection with vehicle or AAV9-DDX3X at a low or high dose. To determine efficacy and safety, the mice are assessed behaviorally for 1 year. Developmental milestones, spanning physical, sensory, and motor domains are assessed from P2-20. Anxiety, EEG spike trains, and sleep behavior are assessed at 3-4 months of age. Anxiety and motor function is assessed at 12 months, followed by a full necropsy for histological studies. *Ddx3x*$^{+/-}$ females treated with low and high dose AAV9 have a trend towards less falls on a negative geotaxis paradigm compared to *Ddx3x*$^{+/-}$ females treated with vehicle in the first 3 weeks of life, but no other benefit was noted from the P2-20 developmental assessments. *Ddx3x*$^{flox/+}$ control female littermates treated with low or high dose AAV9 do not show any behavioral toxicity compared to *Ddx3x*$^{flox/+}$ females treated with vehicle on these developmental milestones. *Ddx3x*$^{+/-}$ females treated with high dose, but not low dose, have significantly reduced anxiety compared to *Ddx3x*$^{+/-}$ females treated with vehicle at 3 months, suggesting that there is a threshold for the amount of DDX3X needed for therapeutic benefit. However, *Ddx3x*$^{flox/+}$ control female littermates treated with high dose AAV9 have increased anxiety, suggesting that overexpressing DDX3X to this level can cause behavioral changes. Sustained anxiety behavior changes will be assessed at 12 months. Our results indicate that the dosage of DDX3X is important for behavior, where not enough or too much may lead to altered behavior. Determining the optimal amount of DDX3X expression for normal development and function will be assessed in future work and help guide designing the proper gene therapy vector to treat DDX3X syndrome.

1630 A New Method to Design Lineage Specific Promoters Enables Innovative Immunotherapy Approach Using CAR in Hematopoietic Stem Cells

Clara Soulard[1,2], Aissa Benyoucef[1], Yuanyi Li[1], Khampoun Sayasith[1], Marion Dubuissez[1], Panojot Bifsha[1], Aurélien Colamartino[1], Inès Ben Fadhel[1], Kathie Beland[1], Elie Haddad[1,2]

[1]CHU Sainte-Justine Research Center, Montréal, QC, Canada,[2]University of Montréal, Montréal, QC, Canada

The growing fields of stem-cell-derived therapy for cell and gene therapy are currently facing an important bottleneck: the impossibility to target the expression of a gene into a given cell or tissue when a gene is modified in stem cells. This bottleneck currently prevents the possibility of using modified stem cells in many therapeutic situations. There is a need for tools to induce targeted gene expression in selected cells, both in terms of localization (tissue) and timing (stage of differentiation). To overcome the issue, we have developed a bioinformatic pipeline to identify key non-coding regions of the genome that have enhancer properties and can act as progeny or lineage-specific promoters when coupled with minimal promoter elements. To demonstrate the versatility of our *in silico* method we have applied it to both hematopoietic lineages, by designing T and/or NK-specific synthetic promoters, and non-hematopoietic lineages by generating muscle-specific promoter. Synthetic promoter specificity was validated using either hematopoietic stem cells (HSCs) or induced pluripotent stem cells (IPSCs) transduced with lentiviral vectors coding Green Fluorescent Protein (GFP) reporter gene under synthetic promoters. Modified HSCs were differentiated *in vitro*, using an organoid thymic differentiation system, into T cells, NK cells and B cells. Lead candidates were confirmed *in vivo* in the Bone Marrow Liver Thymus (BLT) humanized mouse model. Both *in vitro* and *in vivo*, GFP expression was observed only in T and NK subpopulations after HSC transduction with a T/NK-specific promoter. Modified IPSCs were differentiated into the three primary germ layers (mesoderm, endoderm and ectoderm) and then into neurons, hepatocytes and muscle lineages. Flow cytometry and immunofluorescence results showed that our muscle-specific promoter induced GFP expression only in mature terminally differentiated myotubes. GFP expression was observed neither in muscle cell progenitors, nor in earlier stages of differentiation or in neural or hepatic lineages. To demonstrate the potential of our synthetic promoter design platform, we used our technology to develop HSC-based chimeric antigen receptor (CAR) therapy for the treatment of refractory cancer. Despite the high efficacy of CAR-T therapy, many patients do not respond or will relapse after an initial response, in part due to low *in vivo* persistence of engineered T cells, poor proliferation and T-cell exhaustion. To address these issues, we explored an alternative therapeutic approach in which CAR transduction is made in HSCs, instead of T cells, allowing a continuous and progressive replenishment of CAR-modified cells. Constitutive expression of a CAR in the whole hematopoietic compartment highly increases the risk of disrupting cell differentiation process and activating a proto-oncogene. We showed in the BLT humanized mice that high level of CAR expression on T cell progenitors strongly impair T cell development. HSCs engineered with a CAR under human elongation factor-1 (EF1)-α constitutive promoter failed in differentiating into mature T cells. By substituting the EF1-α promoter for our synthetic T/NK-bispecific promoter in the CAR cassette, we overcome *in vitro* CAR-T cell differentiation blocking and generate simple positive mature CD4 and CD8 CAR-T cells derived from CAR-engineered HSCs. Demonstrating the validity and the functionality of our specific promoters represents a major advance in stem-cell-derived therapy, and an example of a promotor design method that could be applicable to many other fundamental and applicated research fields.

1631 Gene Therapy Mediated Transdifferentiation of Astrocytes to Neurons for the Treatment of Parkinson's Disease

Patty Biezonski[1], Jinlin Su[2], Xinde Hu[2]

[1]Genemagic Biosciences, Wallingford, PA,[2]Genemagic Biosciences, Shanghai, China

In situ cell reprogramming offers the hope of a regenerative therapeutic approach to numerous neurodegenerative diseases. Using AAVs to deliver reprogramming factors to glial cells can result in the transdifferentiation of these cells into neurons and the replenishment

of specific neuronal cell populations lost in a given disorder. Parkinson's disease (PD) results in the loss of dopaminergic neurons in the substantia nigra and decreased dopamine content within the striatum. While gene therapies for monogenetic forms of PD are in development, these do not address the unmet need of the majority of patients whose PD is idiopathic. *In situ* cell programming offers a gene-agnostic approach to address the large patient population without a known genetic cause. Our investigational therapeutic is an AAV vector encoding a reprogramming factor under the control of a glia-specific promoter. In a chemically induced mouse model of PD, treatment with this AAV led to the transdifferentiation of glial cells into electrophysiologically active neurons that express markers of mature dopamine neurons and are capable of taking up and releasing dopamine. Further, this treatment alleviated multiple motor defects common in this PD mouse model. In a chemically induced non-human primate model of PD, treatment with our investigational therapeutic led to improved motor behavior, increased dopamine concentration in the CSF, and enhanced dopamine signal within the striatum as measured by PET-CT. These effects were persistent out to at least one-year post-treatment. These animals continue to be observed two and a half years post-administration, and additional data are expected. Together, these findings support the promising therapeutic potential of *in situ* cell reprogramming for PD and set the stage for testing this novel therapeutic approach in a broad range of neurodegenerative conditions.

1632 Awake Intracerebroventricular Delivery and Safety Assessment of Oligonucleotides in a Large Animal Model

Hector Ribeiro Benatti[1], Rachel D. Prestigiacomo[1], Toloo Taghian[1], Robert King[2], Ugur Celik[3], Elizabeth Parsley[4], Miguel Sena-Estevez[5], Heather L. Gray-Edwards[1]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Department of Radiology, UMass Chan Medical School, Worcester, MA,[3]Center for Clinical Research, UMass Chan Medical School, Worcester, MA,[4]Tufts University Cummings School of Veterinary Medicine, North Grafton, MA,[5]Neurology, UMass Chan Medical School, Worcester, MA

Background: Oligonucleotide therapeutics, including small inhibitory RNAs (siRNAs) or antisense oligonucleotides (ASOs) offer promise in the treatment of several neurological conditions by knocking down expression of toxic proteins and enhancing expression of loss of function proteins (ex. splicing mutations). This class of therapeutics offers great promise in the treatment of previously untreatable disorders; however, they carry a well-established dose related acute toxicity (generalized and myoclonic seizures) at the time of administration. These seizures are hypothesized to be due to chelation of cations by oligonucleotides in the extracellular fluid, thereby lowering the resting membrane potential. Formulation of these compounds in cations has been postulated to prevent the acute toxicity, but a sensitive and quantitative way to track vacant or minor seizure activity in formulation development is lacking. For this reason, we developed a method to track seizure activity in awake animals during and for 24-hours after injection. **Methods:** Here we describe a new surgical technique for intracerebroventricular (ICV) delivery of neurotherapeutics. A catheter was placed into the lateral ventricle of sheep using a combination of pre-operative MRI- and post operative based neuronavigation. The catheter was fixed utilizing a 3D printed anchor system consisting of plastic and ceramic parts (Fig 1). The catheter is then connected to an MRI-safe reservoir with the incision closed over the apparatus. Days to weeks later, a wireless Holter electroencephalography (EEG) is used to measure brain activity and seizure activity is recorded (TrackIt System). The oligonucleotide is the injected under dexmedetomidine sedation and immediately reversed after for EEG recordings after which the animal is returned to its pen with electrodes in place and monitored by EEG and video for the next 24 hours. **Results:** Our surgical technique has reliably fixed the ICV catheter in place in sheep allowed normal outdoor activity for the duration of the study. We are reliably able to detect gamma, beta alpha theta and delta waves for a 24-hour period. EEG abnormalities associated with oligonucleotide administration and prevention with formulation is detectable by EEG in a dose dependent manner. The changes in waveform correlate with alterations in animal behavior phenotypes. Spectral quantification of EEG is underway.

1633 Endosomal Escape Vehicle-Oligonucleotide Conjugates for the Targeted Upregulation and Downregulation of Gene Expression

Ziqing Leo Qian, Xiang Li, Xiulong Shen, Mahboubeh Kheirabadi, Amy N. Hicks, Mark Wysk, Haoming Liu, Ajay Kumar, Nelsa L. Estrella, Patrick G. Dougherty, Suresh Peddigari, Anushree Pathak, Kimberli J. Kamer, Wenlong Lian, Nanjun Liu, Matthew Streeter, Sara L. Blake, Christopher M. Brennan, Ning Li, Vlad Batagui, Keyede Oye, Ningguo Gao, Danel Wang, Arianna Bonilla, Mohanraj Dhanabal, Mahasweta Girgenrath, Natarajan Sethuraman

Entrada Therapeutics, Boston, MA

To overcome current limitations of oligonucleotide therapeutic delivery, we have designed a family of proprietary cyclic CPPs that form the core of our Endosomal Escape Vehicle (EEV™) technology covalently conjugated to oligonucleotides. Through screening a library of EEVs, we identified EEVs for functional delivery to target cell and tissue types. We employed our EEV-PMO (phosphorodiamidate morpholino oligomer) technology in Duchenne muscular dystrophy (DMD) preclinical models and evaluated the ability of our EEV-PMO conjugates to upregulate specific gene expression via exon skipping. In DMD, mutations result in a reading frame shift causing a lack of functional dystrophin. In mice harboring a *DMD* exon 23 nonsense mutation, we showed that monthly doses of an exon 23-skipping EEV-PMO resulted in restoration of dystrophin protein in skeletal and cardiac muscle. Next, we applied our EEV-PMO approach to down-regulate interferon regulatory factor 5 (IRF5) gene expression. Overexpression of IRF5 is associated with inflammatory and autoimmune diseases. To knockdown IRF5, we identified steric blocking oligonucleotides that modulate splicing, promote out-of-frame shift, and knockdown *IRF5* mRNA level. Treatment with an IRF5-targeting EEV-PMO resulted in potent and dose-dependent knockdown of IRF5 *in vitro* and *in vivo*, indicating the applicability of our EEV-PMO approach in modulating gene expression in immune cells. These results demonstrate the ability of our EEV platform to efficiently deliver oligonucleotides to specific target cell and tissue types. In addition, our approach has broad applicability to up- or down-regulate target gene expression through distinct mechanisms of action.

1634 Optimization of a Suicide Gene Vector for the GEN2 Cancer Immunotherapy Clinical Trial

Cecilia Roh, Joseph McNulty, Jacqueline Fischer-Lougheed, Makoto Sato, Robert G. Johnson

GenVivo, Inc., San Marino, CA

The optimization of a suicide gene which serves to unmask neoantigens within tumor cells and generate immune activation was undertaken using a series of criteria focused on more effective distribution of the suicide gene within the tumor cells and better selectivity for the prodrug, ganciclovir (GCV). GEN2 is a highly engineered non-replicating Moloney Murine Leukemia Viral (MoMLV) vector encoding for a modified Herpes Simplex Virus Thymidine Kinase (HSV-TK) suicide gene. HSV-TK is an enzyme that locally converts an orally administered prodrug activator (valganciclovir) into a toxic cellular metabolite that ultimately induces cell death in transduced and nearby cancer cells, release of neoantigens into the tumor microenvironment and activation of local and system immune responses. These responses include increased uptake of tumor cell antigens by dendritic cells, maturation of various other antigen presenting cells for enhanced antigen capture, more cross-priming of T cells, and increased tumor infiltration by, and activation of, cytotoxic T cells. In order to enhance the cell killing activity of HSV-TK, three strategies were used. 1. The distribution of HSV-TK was enhanced in the cytosol of the targeted cancer cells by: a. modification of nuclear localization signal (NLS) which results in uniform distribution of HSV-TK in the nucleus and cytosol; b. insertion of a nuclear export signal (NES) at the 5' terminus of the HSV-TK sequence to relocate HSV-TK into the cytoplasm. Distribution of the HSV-TK enzyme to the cytosol enhances the cellular efficiency of conversion of the GCV to its active toxic metabolite and also the availability of this metabolite to affect surrounding cancer cells through bystander effect. 2. Increasing selectivity of HSV-TK for GCV over thymidine was achieved through the mutation of the substrate binding domain. 3. The optimization of the coding sequence for the HSV-TK was achieved through: a. codon optimization to remove rare and low use codons to improve HSV-TK protein expression; b. lowered GC content within the newly codon optimized gene to avoid gene synthesis and other gene expression problems; c. removal of known splice acceptor and splice donor sequences within the optimized gene along removal of polypyrimidine tracts that may be involved in splicing; d. to further optimize expression of HSV-TK protein, a strong Kozak translation initiation sequence was introduced in front of the start codon while removing possible Kozak sequences within HSV-TK open reading frame. Overall, the combination of all modifications renders GEN2 more potent in cancer cell killing compared to all other vectors tested. GEN2 (HSV-TK-GMCSF) is currently being evaluated in a Phase I clinical trial.

1635 TROCEPT-01: A Tumor Targeted Oncolytic Adenovirus Vector for Delivery of Immunotherapeutic Payloads by Intravenous Administration

Alexander T. Baker[1], Rahul C. Khanolkar[1], James A. Davies[1], Thomas A. Webb[1], Lucy M. Williams[1], Samantha L. Moore[1], Johanne M. Pentier[1], Bent K. Jakobsen[2], Alan L. Parker[3], David K. Cole[1], Andrew B. Gerry[4]

[1]R&D/Pre-Clinical, Accession Therapeutics, Oxford, United Kingdom,[2]Accession Therapeutics, Oxford, United Kingdom,[3]Cardiff University, Cardiff, United Kingdom,[4]Pre-Clinical, Accession Therapeutics, Abingdon, United Kingdom

Background Immune checkpoint inhibitors (ICIs) have revolutionized immunotherapy, but efficacy and response rates are limited, dependent on the ability of patient T cells to recognize and activate against tumor antigens. Additionally, systemic delivery can lead to dose limiting toxicity. These, and other treatment modalities, would benefit from efficient localized tumor delivery to minimize off-target toxicity and maximize efficacy at the point of need. TROCEPT is a novel tumor-selective delivery technology, based on adenovirus, engineered to

prevent sequestration in normal tissues. Removal of normal tissue tropisms addresses the main limitation of other viral therapies: hepatic sequestration. TROCEPT is further engineered to specifically bind to a tumor marker, αvβ6 integrin, expressed on most carcinomas, and carry transgenes encoding immune checkpoint inhibitors for in-tumor delivery. Once delivered, this results in a function ICI being concentrated at the point of need. Thus, TROCEPT-01 enables tumor-localized generation of ICI payloads. In this study we demonstrate that TROCEPT-01 overcomes these limitations,to deliver ICI's specifically to tumors, by I.V. administration, without off target sequestration, at high titers. **Methods** TROCEPT-01 was rationally engineered using recombineering. αvβ6 integrin-dependent cell entry of TROCEPT-01, production of ICIs in multiple tumor cell lines, and functionality of *in-tumor* generated ICI was confirmed *in vitro*. Finally, a murine model engrafted with a human αvβ6 integrin-positive tumor, was used to assess biodistribution of TROCEPT-01, after intravenous delivery, using a bioluminescence *in vivo* imaging system and qPCR. **Results** *In vitro* testing confirms TROCEPT-01's exquisite selectivity for tumor cells expressing αvβ6 and ablation of native viral tropisms. We show high titer expression of functional ICI's in cancer cell lines. *In vivo* experiments demonstrate TROCEPT-01 is well tolerated and it's biodistribution is tumor-localized, with high concentrations of ICI in the tumor and low concentrations of ICI detected in peripheral blood. **Conclusions** TROCEPT displays an improved biodistribution profile compared to other I.V. oncolytic viral vectors. It's tumor selective transgene delivery and production of ICIs enables high titer local dosing of the tumor, addressing systemic toxicity and potentially increasing efficacy. Delivery of ICI's via TROCEPT has the potential for synergistic cancer cell killing by expressing viral associated antigens and cell lysis, driving immune cell infiltration, while breaking tumor immune tolerance. Reduced off target infection enables a greater proportion of the therapy to reach the tumor than other oncolytic virus approaches which rely on non-specific cell entry. Therefore, TROCEPT represents an exciting next-generation viral vectored immunotherapy for αvβ6 positive cancers.

1636 VE-Cadherin Gene Editing Shows a Kaiso-Dependent Loss of Vasculogenic Mimicry in Uveal Melanoma Cells

Daniel Delgado-Bellido[1], Ana Belen Herrera-Campos[1], F. Javier Oliver[1], Angel Garcia-Diaz[2]

[1]Instituto de Parasitología y Biomedicina López-Neyra., CSIC, Armilla. Granada, Spain,[2]Instituto de Parasitología y Biomedicina López-Neyra, CSIC, Armilla. Granada, Spain

Solid tumors require blood vessels for growth, and access to oxygen and nutrients, and anti-angiogenic therapies are designed to target vascular endothelial cells (ECs) to form tumor blood vessels. Although numerous preclinical models have recognized the efficient use of angiogenesis inhibitors to limit tumor growth, collectively only a growth delay has been achieved in the clinic. In 1999, Maniotis et al. presented a new interpretation of previous findings describing cancer cells covering non-endothelial vascular channels that contained red blood cells. This initial report defined tumor cell Vasculogenic Mimicry (VM) as the de novo formation of perfused, matrix-rich, vasculogenic-like network in a three-dimensional (3D) matrix in vitro, which resembled the matrix-rich network observed in aggressive tumors in patients. The presence of VM is associated with a high tumor grade, short survival, invasion, and metastasis. ECs express various members of the cadherin superfamily, in particular vascular endothelial (VE-) cadherin (VEC), which is the main adhesion receptor of endothelial adherent junctions. Aberrant extra-vascular expression of VEC has been observed in certain cancer types associated with VM. VEC is a trans-membrane protein commonly expressed in the endothelium, where it is responsible for cell-cell adhesion. Although VEC used to be considered specific for ECs, its expression has been strongly associated with aggressiveness and VM in melanoma. In the current study, we have elucidated the mechanistic link leading from elevated accumulation of phosphorylated VEC (pVEC) to induction of VM in metastatic uveal melanoma (UM). Focal adhesion kinase (FAK) is a cytoplasmic tyrosine kinase co-activated by integrin and VEGFR-2 receptors in the control of vascular permeability. Recent studies have shown that the VECY658 residue prevents targets FAK in tumour-associated ECs, and endothelial FAK activity inhibits tumor metastasis by enhancing barrier function. Using a co-immunoprecipitation approach, we show that VEC forms a complex with p120 and the transcriptional repressor kaiso into the nucleus. Abrogation of VEC phosphorylation, through FAK inhibition (PF-271), diminished complex formation and its nuclear import. Interestingly, the pVEC (Y658) depletion forced the accumulation of VEC and p120 in the cytoplasmic fraction. In addition, aberrant extravascular expression of VE-cadherin has been observed in certain MV-associated cancers. Gene-edited MUM2B uveal melanoma cells, deficient in VE-cadherin by CRISPR/Cas9 technology, show loss of the ability to develop VM. Moreover, rescue of wild-type VE-cadherin reversed the ability to form MV; conversely, expression of VE-cadherin Y658F blunted MV in vitro. On the other hand, Kaiso is a member of the BTB/POZ subfamily of zinc finger proteins (POZ-ZF); which recognizes and binds a specific DNA consensus sequence (kaiso binding sites KBS, TCCTGCnA, as a transcriptional repressor). Previous studies have shown that kaiso forms a complex with p120, which prevents kaiso binding to its target genes promoters such as CCDN1, and WNT 11or MMP-7 among others. Chromatin Immunoprecipitation Assays (ChIP) reveal that both FAK and VEC silencing robustly increased kaiso binding to the WNT11 and CCND1 promoters and then negatively regulated kaiso-repressor activity, which resulted in abrogation of VM in vitro. These results establish a molecular paradigm associating pVEC with VM transformation of uveal melanoma cells owing to its ability to modulate p120 nuclear localization and kaiso-dependent gene expression.

1637 A S-HUDEP2 Reporter Cell Model to Monitor HBG Regulation for Treating Sickle Cell Disease

ByoungYong Yoo, So Hyun Park, Gang Bao

Rice University, Houston, TX

Sickle cell disease (SCD) is an inherited hemoglobinopathy caused by a single point mutation in the β-globin gene (*HBB*), which leads to sickle hemoglobin (HbS) instead of adult hemoglobin (HbA) and causes severe pain, end organ damage and early mortality. CRISPR/Cas9 based gene-editing for treating SCD has been developed to induce fetal hemoglobin (HbF) which is a major hemoglobin in the

fetus. Although HbF is suppressed after birth, inducing an elevated HbF level by gene editing has shown promise to reduce morbidity and mortality among SCD patients. However, studies on HbF induction are limited by a conventional method to measure HbF level by intracellular staining followed by flow cytometry. The intracellular staining includes fixation of live cells, laborious sample preparation, and significant cell loss. These procedures damage DNA and hinder long range PCR, which is necessary to thoroughly investigate genetic modifications or large deletions that may contribute reactivation of HbF. We identified HbF induction by *HBB* cutting, but investigation on the mechanism behind it has been limited.Here, we established a fluorescent reporter cell model that enables monitoring HbF expression in living cells to overcome limitations from conventional intracellular staining. In Sickle-Human Umbilical cord Derived Erythroid Progenitor 2 (S-HUDEP2), which is an immortalized $CD34^+$ hematopoietic stem and progenitor cell line with a sickle mutation in the *HBB*, we integrated mTagBFP2 gene at the C-terminus of *HBG1/2* by delivering HiFi *Sp*Cas9/gRNA targeting the *HBG* stop codon and a double-stranded DNA donor encoding P2A-mTagBFP2-polyA. We established single cell clones and identified one clone, H6, that clearly shows changes in BFP expression according to changes in HbF expression. In H6, 13% of cells expressed BFP^+ and 7% of cells expressed $HbF(FITC)^+$ in expansion and it was increased to 45% BFP^+ and 49% $HbF(FITC)^+$ after erythroid differentiation. We used H6 to perform gene-editing by HiFi *Sp*Cas9/sgRNA targeting *BCL11A* erythroid enhancer and erythroid differentiated for 8 days to induce HbF. After editing and erythroid differentiation, % BFP^+ cells was increased to 66% and % $HbF(FITC)^+$ cells was increased to 75%. We performed additional gene-editing by HiFi *Sp*Cas9/sgRNA targeting sickle mutation in *HBB* and erythroid differentiated for 8 days to see if % BFP^+ cells can represent % HbF^+ cells with a high correlation. We found that 72% of cells expressed BFP^+ and 90% of cells expressed $HbF(FITC)^+$ after editing *HBB* and erythroid differentiation. We drew a correlation between % HbF^+ cells and % BFP^+ cells induced by erythroid differentiation, gene-editing in *BCL11A* erythroid enhancer and *HBB*, and confirmed a high correlation with R^2 of 0.95. This high correlation indicated H6 can precisely represent % HbF^+ induced cells by % BFP^+ cells. Next, we sorted BFP^{high} and BFP^- from *HBB* edited H6 and performed long-range PCR followed by fragmentation and barcoding for Illumina MiSeq next generation sequencing (NGS) to identify allele profiles of cells expressing high HbF. More large deletions (27.6%) were found in BFP^{high} than in BFP^- (18.5%) and bulk *HBB* edited H6 (19.9%). The high frequency of large deletions in BFP^{high} indicates that large deletions generated by *HBB* cutting may contribute to HbF induction.In this study, we were able to establish single cell clones for the HBG-BFP reporter cell model and showed that H6 can precisely represent % HbF^+ by % BFP^+. We further used the clones to investigate HbF induction by *HBB* cutting and showed a relation between large deletions in *HBB* and HbF induction.In conclusion, the S-HUDEP2 HBG-BFP cell model can easily monitor HbF expression by BFP, and it can be utilized in other studies such as mechanism studies or gene-editing screening for HbF induction.

1638 AAV9.BVES Delivery Improves Muscular Dystrophy and Arrhythmia in a Mouse Model of LGMDR25

Haiwen Li, Renzhi Han

Pediatrics, Indiana University School of Medicine, Indianapolis, IN

Limb-girdle muscular dystrophy type R25 (LGMDR25) is caused by recessive mutations in BVES (blood vessel epicardial substance), characterized by progressive muscular dystrophy with muscle weakness and defective cardiac rhythm conduction in patients. Currently, there is no cure for LGMDR25 patients. Here we report the efficacy and safety of recombinant adeno-associated virus 9 (AAV9)-mediated delivery of human BVES driven by a muscle-specific promoter MHCK7 (AAV9.BVES) in a newly established BVES-knockout (BVES-KO) mouse model. First, intramuscular injection of AAV9.BVES efficiently transduced and significantly improved skeletal muscle histopathology and function of BVES-KO mice. Next, systemic delivery of AAV9. BVES following intraperitoneal injection into neonatal BVES-KO mice resulted in body-wide transduction of skeletal and cardiac muscles, with dramatic improvement in body weight gain, muscle mass, muscle strength, and exercise performance regardless of gender. AAV9.BVES also significantly mitigated the histopathological features of muscular dystrophy. Moreover, the heart rate reduction was normalized in BVES-KO mice under exercise-induced stress following systemic AAV9. BVES delivery. Finally, intravenous AAV9.BVES administration into adult BVES-KO mice after the disease onset also resulted in substantial improvement in body weight, muscle mass, muscle contractility, and stress-induced heart rhythm abnormality. No obvious adverse effects were detected. Taken together, our results provide the proof-of-principle evidence to support the AAV9.BVES gene therapy for LGMDR25.

1639 Re-Development of Glybera: A Novel Adeno-Associated Virus Gene Therapy for the Treatment of Lipoprotein Lipase Deficiency

Neel Mehta[1], Renald Gilbert[2], Parminder S. Chahal[3], Maria J. Moreno[4], Nasha Nassoury[3], Nathalie Coulombe[3], Viktoria Lytvyn[3], Mario Mercier[4], Dorothy Fatehi[4], Wendy Lin[1], Emily M. Harvey[1], Lin-Hua Zhang[5], Nazila Nazemi-Moghaddam[3], Seyyed Mehdy Elahi[3], Colin J. D. Ross[6], Danica B. Stanimirovic[4], Michael R. Hayden[1]

[1]Dept of Medical Genetics, Centre for Molecular Medicine and Therapeutics, BC Children's Hospital Research Institute, University of British Columbia, Vancouver, BC, Canada,[2]Dept of Production Platforms & Analytics, Dept of Bioengineering, Human Health Therapeutics Research Centre, National Research Council Canada, McGill University, Montreal, QC, Canada,[3]Dept of Production Platforms & Analytics, Human Health Therapeutics Research Centre, National Research Council Canada, Montreal, QC, Canada,[4]Dept of Translational Biosciences, Human Health Therapeutics Research Centre, National Research Council Canada, Ottawa, ON, Canada,[5]Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada,[6]Dept of Medical Genetics, Faculty of Pharmaceutical Sciences, Centre for Molecular Medicine and Therapeutics, BC Children's Hospital Research Institute, University of British Columbia, Vancouver, BC, Canada

Lipoprotein lipase deficiency (LPLD) is a monogenetic recessive disease caused by mutations within the lipoprotein lipase (LPL) gene, resulting in the production of a catalytically inactive protein. LPLD causes accumulation of chylomicrons within the blood that leads to severe hypertriglyceridemia and occurrence of life-threatening complications such as pancreatitis. We previously developed Alipogene Tiparvovec (Glybera), the first adeno-associated virus (AAV) gene replacement therapy product to receive regulatory approval in the western world for the treatment of LPLD. However, Glybera is no longer marketed due to economical considerations. The aim of this study was to develop a more efficacious and cost-effective AAV-based gene therapy formulation for the treatment of LPLD. Briefly, all novel AAV formulations, including Glybera, encoded either a luciferase transgene or a gain-of-function human LPL^{S447X} transgene. The transgene was driven by several ubiquitous and tissue specific promoters and packaged in several AAV serotypes. All AAV formulations were delivered intramuscularly (quadriceps) in adult mice with LPLD at either 1.0E+11 gc/kg (low dose) or 1.0E+12 gc/kg (high dose). Mice were followed for up to 80 days post-AAV treatment. Plasma lipemia, triglycerides and transgene expression were assessed throughout the study to determine therapeutic efficacy. Plasma biochemistry (liver enzymes), immune markers (cytokine array), tissue pathology and biodistrubtion were assessed at study endpoint. Our studies revealed a novel formulation, pVR59, that resulted in complete normalization of plasma triglycerides (>98% plasma triglyceride lowering from baseline) in LPLD mice at 10-fold lower doses compared to Glybera. Our biodistribution studies revealed prominent gene transfer within the injected skeletal muscle and liver following treatment with pVR59. Furthermore, pVR59 was found to be well tolerated with no systemic or localized toxicity. Our results collectively suggest that it is feasible to develop a superior AAV-based gene therapy product for the treatment of LPLD. The identification of a novel AAV formulation that is superior to Glybera at lower doses, when paired with recent advances in AAV manufacturing processes and scale-up, will translate to deliver a potent drug with increased safety and efficacy, at a lower manufacturing cost.

1640 Nanotein's NanoSpark Expands Stemlike T Cells

Zachary Imam, Curtis Hodge

Nanotein Technologies, Berkeley, CA

Cellular therapies are the cancer treatment of the future. These therapeutics work by efficiently seeking cancer cells for targeted destruction, while leaving healthy cells intact. CAR-T cells are the most clinically and commercially advanced of anti-cancer cell therapies. While incredibly effective, they have faced multiple challenges including manufacturing failures, long manufacturing times, and short-lived or poor treatment outcomes. Nanotein's novel platform technology, NanoSpark, can help overcome these challenges by accelerating the speed of CAR-T expansions, enhancing expansion to grow more cells per treatment, and shifting the growth profile of CAR-T cultures to favor the most long-lived and clinically effective CAR-T cell sub-populations, the stem-like central memory T cells (T_{scm}). Here we show that Nanotein's NanoSpark STEM-T formulation achieves enhanced expansion of total live T cells, total live $CD8^+$ cells, and $CD8^+$ T_{scm} cells during 10-day expansions of donor peripheral blood T cells. Taken together, these results demonstrate that Nanotein's NanoSpark technology can quickly expand T cells to high numbers while maintaining the therapeutically desirable, less differentiated T_{scm} subpopulation in $CD8^+$ T cells.

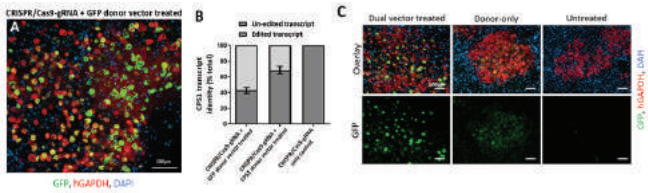
1641 Correcting CPS1 Deficiency in Primary Human Hepatocytes *In Vivo* Using AAV Delivered Cell-Cycle Independent Genome Editing

Sharntie Christina[1,2], Cindy Zhu[1], Samantha L. Ginn[1,2], Ian E. Alexander[1,2,3]

[1]Gene Therapy Research Unit, Children's Medical Research Institute, Westmead, Australia,[2]Faculty of Medicine and Health, The University of Sydney, Westmead, Australia,[3]Sydney Children's Hospitals Network, Westmead, Australia

Background: Carbamoyl phosphate synthetase I (CPS1) deficiency is a rare genetic metabolic disorder that prevents or impairs the metabolism of blood ammonia. Loss of function of the CPS1 enzyme can cause neonatal death, or intellectual disability in surviving patients. The only treatment option for severe CPS1 deficiency is liver transplantation, however the disease is an ideal candidate for gene therapy. An effective and durable gene therapy for CPS1 deficiency must create permanent changes to the genome of hepatocytes such that therapeutic effects are maintained during paediatric liver growth. Additionally, repair must overcome a high threshold for therapeutic benefit that directly correlates to hepatic cell mass corrected. We aimed to develop a cell-cycle independent targeted genome editing approach to treat CPS1 deficiency in patient-derived primary human hepatocytes *in vivo*.
Methods: The $Fah^{-/-}$ $Rag2^{-/-}$ $Il2rg^{-/-}$ (FRG) mouse model is immunodeficient and Fah negative, allowing for the engraftment and selective expansion of primary human hepatocytes. A dual

recombinant adeno-associated virus (rAAV) based approach was designed to deliver CRISPR/SaCas9 guided editing machinery and a promoter-less *GFP* or *CPS1* cDNA donor cassette for homology-independent genome insertion at the *CPS1* locus, under the native promoter. Both vectors were packaged in NP59 AAV capsid which is highly human hepatotropic. Wild-type (WT) human hepatocytes were engrafted into the FRG mouse and treated with vector ~11 weeks post engraftment at a dose within $1x10^{11}$vg/mouse to $5x10^{11}$vg/mouse. Vector treated mice were analyzed 6 weeks post injection. **Results:** A cohort of FRG mice engrafted with WT human hepatocytes (n=9) treated with $1x10^{11}$vg/mouse, $2.5x10^{11}$vg/mouse, or $5x10^{11}$vg/mouse of rAAV-NP95 CRISPR/SaCas9+gRNA vector only were analyzed for insertion/deletion (InDel) events at the Cas9 cut site. A dose of ≥800 vector genome copies per human diploid cell (via ddPCR), which correlated to $5x10^{11}$vg/mouse, was found to produce the maximum InDel events at the target loci. WT engrafted FRG mice treated with dual rAAV-CRISPR/SaCas9+gRNA vector and rAAV-*GFP* or -*CPS1* cDNA donor vectors, $5x10^{11}$vg/mouse of each vector, were analyzed for expression and genomic integration (n=4 per donor vector). Dual treated mice that received GFP donor vector showed GFP expression in up to 80% of human hepatocytes *in vivo* via immunofluorescence (Fig A). Successful integration of *GFP* or *CPS1* donor cDNA at the *CPS1* locus was observed in all dual-treated mice, as well as high levels of edited *CPS1* transcript compared to native transcript (Fig B). Thorough safety investigation of unwanted off-target events is currently under investigation. Mice treated with rAAV-*GFP* donor vector only at $5x10^{11}$vg/mouse show lowed levels of GFP expression compared to dual-treated mice, likely from off-target insertion (Fig C). **Conclusion:** These results validate our approach as a highly efficient gene integration system, able to target and edit a significant proportion of human hepatocytes *in vivo*. Our approach will be further investigated for phenotypic correction and safety in patient-derived CPS1-deficient primary human hepatocytes *in vivo*.



1642 Development of a Multi-Functional Peptide for Enhanced Efficacy of siRNA

Jessie Boulos, Jorrian Abadeer, Tyler Willis, Kay Russi, Angela Alexander-Bryant

Clemson University, Clemson, SC

Glioblastoma Multiforme (GBM), a grade VI glioma, is an aggressive malignant tumor associated with a poor prognosis. With an incidence rate of 3.19 per 100,000, GBM has a median survival rate of 12-15 months and a five-year survival rate less than 5%. Typical treatments involve surgical removal, chemotherapy, and radiation; however, these result in low survival and harm to healthy cells. RNAi has demonstrated promise for treating many diseases through targeting specific mRNA to inhibit translation; however, significant barriers to delivery hinder the clinical translation. These barriers include non-specific delivery, insufficient cellular uptake, and lack of endosomal escape. Three classes of peptides have demonstrated the ability to overcome these specific barriers: targeting, cell-penetrating, and fusogenic peptides, respectively. Although these peptides have been studied individually, few studies have evaluated the effects of combining peptides to overcome multiple delivery barriers. Thus, this study aims to design a novel multifunctional peptide, or tandem peptide, for the delivery of siRNAs to treat GBM. Combining peptide sequences would provide synergy in their characteristics, developing more efficient nanocarriers. The tandem peptide combines a fusogenic peptide, 599, and EGFR-targeting peptide, GE11. A cationic tail creates a positive charge for electrostatic complexation with siRNA. STAT3, the target gene for RNAi, is an oncogene that plays a role in cell proliferation, differentiation, apoptosis, and angiogenesis in GBM. Therefore, it is hypothesized that the tandem peptide will enhance efficacious delivery of siRNA into glioblastoma cells, resulting in more effective STAT3 gene silencing compared to the fusogenic and targeting peptides alone. We have established the tandem peptide electrostatically complexes and protects free siRNA from degradation in mimicked physiological conditions, indicating stable complexes for clinical translatability. Characterization analysis of the peptide/siRNA complexes revealed formation of uniform, monodisperse, and positively charged nanoparticles (Figure 1a). These complex characteristics are favorable for delivery to cancer cells and interactions with the cellular membrane. Western Blots confirmed basal expression of the target receptor, EGFR, and the target oncogene, STAT3, in an array of GBM cell lines. A viability assay showed no difference in viability between cells treated with the peptide compared to untreated cells, indicating minimal toxicity. Fluorescent uptake imaging and flow cytometry showed the tandem peptide increased internalization of siRNA in GBM cells. To determine gene silencing capability, the tandem peptide was complexed with STAT3 siRNA and transfected into GBM cells. qPCR analysis shows the tandem peptide's ability to reduce the STAT3 mRNA, especially at a 60:1 ratio (Figure 1b). Future *in vitro* work will include confirming gene silencing through western blots and evaluating the downstream effect of STAT3 silencing through migration and invasion assays. Assays will be completed with the individual peptides as a comparison to evaluate the tandem peptide for improved delivery of bioactive siRNA. Future work will also focus on *in vivo* therapeutic potential of delivering tandem/siSTAT3 complexes for GBM.

1643 Oncolytic Adenovirus Armed with Interferon Alpha Elicits Systemic Antitumor Immunity in Syrian Hamster Pancreatic Cancer Models

Kazuho Inoko[1], Margarita Romanenko[1], Sacha Robert[1], Shuhei Shinoda[1], Mizuho Sato-Dahlman[1], Kari Jacobsen[1], Takuro Noguchi[2], Masato Yamamoto[1], Julia Davydova[1]

[1]Department of Surgery, University of Minnesota, Minneapolis, MN,[2]Department of Medical Oncology, Hokkaido University, Sapporo, Japan

Background: Pancreatic ductal adenocarcinoma (PDAC) remains a highly fatal disease due to an immunosuppressive tumor microenvironment. Our strategy focuses on the use of oncolytic adenoviruses (OAds) as cancer therapeutics. OAds are designed to selectively replicate and spread within a tumor, resulting in immunogenic cell death (ICD), which releases damage-associated molecular patterns, evoking strong antitumor immune responses. OAds are also capable of highly efficient delivery of immune-stimulating genes to cancer cells, achieving high concentrations of the gene products within the tumor. Here, we employed a replication competent OAd expressing syngeneic IFN-α (OAd-IFN), one of the most promising cytokines for combination strategies in cancer immunotherapy, and assessed its potential for therapeutic application in PDAC. **Methods and Results:** For this study, we developed novel immunological tools to assess the immunomodulatory role of OAd-IFN in immunocompetent Syrian hamsters. Unlike commonly used mouse models, Syrian hamsters are permissive to OAd replication, providing an advantage in predicting OAds behavior in humans. To identify the role of type I IFN in antitumor activity, we employed the identical luciferase-expressing control virus (OAd-Luc). We first evaluated the cytotoxicity of OAd-IFN and its gene production in hamster PDAC cell lines. OAd-IFN showed significantly higher cytotoxicity compared to OAd-Luc. OAd-IFN infected PDAC cells secreted IFN-α in a dose and time dependent manner, indicating efficient gene expression. Next, we examined inflammatory responses by quantitative RT-PCR, and found that a variety of proinflammatory chemokine genes, including CXCR3 ligands, and MHC I were upregulated in OAd-IFN infected cells compared to OAd-Luc infected or uninfected cells. The level of extracellular ATP measured by bioluminescent assay was also significantly increased in OAd-IFN infected cells, suggesting the potential of OAd-IFN to induce ICD. We then evaluated *in vivo* therapeutic and immunomodulatory activities of OAd-IFN. Syrian hamsters bearing HP-1 PDAC tumors in both flanks were treated intratumorally with OAd-IFN or OAd-Luc ($2.5x10^9$ pfu/injection), or PBS unilaterally every three days for a total of four injections. To evaluate the systemic efficacy ("abscopal effect") of OAd-IFN, the right flank tumor was left untreated. Compared to PBS and OAd-Luc treated groups, OAd-IFN showed significant tumor growth inhibition not only in the injected tumors, but also in the non-injected distant sites. Median survival was significantly improved in the OAd-IFN group (PBS: 27 days, OAd-Luc: 36 days, IFN-OAd: 40.5 days) without any adverse events. Importantly, we confirmed that, in this model, infectious viral particles (as quantified by $TCID_{50}$ assay) were restricted to only the injected sites, and were not responsible for the abscopal effect. These data suggest potential for OAd-IFN to induce direct oncolysis and systemic antitumor immunity *in vivo*. The underlying mechanisms of this phenomenon are currently being investigated using newly developed immunological assays for Syrian hamster models, including spatial transcriptome analysis. **Conclusion/Future directions:** This study demonstrated the potential of OAd-IFN to induce systemic antitumor immunity in immunocompetent OAd-permissive models, and will provide crucial knowledge for clinical translation of OAd-IFN-based therapies for PDAC.

1644 Developing Novel AAV Capsids for Ophthalmic Gene Therapy

Cenfeng Chu[1], Huifang Zhang[1], Guodong Jia[2], Guisheng Zhong[3]

[1]Shanghai EmayGene Biotech Co. Ltd., Shanghai, China,[2]OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China,[3]ShanghaiTech University, Shanghai, China

Gene delivery tools are the key for gene therapy for different diseases, including vision diseases. AAVs are often used to deliver genes to many different organs in basic and translational research. However, there are no effective AAVs to transduce the retina cells in an efficient and specific manner. Here, we modified the AAV capsids to create AAV libraries, and then we identified the potential AAVs with an in vivo animal screening strategy. In this study, we discovered a novel AAV variant, named as AAV-WM01, which can infect retinal pigment epithelium (RPE) cells efficiently in mouse retina by intravitreal injection. Further experiments indicated that AAV-WM01 specifically transduce RPE cells with high efficiency and specificity. Importantly, AAV-WM01 can deliver the gene for anti-VEGF to substantially alleviate the wAMD symdromes in the non-human primate animal model. Based on these exciting pre-clinical results, we are carrying out clinical studies to treat wAMD with AAV-WM01, and the clinical results are expected to release this year. Furthermore, we have found a couple of AAV variants can transduce other layer cells in the retina with high efficiency by intravitreal injection, which may hold the potential to treat other types of vision diseases.

1646 Intravenous Administration of AAV-GLA Corrects Substrate Level in the Mouse Model of Fabry Disease

Shaoyong Li[1], Pengfei Yu[1], Zhongwan Li[1], Xiaodong Pang[1], Lijun Wang[1], Jianhua Mao[2], Zhihong Lu[2], Zhenhua Wu[1], Guo-jie Ye[1]

[1]Exegenesis Bio Inc., Lower Gwynedd, PA,[2]Department of Nephrology, The Children's Hospital, Zhejiang University School of Medicine, Hangzhou, China

Fabry disease (FD) is a rare X-linked metabolic disorder caused by deficiency of lysosomal enzyme α-galactosidase A (α-Gal A) due to pathogenic mutations in the GLA gene.The progressive accumulation of substrates within lysosomes results in cellular dysfunction and multiple organ damage. The current enzyme replacement therapy is an effective treatment for FD, however, bi-weekly lifelong infusions are significant burdens for patients. To provide a single administration with long-lasting effects, we aim to develop a recombinant adeno-associated virus (rAAV) vector-based gene therapy for FD. The codon-optimized human GLA (hGLA) cDNA with minimal CpG was generated with two

algorithms. A series of synthetic hepatotropic promoters were evaluated *in vitro*. An optimized transgene expression cassette was then selected and packaged into AAV9 (scAAV9-hGLA). A single intravenous injection of scAAV9-hGLA to 10-week-old α-Gal A KO male mice resulted in dose-dependent α-Gal A activity in the serum, liver, heart and kidney. Stable expression of α-Gal A in serum sustained until the end of 8-week mouse study. Compared to wild type mice treated with vehicle control (buffer), the GLA-KO mice received the lowest dose (2×10^{11} vg/kg) showed 178-fold (×), 58×, 3×, 0.8× of α-Gal A activity in serum, liver, heart and kidney, respectively. The GLA-KO mice treated with 2×10^{12} vg/kg of scAAV9-hGLA showed 2360×, 1378×, 119×, 10× of α-Gal A activity. The highest dose (2×10^{13} vg/kg) resulted in up to 18,485× of α-Gal A activity in the serum. As lyso-Gb3 is a biomarker for FD, we used liquid chromatography-tandem mass spectrometry (LC-MS/MS) to quantify the substrate level. Compared to GLA-KO mice treated with vehicle control, all the AAV-treated GLA-KO mice showed significantly reduced lyso-Gb3 level in the serum. The 2×10^{11} vg/kg of scAAV9-hGLA treatment reduced the lyso-Gb3 to 2.5% of that of GLA-KO control mice. Three higher doses (2×10^{12}, 6×10^{12} and 2×10^{13} vg/kg) of treatment completely normalized the lyso-Gb3 level in the serum, liver, heart and kidneys. The codon-optimized hGLA transgene mRNA level correlated with AAV vector genome copies in the liver and showed a dose-dependent effect. Liver-derived robust human α-Gal A protein expression and proper glycosylation was demonstrated by western-blot. The immunostaining confirmed the presence of α-Gal A in the liver, heart and kidney. Histopathologic examination showed no observed toxicity with all the doses. Finally, we demonstrated that the effective dose can be further minimized by using an in-house developed novel liver-muscle tropic capsid AVT908 and promoter. Our data support development of low-dose AAV-GLA gene therapy for Fabry disease.

1647 IKC151V is a Bi-Cistronic Vector to Treat Retinal Conditions Associated with Significant Vascular Remodelling for the Treatment of Wet-AMD and Diabetic Retinopathy

Katie M. Binley, Emily F. Warner, Laura Vaux, Kara Boyd, Andrew Osborne, Peter Widdowson

Ikarovec Limited, Norwich, United Kingdom

Purpose: Wet-form age-related macular degeneration (wAMD) and diabetic retinopathy (DR) are two of the most prevalent and debilitating retinal conditions and are associated with significant vascular remodelling, characterised by new blood vessel growth, vascular leakage, fibrosis, and degrees of inflammation. Frequently administered anti-VEGF therapeutics are the mainstay for the management of these conditions. Connective tissue growth factor (CTGF) is involved in vascular remodelling in both conditions and has been hypothesised to play a key role in the development of subretinal scars and capillary basal lamina thickening in wAMD and DR, respectively. We have designed a bi-cistronic AAV vector (IKC151V) that expresses a novel anti-VEGF component (VEGF-Capture2/VC2), with a modified Fc domain which reduces immune complex formation and transport into the systemic circulation, combined with a CTGF-attenuating component which is predicted to display greater efficacy in both eye diseases than anti-VEGF agents alone. **Methods:** The Fc-binding affinity of the recombinant novel VC2 protein was compared to aflibercept using ELISA-based assays. Null control vector (IKC166V), a vector expressing aflibercept alone (IKC163V) and IKC151V were administered bilaterally via the intravitreal route of delivery in the murine laser-induced CNV model. CNV leakage and lesion volume, were evaluated by fluorescence angiography (FA) and optical coherence tomography (OCT), whilst lesion area and transgene expression were evaluated via choroidal flatmounts and ELISA. In the *Vldlr-/-* knockout mouse model of CNV and subretinal fibrosis, IKC151V and IKC163V were administered intravitreally and neovascular leakage was assessed by FA. **Results:** The VC2 component in IKC151V displays reduced affinity for both human FcRn (IC_{50}: aflibercept= 34 nM, VC2= 24 microM) and Fc gamma-RI (IC_{50}: aflibercept= 20 pM, VC2= 63 microM). Using laser-induced CNV, IKC151V significantly reduced the lesion severity scores and lesion volume versus Null control vector at day 7, and performed better than the mono-cistronic aflibercept (IKC163V) 14 days after laser treatment (lesion volume (10^7 microns^3): Null= 1.66 ± 0.33, IKC163V= 0.80 ± 0.12*, IKC151V= 0.36 ± 0.08*; *p ≤0.001). The reduction in lesion size by IKC151V was greater than IKC163V despite significantly lower vitreous levels of anti-VEGF protein (IKC163V= 7.1 ± 3.2 microg/mL, IKC151V= 4.9 ± 1.7 microg/mL*; *p ≤0.01). Similarly, IKC151V treated *Vldlr-/-* mice demonstrated a reduced lesion severity score compared to IKC163V treated eyes (IKC163V= 0.79 ± 0.86, IKC151V= 0.35 ± 0.42) and a reduced total number of lesions (IKC163V= 0.39 ± 0.62, IKC151V= 0.0 ± 0.0). **Conclusion:** In IKC151V, the reduced affinity of VC2 for both FcRn and Fc gamma-RI receptors gives a greater safety potential over aflibercept. In two models of vascular remodelling, IKC151V was able to attenuate developing and existing neovascularisation to a greater extent than IKC163V expressing aflibercept alone, thus demonstrating an important role for CTGF in this pathology. These data support the therapeutic potential of IKC151V for the treatment of retinal conditions associated with significant vascular remodelling such as wAMD and DR.

1649 Characterization of Genomic Instability in Hematopoietic Stem Cells of *Blm*$^{tm3Brd/tm3Brd}$ Mice for Pre-Clinical Trial of Lentiviral Gene Transfer to Prevent Bloom Syndrome Related Hematological Malignancy

Kazuhiro Noguchi, Yasuhiro Ikawa, Mika Takenaka, Yuta Sakai, Toshihiro Fujiki, Rie Kuroda, Taizo Wada

Pediatrics, Kanazawa University Hospital, Kanazawa, Japan

Introduction: Bloom syndrome is a monogenic disease caused by the *BLM* gene mutation that leads to genomic instability and a predisposition to cancer. Some of the main characteristics of this genetic disorder are elevated sister chromatid exchange (SCE) and hypersensitivity to inter-strand cross-linking agents, such as mitomycin C (MMC), leading to the development of hematological malignancies. As patients do not have tolerance for cytotoxic chemotherapy or radiotherapy, hematological malignancies often result in a refractory clinical course and a poor prognosis. To address these issues, we plan to establish a preclinical trial of lentiviral gene transfer to hematopoietic stem cells (HSCs) to prevent the development of hematological malignancies in patients with Bloom syndrome. Although various mouse models with *Blm*-mutant alleles do not survive to term, *Blm*$^{tm3Brd/tm3Brd}$ (*Blm*$^{m3/m3}$) mice have been reported as a viable and fertile mouse

model for Bloom syndrome. Moreover, *Blm*$^{m3/m3}$ mice have been reported to have predispositions to cancer, such as leukemia and lymphoma. Therefore, *Blm*$^{m3/m3}$ mice might be an ideal mouse model for preclinical trials. However, the characteristics of HSCs in terms of genomic instability, such as SCE elevation and MMC hypersensitivity, remain unclear. In this study, we analyzed the frequency of SCE and sensitivity to MMC in HSCs from *Blm*$^{m3/m3}$ mice to identify markers that can potentially measure gene therapy effects. Methods: 1. MMC sensitivity assay: Lentiviral vectors (LV) encoding the *BLM* gene with green fluorescent protein (GFP) were pseudotyped using the vesicular stomatitis virus (VSV-G) envelope (VSV-G-BLM-GFP-LV). Harvested HSCs from *Blm*$^{m3/m3}$ mice and wild-type (WT) C57BL/6 mice were pre-stimulated in stem cell growth media, supplemented with murine cytokine thrombopoietin (100 ng/mL), Flt3L (100 ng/mL), and stem cell factor (100 ng/mL) for 5 h at 100,000 cells/mL. Pre-stimulated HSCs were cultured for 48 h in medium containing only hexadimethrine bromide at a final concentration of 4 μg/mL and in medium containing hexadimethrine bromide along with VSV-G-BLM-GFP-LVs (MOI: 50) at 100,000 cells/mL. For methylcellulose colony-forming unit assays, 500 cells of transduced HSCs were plated into MethoCult M3534 medium. To elucidate the sensitivity of HSCs to MMC, they were cultured in MethoCult medium containing increasing concentrations of MMC (0-0.5 nM MMC). After 14 days of culturing, the number of colonies was counted. 2. SCE analysis: HSCs collected from *Blm*$^{m3/m3}$ and WT mice were incubated with bromodeoxyuridine (BrdU). The number of SCEs in metaphase chromosome spreads was then counted in 20 HSCs from each of the *Blm*$^{m3/m3}$ and WT mice. Results: 1. MMC sensitivity assay: *Blm*$^{m3/m3}$ HSCs did not show higher sensitivity to MMC than WT HSCs. VSV-G-BLM-GFP-LV transduction did not improve the sensitivity of MMC in *Blm*$^{m3/m3}$ HSCs. 2. SCE analysis: The number of SCEs in *Blm*$^{m3/m3}$ HSCs was approximately two-fold higher than that in WT HSCs. Discussion: According to our experiments, *Blm*$^{m3/m3}$ HSCs did not show high sensitivity to MMC. One of the reasons might be that the Blm mutant protein in *Blm*$^{m3/m3}$ mice has been reported to retain 25% WT activity. Therefore, this retention of WT activity of the Blm mutant protein may result in a lack of high sensitivity to MMC. However, *Blm*$^{m3/m3}$ HSCs showed a two-fold increase in the number of SCEs compared with WT HSCs. In conclusion, to advance pre-clinical trials, the evaluation of SCEs can be used as a valid marker to measure the functional effect of gene transfer in HSCs of *Blm*$^{m3/m3}$ mice.

1650 Transient Immune-Modulation Can Reduce the Immune Response Induced After Systemic *In Vivo* Administration of INS-101 Lentiviral Gene Therapy

Carolina Caserta, Pauline Gillino, Cassandre Tavernier, Thierry Alvarez, Baptiste Simone, Lionel Simoes Da Silva, Stephanie Sarrazy-Garcia, Elvire Gouze, Alain Martelli, Guillaume Kulakowski

Innoskel, Biot, France

Innoskel is developing a lentiviral-based gene therapy approach to treat individuals with Spondyloepiphyseal Dysplasia congenita (SEDc). SEDc is a rare genetic bone disorder caused by mutations in the *COL2A1* gene and is associated with progressive skeletal deformities that are life-threatening and require repeated surgical procedures. Our gene therapy product INS-101 is a lentivirus (LV) that delivers a wild-type *COL2A1* transgene to cartilage growth plates to correct the molecular cause of the disease. Preclinical evaluation of INS-101 has demonstrated efficacy in a SEDc mouse model. INS-101 systemic injection *in vivo* is associated with an immune response to the LV. This response might decrease therapeutic efficacy, lead to adverse events, and prevent redosing of INS-101 in patients. We characterized the LV-induced immune response in mice, primates or minipigs and evaluated the ability of immune-modulatory drugs to reduce or prevent it. IgG and IgM responses directed to the LV, as well as neutralizing antibodies were detected in the serum of LV-injected animals. The release of pro-inflammatory cytokines was also observed shortly after injection, and a specific LV-directed cellular response was seen by ELISpot using isolated splenocytes. We tested several immunosuppressive drugs via repeated injections around the time of the LV administration in mice: effects of Anti-CD20, Anti-BAFF, Methotrexate (MTX), Mycophenolate Mofetil (MMF), Tacrolimus, Prednisolone and Rapamycin were monitored alone or in combination. LV-specific IgG and IgM levels, as well as neutralizing antibody titers, were significantly reduced by some individual or combination treatments. The ability of a regimen including Prednisolone, Tacrolimus and MMF in reducing the LV-induced humoral immune response was also demonstrated in minipigs. Together, our results indicate that a transient immune-modulatory treatment can effectively and durably impair the LV-induced immune response.

1651 Immunosafety of AAV Gene Therapy Vectors: Induction of Cytokine Release and Complement Activation

Rebecca Xicluna[1], Emily Seeger[1], Julian Freen-van Heeren[2], Annelies Turksma[2], Rianne Opstelten[2], Timo Schwandt[3], Petra Schwalie[4], Desiree Von Tell[5], Emma Bell[5], Hélène Haegel[1]

[1]I2S, Roche pRED Pharmaceutical Sciences, Basel, Switzerland,[2]Immunomonitoring Services, Sanquin Health Solutions, Amsterdam, Netherlands,[3]Translational Safety Assessment, Roche pRED Pharmaceutical Sciences, Basel, Switzerland,[4]Predictive Modelling & Data Analytics, Roche pRED Pharmaceutical Sciences, Basel, Switzerland,[5]Genetics & Genomics, Roche pRED Pharmaceutical Sciences, Basel, Switzerland

Gene therapy mediated by recombinant adeno-associated virus (rAAV) is one of the most promising approaches for the treatment of a variety of inherited and acquired diseases. Multiple variants of AAV vectors have established themselves as powerful tools for *in vivo* gene transfer, allowing long lasting and safe transgene expression in a variety of clinical trials. Nevertheless, the immune response against these vectors, and particularly its capsid, remains a major limitation for gene transfer. Upon administration, rAAV vectors stimulate both innate and adaptive immune responses. The innate response stimulates adaptive immunity, leading to the formation of anti-AAV capsid antibodies, which prevent the transduction of target cells and preclude successful vector re-administration. Moreover, the innate immune response can contribute to toxicities. Adverse events in several systemic gene therapy clinical trials have been linked to complement activation, leading to decreases in platelets and red blood cells, and to acute kidney injury. We assessed

the effects of AAV2 and AAV8 vectors on the production of a large panel of cytokines and chemokines in whole blood from healthy human donors (n=18). In order to investigate the role of pre-existing anti-AAV antibodies on cytokine release and complement activation, these experiments were conducted in whole blood from both seropositive and seronegative donors. The results showed that AAV vectors could trigger low but detectable levels of cytokines and chemokines (IFN-α, IFN-β, IFN-γ, IL-1b, IL-2, IL-6, IL-8, IL-10, IP-10, MCP-1, MIP-1α, MIP-1β and TNF-α) in whole blood from a proportion of the AAV-seropositive donors tested, but not in all of them. Notably, the IFN-α release was almost undetectable with empty AAV capsids, supporting the hypothesis that IFN-α release is triggered by the genome through TLR9 activation. We used single-cell RNA sequencing to characterize the cytokine-producing cells in whole blood at different time points. The results showed that the production of cytokines was mainly driven by monocytes, NK cells and T cells. Interestingly, increases in several of these cytokines and chemokines were observed in the serum of mice after injection of a high AAV8 dose. We also investigated the mechanism of complement activation by AAV capsids by measuring increases in C3a and C5a in whole blood from a large cohort of donors (n=20). Complement activation occurred in an AAV dose-dependent manner and mainly in the presence of anti-AAV antibodies. No difference was observed in complement activation whether empty or full AAV capsids were used for whole blood treatment. Our results show that complement activation by AAV is antibody-dependent and mediated through the classical pathway. Our work also highlights the interest of monitoring cytokine release in clinical trials to better understand its impact on the adaptive immune response and the clinical outcome. Lastly, investigating the effects of AAV vectors on cytokine release in whole blood may allow identifying less inflammatory and safer AAV vectors.

1652 A Recombinant Adenovirus Vector Containing the *synNotch Receptor* Gene Inhibits Tumor Growth of Triple-Negative Breast Cancer in a Mouse Xenograft Model

A. Ruhan[1], Koichi Kitagawa[1], Naoto Kunimura[1], Masato Fujisawa[2], Toshiro Shirakawa[3]

[1]Kobe University Graduate School of Science, Technology and Innovation, Kobe, Japan,[2]Kobe University Graduate School of Medicine, Kobe, Japan,[3]Kobe University, Kobe, Japan

Introduction: Triple-negative breast cancer (TNBC) is one of the most difficult molecular subtypes of breast cancer to treat. We developed a recombinant replication-deficient adenoviral vector (Ad-CD44-N-HIF-3α4) containing a gene encoding a synthetic Notch (synNotch) receptor composed of the extracellular domain of CD44 (CD44-ECD) and the hypoxia-inducible factor (HIF)-3α4 connected by the Notch core regulatory region. CD44 is a cell surface adhesion receptor and a known cancer stem cell marker in breast cancer and other malignancies. HIF-3α4 is a dominant-negative regulator of HIF-1α in TNBC cells. The CD44-ECD in the synNotch receptor acts as a CD44 decoy receptor, and after a ligand binds to the CD44-ECD, HIF-3α4 is released, resulting in the inhibition of both CD44 and HIF-1α signaling pathway in cancer cells by transduction of *CD44-Notch-HIF-3α4* fusion gene into TNBC cells. **Methods:** In this study, we employed a human TNBC cell line, MDA-MB-231. Gene transduction with recombinant adenoviral vector containing a fusion gene *CD44-Notch-HIF-3α4* (Ad-CD44-N-HIF-3α4) and the gene expressions were determined. MDA-MB-231 cells were cultured under conditions of hypoxia (≤2% O_2). Ad-CD44-N-HIF-3α4 and a control Ad-LacZ were infected into cells at 50 multiplicities of infection (MOIs), respectively. To determine the cell proliferation, 2,000 cells/well MDA-MB-231 cells were treated with 50 MOI of Ad-CD44-N-HIF-3α4 or Ad-LacZ and incubated at 37°C for 5 days at hypoxic or normoxic condition *in vitro*. *In vivo* study, MDA-MB-231 cells were subcutaneously inoculated into mice. Intratumoral injections were performed with 1×10^9 PFU of adenoviral vectors Ad-CD44-N-HIF-3α4, Ad-LacZ, and PBS control. **Results:** Besides the endogenous CD44 protein, we confirmed the transductions of decoy CD44-ECD proteins in MDA-MB-231 cells in dose dependent manners. The mRNA expression of *HAS2* in MDA-MB-231 cells was significantly increased compared to SV-HUC-1 cells, while the mRNA expression of *HAS1* and *HAS3* were not changed ($p<0.01$). In addition, the relative gene expressions of *survivin* and *CCL2*, downstream genes of CD44, in the cells infected with Ad-CD44-N-HIF-3α4 were significantly lower than in cells infected with Ad-LacZ and control cells under culture conditions of hypoxia ($p<0.01$). The relative gene expression of *vascular endothelial growth factor* (*VEGF*), a hypoxia target gene, was significantly decreased in the cells infected with Ad-CD44-N-HIF-3α4 than that in control cells under culture conditions of hypoxia ($p<0.01$). In the cell proliferation analysis, Ad-CD44-N-HIF-3α4 significantly inhibited the cell growth of MDA-MB-231 cells in normoxia and hypoxia conditions compared to cell only (no treatment) group ($p<0.01$). Transwell invasion assay, Ad-CD44-N-HIF-3α4 significantly inhibited the cell migration of MDA-MB-231 cells in hypoxia condition but not in normoxia condition ($p<0.05$). Furthermore, Ad-CD44-N-HIF-3α4 significantly suppressed tumor growth compared to Ad-LacZ or PBS control in mice ($p<0.01$). The expression of CD44 was remarkably increased in mice tumors with the treatment of Ad-CD44-N-HIF-3α4. **Conclusion:** Ad-CD44-N-HIF-3α4 inhibited the both signaling pathways of CD44 and HIF-1α in MDA-MB-231 cells under conditions of hypoxia *in vitro*, and significantly suppressed tumor growth both *in vitro* and *in vivo*. These findings indicated that Ad-CD44-N-HIF-3α4 has a high clinical applicability for invasive types of TNBC.

1653 Transcriptomic Profiling of the Mouse Hippocampus After Intracerebral Injection of Cas9 Nanocapsule Genome Editors

Kirstan Gimse[1], Yuyuan Wang[1], Jesi Felton[2], Jeanette Metzger[2], Marina Emborg[2], Jon Levine[2], Shaoqin Sarah Gong[1], Krishanu Saha[1]

[1]Wisconsin Institute for Discovery, University of Wisconsin- Madison, Madison, WI,[2]Wisconsin National Primate Research Center, University of Wisconsin- Madison, Madison, WI

Evaluating the editing efficiency and cell-type specificity of genome editors is a critical task for developing somatic cell genome editing strategies, especially for those that target the brain. Standard methods rely on deep sequencing at the on-target site combined with immunohistochemistry within treated animal model systems to enumerate the types of edited cells in select tissues after administering genome editors. Animal reporter systems that express fluorescent

proteins after successful on-target genomic editing provide robust platforms to evaluate the number of edited cells but typically incorporate limited opportunities to co-register cell-type markers with the reporter protein. Thus, molecular characterization of an edited cell typically is limited to 2-4 cell-type markers that can be imaged simultaneously with the fluorescent reporter. Here, we report on a new approach to deeply characterize the transcriptome of edited cells within the brain of Ai14-tdTomato reporter mice. We performed single nucleus RNA sequencing (snRNA-seq) on nuclei isolated from hippocampi after intracranial injection of nanoparticle genome editors into the dorsal hippocampus. We utilized a previously developed biodegradable nanocage (NC) capable of delivering a preassembled SpyCas9 protein-gRNA ribonucleoprotein complex (RNP). RNPs targeting the Ai14 loxP-STOP cassette were encapsulated into these NCs and delivered into the dorsal hippocampus via intracranial injection. After performing snRNA-seq, we observe the capture of ~500-15000 unique transcripts per nuclei and robust Ai14-tdTomato reporter expression in nuclei from neuronal, glial, and oligodendrocytic cells. Additionally, differential cell-type specific transcriptomic shifts were identified primarily in immune and cell signaling pathways between treatment with recombinant adeno-associated viral vectors (rAAV) or NC. Overall, transcriptional profiling provides a high-resolution and complementary method to examine the cellular outcomes from genome editing within animal reporter systems, which has high potential to inform the clinical development of genome editing therapeutics.

1654 Bioprinted Liver Tissues as a Cell Therapy for Phenylketonuria

Zainab Bazzi, Farin V. Livary, Stephanie Campbell, Haley Tong, Simon Beyer, Tamer Mohamed, Sam Wadsworth, Spiro Getsios, Rafal P. Witek, Christopher TD Dickman

Aspect Biosystems, Vancouver, BC, Canada

Background: Phenylketonuria (PKU) is an autosomal recessive disorder, affecting approximately 1:10,000 newborns worldwide. PKU is caused by mutations to the *PAH* gene, resulting in aberrations in the phenylalanine hydroxylase (PAH) enzyme. Given that PAH converts phenylalanine to tyrosine, individuals with PKU have elevated plasma phenylalanine concentrations, resulting in profound intellectual disability if left untreated. Current treatment for PKU involves controlling plasma phenylalanine levels via a phenylalanine-restrictive diet. Adherence to this diet is problematic, with compliance decreasing in adolescence and adulthood. While efficacious, liver transplantation is not a viable treatment for PKU due to its invasiveness, long-term immune suppression, and limited supply of donor organs. Herein, we use a unique microfluidic 3D bioprinting technology to demonstrate the ability of a bioprinted hepatocyte-containing tissue to metabolize phenylalanine to treat PKU. **Methods:** Primary human hepatocytes (PHHs) were aggregated into spheroids with and without mesenchymal stromal cells (MSCs). Spheroids were then 3D bioprinted in an alginate-based tissue using Aspect Biosystems' microfluidic 3D bioprinting technology. To assess phenylalanine metabolism *in vitro*, bioprinted liver tissues were challenged with media containing 2 mM phenylalanine. Conditioned media was collected over 7 days and phenylalanine was quantified using a fluorogenic assay. Additionally, bioprinted liver tissues were assessed for viability, albumin secretion, gene expression, and Cyp3A4 activity. **Results:** Bioprinted tissues containing PHHs and PHHs/MSCs were able to metabolize >500 nmol of phenylalanine/million PHHs/day, when challenged with PKU-relevant concentrations of phenylalanine *in vitro*. Gene expression analysis indicates bioprinted tissues express PAH, suggesting their ability to restore PAH activity. Furthermore, these bioprinted tissues demonstrate additional liver specific function, such as albumin secretion (>10 μg/million PHHs/day) and cytochrome P450 activity over a period of 7 days. **Conclusions:** Bioprinted hepatocyte-containing tissues are capable of metabolizing physiologically relevant levels of phenylalanine and maintaining function *in vitro* in the long term. This demonstrates that bioprinted tissues containing PHHs represents a viable therapeutic strategy for the treatment of PKU. Further studies are warranted to assess the efficacy of bioprinted hepatocyte-containing tissues on phenylalanine metabolism in a small animal model of PKU.

1655 Thermosensitive Hydrogel-Based Spatiotemporally Controlled Gene Therapy

Yesol Kim, Kang Juwon, Juyeong Mun, Kye Il Joo

Division of Chemical Engineering and Materials Science, Ewha Womans University, Seoul, Korea, Republic of

Biomaterials such as hydrogel, microneedle and nanofiber are widely used in drug and gene delivery. Especially, hydrogels are unique biomaterials that have demonstrated tremendous potential in localized drug delivery with high drug-loading ability, great biocompatibility, and sustained & controlled drug release. In this study, we aimed to develop a dual delivery system of thermosensitive hydrogel incorporating DNA-complexes with various functional polymers and cell penetrating peptides for spatiotemporally controlled gene therapy. This approach involves developing thermosensitive mPEG-PLGA hydrogel possessing sol-gel transition property in the response to temperature change and facilitating the encapsulation and sustained release of therapeutic genes. For an enhanced gene delivery to target cells, we formulated a DNA-complex with various polymers and cell penetrating peptides, which could enhance cell uptake, endosomal escape, and transfection efficiency. Indeed, DNA complexed with RALA peptide showed great gene delivery efficiency with lower cytotoxicity compared with commonly used transfection agents. Overall, this dual delivery system demonstrates excellent capability for spatiotemporally controlled gene therapy, thereby exhibiting great potential for use as a gene therapeutic platform for many diseases.

1656 Safety of Ascending Doses of AAVrh.10hFXN to Treat the Cardiac Manifestations of Friedreich's Ataxia

Jonathan B. Rosenberg[1], Alessandria Greco[1], Carlos Munoz Zuluaga[1], Monica La Russa Gertz[1], Melissa Yost-Bido[1], Nicholas C. Gorman[1], Alvin Chen[1], Vikrum Kooner[1], Bishnu P. De[1], Stephen M. Kaminsky[1], Rodolfo J. Ricart Arbona[2,3], Heather R. Martin[2,3], Sebastien Monette[2,3], Richie Khanna[4], Ronald G. Crystal[1], Dolan Sondhi[1]

[1]Department of Genetic Medicine, Weill Cornell Medicine, New York, NY,[2]Center for Comparative Medicine and Pathology, Memorial Sloan Kettering Cancer Center, New York, NY,[3]Weill Cornell Medicine, New York, NY,[4]LEXEO Therapeutics, Inc., New York, NY

Friedreich's ataxia (FA) is caused by a GAA trinucleotide expansion in the first intron of the frataxin gene (FXN), resulting in a reduction in frataxin mRNA and protein levels. Following development of neurologic disease, individuals homozygous for FA develop cardiac dysfunction at age 20 to 25 and cardiac disease is the leading cause of death at an average age of 37.5 yr. Previous studies in murine models the cardiac manifestations of FA established that adeno-associated virus (AAV) serotype rh.10 expressing human frataxin (AAVrh.10hFXN) at an intravenous dose of $1.8x10^{12}$ gc/kg mediated cardiac frataxin levels in the range of asymptomatic heterozygous carriers, resulting in improvement in the cardiac manifestations of FA (Munoz Zuluaga C, et al, Mol Ther 2022; 30 4S1:444). This study sought to establish the safety of this dose in mice and nonhuman primates for potential use in a human clinical trial. AAVrh.10hFXN was administered intravenously (IV) to wildtype C57Bl/6N mice (n=24F/24M per dose cohort) at 3 increasing half-log doses of $1.8x10^{12}$ ("low"), $5.7x10^{12}$ ("mid"), and $1.8x10^{13}$ gc/kg ("high"), with a control group administered PBS. Mice were weighed and evaluated for health and behavioral assessments weekly. Mice were evaluated at 1, 3 and 10 months for toxicity, FXN levels in liver and heart, troponin levels, total antibody and neutralizing antibody titers, biodistribution of the AAV genome and organ histopathology. At the low dose of $1.8x10^{12}$ gc/kg there were no adverse treatment-related findings except 1 male mouse in the 10-month necropsy group had hepatocellular carcinoma. The mid-dose cohort showed mild to moderate hepatic toxicity evident in clinical chemistry and in histopathology at 3 months, and 3 of 12 male mice had hepatocarcinoma at 10 months. High dose mice expressed greatly elevated frataxin levels in liver, had decreased body weight and severe hepatic toxicity. In the context that hepatocarcinoma is a sporadic observation in inbred mice treated with AAVs but has not been observed in nonhuman primates or humans, to provide additional confidence in the safety profile of AAVrh.10hFXN, we evaluated the safety of AAVrh.10hFXN administered IV in African Green nonhuman primates (NHP; n=10), at $5.7x10^{11}$ or $1.8x10^{12}$ gc/kg doses (n=2/sex/dose), plus PBS controls (1/sex). All NHPs were administered prednisolone immunosuppression pre-dose and continuing throughout the study. All animals survived to the scheduled euthanasia, 3 months post-dose. No abnormal clinical signs were observed and there were no vector-related effects on body weight, organ weight, macroscopic differences or blood parameters. There were no microscopic findings of hepatocarcinoma or hepatotoxicity. Echocardiograms 3-months post-vector administration were normal. On average, the increase in cardiac FXN expression after AAVrh.10hFXN administration with $5.7x10^{11}$ and $1.8x10^{12}$ gc/kg doses was 6.5 and 37%, respectively, over the PBS-treated controls. Together, these data identify the safe doses of AAVrh.10hFXN relevant for the treatment of the cardiac manifestations of FA.

1657 Full-Length rAAV Sequencing for Mixture Population Characterization Using Highly Accurate Long Reads

Elizabeth Tseng, Harsharan Dhillon, Roger Volden

Pacific Biosciences, Menlo Park, CA

Recombinant Adeno-associated virus (rAAV) is one of the most actively investigated gene therapy vehicles. Understanding the quality of rAAV vectors by assessing the presence of cellular impurities such as truncations, chimeras, and host genome integrations are all essential for ensuring the purity and safety of the vector. While next-generation sequencing has been applied for assessing the quality of rAAV vectors, short read length technologies cannot sequence the full-length AAV molecules, which are necessary for identifying these impurities. Furthermore, short read sequencing cannot accurately distinguish or quantify mixed populations that might contain both scAAV and ssAAV. We demonstrate that using highly accurate long reads (HiFi reads) from PacBio, we can accurately characterize rAAV mixtures. PacBio SMRT sequencing is a long-read sequencing technology that can produce reads of >Q20 (>99%) for insert sizes of 10 kb - 20 kb and longer, which easily cover the entirety of typical rAAV constructs. To demonstrate the PacBio long read sequencing can accurately characterize AAV constructs, we purchased scAAV and ssAAV constructs from commercial vendors. We created sequencing libraries from both supposedly pure (scAAV or ssAAV-only) vectors and also an artificially mixed (scAAV with ssAAV) population. The long read data was able to characterize the proportion of vector genomes for truncation (full-length or partial), purity, structure (self-complementary or single-strand). To summarize, we show that the long read sequencing has the ability to accurately and comprehensively assess the safety, potency, and purity of rAAV vectors, making it a valuable tool for the quality assessment of rAAV genome populations.

1658 An Illustrative Example from the PaVe-GT Program for Navigating FDA Orphan Drug and Rare Pediatric Disease Designation Applications

Richa Madan Lomash[1], Oleg Shchelochkov[2], Randy J. Chandler[2], London Toney[1], Deanna Portero[3], Charles P. Venditti[2], Anne Pariser[3], Elizabeth Ottinger[1]

[1]Therapeutic Development Branch, NCATS, Rockville, MD,[2]National Institutes of Health, Bethesda, MD,[3]National Center for Advancing Translational Sciences (NCATS), Bethesda, MD

There are over 10,000 known rare diseases and more than 90% have no cure or treatment. Many of these diseases occur in very small patient populations, leading to a lack of commercial interest in developing new treatments for such orphan indications. Platform Gene Vector Therapy (PaVe-GT) is developing gene therapies for four disorders with very low prevalence. Along the process of PaVe-GT

implementation, we plan to publicly share our regulatory and scientific experience from different stages utilizing illustrative examples. The first gene therapy candidate of PaVe-GT, adeno-associated virus, AAV9-hPCCA to treat PA has been granted Orphan Drug Designation (ODD) and Rare Pediatric Disease Designation (RPDD) from the FDA. ODD and RPDD are FDA programs to facilitate the development of orphan drugs in the US by providing financial incentives for sponsors. Our application process is outlined in accordance with FDA requirements. Described in detail are: a) Prerequisites for an ODD and RPDD application and a checklist of the requirements, as defined by the FDA; b) Approaches to providing proof of direct benefit to trial participants and potential therapeutic effectiveness in the rare disease; c) Steps and approaches to accurately estimate patient population size in the US, required to establish the orphan status of the disease or condition; d) Resources for preparing a successful ODD/ RPDD application; e) Templates and AAV9-hPCCA redacted applications. Both these programs for orphan drugs have been shown to have a positive correlation with innovation, investor valuation and investments in rare disease research and development. The resources and process presented to prepare an ODD application can benefit parties with limited experience and understanding of the regulatory requirements and serve as a guide in the preparation of a similar application for their orphan product.

1659 Moving Past the BBB - Screening for the Most Functional CNS-Tropic AAV

Jessica Merjane[1], Heledd Brown-Wright[2], Luan Luu[3], Roger Chung[3], Adam Walker[2], Leszek Lisowski[1]

[1]Children's Medical Research Institute, Sydney, Australia,[2]The University of Queensland, Sydney, Australia,[3]Centre for Motor Neuron Disease Research, Sydney, Australia

The use of recombinant adeno-associated viral vectors (rAAV) as a gene delivery tool has demonstrated great potential for both therapeutic gene therapy and scientific research. One of the key benefits of rAAV is the ability to alter the tropism and transduction efficiency of different serotypes and variants by engineering the viral capsid. Recent advances in vector bioengineering technologies have improved our understanding of vector interactions with target cells, allowing researchers to rapidly evolve novel AAV variants and introduce targeted changes within existing rAAV capsids. These changes aim to improve overall vector properties, such as tropism, production capacity, stability, and immunogenicity. Due to the increasing maturity of this technology, there are now hundreds of academic and commercial teams working in a wide array of preclinical models to engineer AAVs for a range of organs and cell types. However, this decentralised approach to vector bioengineering leads to a lack of studies that directly compare vectors developed by individual groups. Vectors developed for specific targets are also not evaluated for their potential superior properties in other applications. Given the vast number of engineered rAAVs now available, it is worth considering whether efficient vectors can be repurposed for targeting other organs of interest, such as the central nervous system (CNS). Despite the progress in rAAV targeting, the CNS remains a challenging target due to the limited ability of AAV serotypes to efficiently cross the blood-brain-barrier (BBB) and transduce the CNS when injected intravenously (IV). Intravenous injections can be disadvantageous for targeting the CNS as they require vectors to be capable of crossing the highly selective BBB, whilst they also increase the risk of off-targeting peripheral organs, such as the liver. Additionally, there is a lack of rAAVs that can target specific regions/cell types in the CNS. We have developed an AAV screening tool to assess the ability of known and characterised AAV variants to transduce the CNS of mice when injected passed the BBB via intrathecal (IT) or intracerebroventricular (ICV) injection. Fifty-seven (n=57) AAV variants were screened head-to-head to identify top-performing candidates at the RNA level within specific brain regions, including cerebellum, hippocampus, cortex, and spinal cord of both adult and P0 mice. Interestingly, top-performing vectors were similar in both injection methods, however, results demonstrate unique vector tropisms for specific regions and cell types in the CNS. Following the screening process, top AAV variants were assessed individually to evaluate and compare transduction efficiency and tropism. Following this exciting proof-of-concept study, we currently seek to expand into more clinically relevant models, such as non-human primates (NHP).

1660 GMP Production of a Cas9 3xNLS Protein for the Treatment of Sickle Cell Disease

Alicia D. Powers[1], Jason Hatfield[1], Aixia Ren[1], Timothy Lockey[1], Michael M. Meagher[1], Aaron Shafer[1], Jonathan Yen[2], Rachel Levine[2], Erin Dempsey[2], Nikitha Nimmagadda[2]

[1]Therapeutics Production and Quality, St. Jude Children's Research Hospital, Memphis, TN,[2]Hematology, St. Jude Children's Research Hospital, Memphis, TN

Sickle cell disease is a genetic red blood cell disorder that causes hemolysis, anemia, vaso-occlusion, organ damage, and pain in millions of individuals across the world. Gene editing using a modified Cas9 protein and guide RNA to reactivate fetal hemoglobin offers a potentially curative therapy for this disease. In this work, we describe the growth and purification of a tag-less modified Cas9 3xNLS protein from *E. Coli* in a GMP suitable process for use in St. Jude's gene editing program to treat sickle cell disease, termed St. Jude Autologous Genome Edited Stem cells (SAGES-1). SAGES-1 is an autologous gene editing strategy to target the -113 site of the γ-globin promoter to induce HbF. While affinity tag purification of recombinant proteins is suitable for research purposes, this approach is not preferred in Good Manufacturing Practice (GMP) applications due to the need to remove and test for contaminating affinity labels in the final product. A bioreactor (5L) is inoculated from an overnight shake flask culture of a producer cell line. Cells grow overnight in the bioreactor at 30°C with an exponential feed until they reach an OD_{600} of 60-80, after which the temperature is decreased to 20°C and the culture is induced with IPTG. Culture is harvested 21-23 hours after induction. Harvested culture is homogenized and filtered before purification over a Sepharose SP column, incubation with allantoin, and further purification over a Ceramic Hydroxyapatite Type 1 column. The purified Cas9 protein is diafiltrated and concentrated to 12 mg/mL by tangential flow filtration before vialing. *E. Coli* produces endotoxin, which can stimulate an immune response of fever and inflammation. Our initial purification process left with a high level of endotoxin in the final product. Addition of 100 mg/mL allantoin, a small crystalline powder, and the use of a Ceramic Hydroxyapatite Type 1 column reduced this level to acceptable levels. The average yield of the process over three runs was

1.2 mg protein per g of wet pellet weight and the purity was greater than 95% as measured by reverse phase UPLC, SDS-CGE, and Size Exclusion Chromatography. Furthermore, we have compared Cas9 3xNLS protein made with this method over several batches and shown the batches to be consistently highly active in both *in-vitro* cleavage assays and in CD34+ hematopoietic stem cells. These batches of GMP-like Cas9 are going into our IND-enabling *in vivo* pharmacology and toxicology studies.

1662 Microfluidic Production of Nanogels as Alternative Triple Transfection Reagents for the Manufacture of AAVs

Zoe Whiteley, Giulia Massaro, Georgios Gkogkos, Asterios Gavriilidis, Simon N. Waddington, Ahad A. Rahim, Duncan Q. M. Craig

University College London, London, United Kingdom

Introduction- AAVs represent one of the most widely studied gene delivery systems. Their production, however, remains challenging in terms of yield, cost-effectiveness and large-scale manufacture. In this work, we present an alternative triple transfection method for AAV9 production, using nanogels produced by microfluidics, compared to polyethyleneimine-MAX (PEI-MAX) polyplexes. We anticipate that this will facilitate AAV manufacturing in becoming a continuous process with high yields, rapid production and reduced costs. **Materials and Methods - Nanogel production by microfluidics** -The microfluidic coaxial flow reactor (CFR) is adapted from Whiteley *et al1*. Nanogels contained pDNA at weight ratios of 1:1:2 (pAAv: pDG9: pHGTI) at nitrogen: phosphate (NP) ratios of 1 to 20. **Small and large-scale AAV production** - PEI-MAX (2mg/mL) was added to pDNA (1:1:2 weight ratio). HEK293T cells were plated in 6-well plates and nanogels and PEI-MAX was added at 2.5µg pDNA/well. The AAV in the supernatant was measured after 72h. For large-scale production, a total pDNA quantity of 52.5µg/dish of PEI-MAX and nanogel formulations was added to 150cm^2 dishes. After 72 hours, the cells and supernatant were collected, concentrated and purified. **Results and Discussion - Particle characterization**- The aim was to produce nanogels below 200 nm and PDI below 0.3. The nanogels ranged from 116.3 nm ± 10.8 at NP10 to 187.0 nm ± 4.7 at NP5, with NP10 and 20 demonstrating significantly smaller sizes than the PEI-MAX. PDI values below 0.3 indicate a high degree of monodispersity[2]. PEI-MAX demonstrated a PDI of 0.321 ± 0.005, significantly larger than NP5 at 0.199 ± 0.013 and NP20 at 0.154 ± 0.018. TEM images of PEI-MAX polyplexes, NP10 and NP20 nanogels (Figure 1 (a-c) respectively) show the PEI-MAX polyplexes formed aggregates revealing instability.**AAV production** - The nanogels were transfected in HEK293T cells in 6-well plates. The nanogels producing the highest AAV titre were selected for large-scale manufacturing. Figure 2a shows that NP5 and NP10 nanogels produce AAV at 8.83x10^8 vg/mL ± 9.71x10^7 and 8.13x10^8 vg/mL ± 4.97x10^8, statistically equivalent to PEI-MAX at 1.09x10^9 vg/mL ± 5.44x10^8. Decreases in NP ratio to 1, resulted in a significant reduction to 4.10x10^7 vg/mL ± 1.05x10^7. The production of AAV from NP5 nanogels (7.41x10^{11} vg/mL ± 1.36x10^{11}) at large scale (Figure 2b) showed no significant difference to the titer from PEI-MAX polyplexes (1.24x10^{12} vg/mL ± 4.4x10^{11}). **Conclusions** - Microfluidic CFRs produce nanogels with viral titers equivalent to PEI-MAX. Nanogels are stable and show greater cost-effectiveness than PEI-MAX, whilst microfluidics allows for larger-scale continuous production. **References** - (1) Z. Whiteley, H. M. K. Ho, Y. X. Gan, L. 1663 Development of a Cas13-Based RNA Targeting Therapy for Neovascular Age-Related Macular Degeneration (nAMD) and Diabetic Macular Edema (DME)

Weiwei Wu[1], Jingyu Zhang[1], Qi Yang[1], Sheng He[1], Jipeng Song[1], Chenhua Yang[1], Mengke Zhu[1], Shaoran Wang[1], Xing Wang[1], Hongting Du[1], Linyu Shi[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Age-related macular degeneration (AMD) is a major cause of visual dysfunction for adults over age 50 of which the neovascular AMD (nAMD) accounted for 90% blindness in AMD. The vascular endothelial growth factor (VEGF), an angiogenic growth factor, plays a crucial role in nAMD and diabetic macular edema (DME). Although anti-VEGF agents are effective and safe in treating nAMD and DME, long-term efficacy decreases over time due to the need for repeated injections impacting patient compliance with treatment regimens, patients still may lose vision during the 7th or 8th year of the treatment. These frequent intravitreal injections can increase the risk of complications, including submacular hemorrhage, intraocular hypertension, endophthalmitis, and retinal detachment. Furthermore, many patients with nAMD do not respond well to the standard anti-VEGF therapy. **Methods**: We developed a Cas13-based RNA targeting therapy, HG202, that used a unique strategy of AAV vector combined with high-fidelity CRISPR/Cas13 RNA targeting technology to knock down the expression of VEGFA in the local retina. The choroidal neovascularization (CNV) was induced in mouse eyes

by laser photocoagulation. Fundus fluorescein angiography (FFA) and optical coherence tomography (OCT) were conducted 7 days after injury. Afterwards, choroidal flatmounts were immunostained for CNV detection. **Results**: Significant editing efficiency was observed in both *in vitro* and *in vivo*. More than 40% *Vegfa* mRNA expression was suppressed by subretinal delivery of HG202 at the optimal dose in retina (n=8) of mice. The area of laser-induced CNV was markedly reduced in mice eyes treated with HG202 at the optimal dose (87% reduction, p<0.0001, n=14). By contrast, the inhibition efficiency of AAV-anti VEGF was lower than that of HG202 (70% reduction compared to the vehicle control, p<0.01, n=14) and Aflibercept was only half as much as that of HG202 (47% reduction, p<0.01, n=18) (Figure 1). With a single injection, we achieved a therapeutic effect of at least 13 weeks in the mouse model. Additionally, HG202 was well tolerated in mice at a certain dose range. **Conclusions**: Compared with DNA editing or protein inhibitors strategies, we blocked VEGFA signaling by Cas13-mediated mRNA knockdown, enabling high efficacy, and theoretically avoiding permanently changes of DNA sequence. In summary, a single subretinal injection of HG202 enabled long-term transgene expression and RNA editing, avoiding 1- or 2-month repeated injections, and providing long-lasting therapeutic benefits for patients (with or without anti-VEGF antibody) to treat nAMD and DME. To the best of our knowledge, we are the only group using Cas13-based RNA target strategy to treat nAMD patients with or without anti-VEGF antibody.

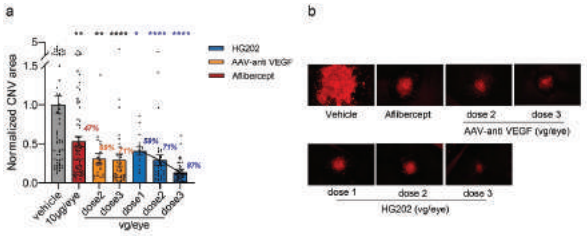

Figure 1. Inhibition of laser-induced CNV development by H202 treatment

1664 Circular RNAs Localize to Synapses in the Human Brain and Differentially Expressed in Alzheimer's Disease Implicating Critical Roles for Synaptic Function Which Could Present New Targets for Gene Therapy

Samuel N. Smukowski[1], Cassidy Danyko[2], Jenna Somberg[3], Yidian Ye[3], Eli Kaufman[3], Meredith M. Course[3], Kathryn Gudsnuk[3], Paul N. Valdmanis[3]

[1]Genome Sciences, University of Washington, Seattle, WA,[2]Molecular and Cellular Biology, University of Washington, Seattle, WA,[3]Medical Genetics, University of Washington, Seattle, WA

Circular RNAs (circRNAs) are unique transcript isoforms that may play critical regulatory roles in the human brain which could have impacts in the progression of neurodegenerative disorders such as Alzheimer's Disease (AD). CircRNAs are produced by back-splicing a later exon to a preceding exon creating a closed-loop structure. They can perform a variety of functions, in addition to being translated, including acting as microRNA "sponges" and sequestering RNA binding proteins. CircRNAs also persist in the cytoplasm due to exonuclease resistance. These multifunctional roles distinguish them as attractive targets for gene therapy. Alzheimer's Disease (AD) is the most prevalent form of dementia and is characterized by progressive accumulation of plaques consisting of amyloid beta peptide and neurofibrillary tangles of hyperphosphorylated tau protein. These molecular pathologies are followed by synaptic and neuron loss as well as cognitive impairment. Previous research demonstrated circRNAs preferentially localize to synapses and expression of many are perturbed in AD. We corroborate this evidence with the addition of novel insights using new techniques and statistical approaches, and we follow this up with determining functional roles for identified circRNAs. To discover and quantify RNA transcripts localized to the synapse in AD, we acquired more than 30 postmortem human brain samples including AD patients and controls. From homogenized brain tissue, we fractionated synaptic particles (synaptosomes) using sucrose gradient ultracentrifugation. Next, we extracted RNA from both the synaptosome fraction and homogenate, then acquired RNA sequencing data using a ribo-removal total RNA strategy which captures non-canonical isoforms. By comparing synaptosome to homogenate, we confirmed that the overwhelming majority of circRNAs are enriched in synapses. Furthermore, by comparing synaptosomes between AD and control, we discovered that there are also many circRNAs that differentially localize to synapses in AD indicating potential targets for gene therapeutic intervention in an attempt ameliorate disease. Among the most significantly differentially localized circRNAs, two isoforms of the gene *GSK3B* stood out. One isoform is a circle of exons 7, 8, and 9, and the other isoform is a circle of exons 9 and 10. Most interesting is that the former isoform is upregulated in AD with a $\log_2$ fold change of 1.5 whilst the later is downregulated in AD with a $\log_2$ fold change of -1.6. The discovery that there are two unique circular isoforms of *GSK3B* each differentially localized at synapses in AD is noteworthy since GSK3B has an established role in tau hyperphosphorylation. To investigate the impact of each of these isoforms, we transfected SH-Sy5y cells with the circ*GSK3B* exons in a plasmid containing complementary Alu elements that facilitate their circularization. We find that transfection of each of these plasmids causes contrasting protein abundance differences in the GSK3B protein as well as its phosphorylation state which could demonstrate a connection with AD molecular pathologies. We hypothesize that these circRNAs have further downstream impacts on protein expression including tau. This provides a basis for which protein expression could be modulated to treat disease by the delivery or manipulation of circRNAs which is an exciting new prospect given their multifunctional roles and stability in the cytoplasm. Here we present our work to uncover the significance of these findings which represents a novel investigation into this class of understudied molecules.

1665 PN Modification of Stereopure GalNAc-siRNAs Enhances Durability of Human *HSD17B13* Silencing in Transgenic Mouse Model

Wei Liu, Naoki Iwamoto, Subramanian Marappan, Khoa Luu, Snehlata Tripathi, Erin Purcell-Estabrook, Juili D. Shelke, Himali Shah, Anthony Lamattina, Qianli Pan, Brett Schrand, Frank Favaloro, Mugdha Bedekar, Arindom Chatterjee, Jigar Desai, Tomomi Kawamoto, Genliang Lu, Jake Metterville, Milinda Samaraweera, Priyanka S. Prakasha, Hailin Yang, Yuan Yin, Hui Yu, Paloma H. Giangrande, Michael Byrne, Pachamuthu Kandasamy, Chandra Vargeese

Wave Life Sciences, Cambridge, MA

We aimed to develop siRNAs to suppress expression of the clinically relevant liver gene *Hydroxysteroid 17-beta dehydrogenase 13* (*HSD17B13*). A loss of function genetic variant of *HSD17B13* has been associated with a reduced risk of chronic liver disease and progression from steatosis to steatohepatitis, suggesting that decreasing *HSD17B13* expression in liver could be protective against liver disease. To develop *N*-Acetylgalactosamine (GalNAc)-conjugated siRNAs targeting hepatic *HSD17B13*, we first interrogated the impact of chemical and stereochemical modifications to sense and antisense strands containing chiral phosphorothioate (PS) and phosphoryl guanidine (PN) modifications using mouse *Transthyretin* (*Ttr*) as a benchmark. We evaluated hundreds of stereopure GalNAc-siRNAs—those in which the chiral configuration (*R*p or *S*p) of chemically modified backbone linkages (PS or PN) are controlled at each position—in comparison with stereorandom GalNAc-siRNAs designed based on formats previously reported to have enhanced stability. In primary mouse hepatocytes and mouse liver, we show that a 5′-*R*p*S*p PS in the antisense strand is favored in a format with high 2′-deoxyfluoro (2′-F) content and without PN linkages. With the addition of PN linkages, the configuration of the 5′-end PS linkages becomes less important. We also show that an *S*p PS configuration on both ends of the sense strand is favored. The impact of the PN backbone on activity depends on its position in the backbone, the chirality of the linkage, and nearby 2′-ribose modifications. The potency and durability benefits observed *in vivo* with these stereopure GalNAc-siRNAs appear to be driven by improved Ago2 loading. Ultimately, we generated HSD-1930, a stereopure GalNAc-siRNA targeting human *HSD17B13* based on our learnings from optimization of GalNAc-siRNAs targeting *Ttr*. In mice that express an *HSD17B13* human transgene, a single 3 mg/kg subcutaneous dose of HSD-1930 decreased expression of *HSD17B13* mRNA in the mouse liver by ≥75% of PBS-treated controls for at least 14 weeks post-dose. By comparison, *HSD17B13* mRNA levels in the liver of mice treated with a stereorandom control were comparable to PBS-treated controls at 14 weeks. HSD-1930's silencing advantage in mice corresponded with a significant improvement in Ago2 loading. Taken together, these preclinical data provide compelling evidence that HSD-1930 is a potent and durable silencer of hepatic *HSD17B13* expression.

1666 CD33 CAR T Cells Generated by Restrained TCR Stimulation and Optimized Cytokines Manifested Potent Antileukemic Activity and Less-Differentiated Memory Phenotype

Jonas Jian Wu, Marissa M. Del Real, Jasmine Kwong, Emanuela Marcucci, Kenny Ng, Alan Macias, Tongyuan Xue, David Horne, Stephen J. Forman, Lihua E. Budde

City of Hope National Medical Center, Duarte, CA

Acute myeloid leukemia (AML) is the most common type of acute leukemia in adults with a low 5-year survival rate. Patients with unfavorable AML can't achieve long-term remission without allogeneic hematopoietic-cell-transplantation (allo-HCT), but the common subsequent relapse after allo-HCT often led to only a few months of overall survival. CD33 is a high-density antigen expressed on most AML blasts and is a safe immunotherapeutic target due to low expression on normal hematopoietic stem cells. We developed a CD33 chimeric antigen receptor (CAR) T cell product aiming to fulfill this unmet need for treating AML. Our previous clinical trial of CD123 CAR T cells was promising but identified the need for a faster CAR T cell manufacturing process. T cell proliferation and memory phenotype differentiation are heavily influenced by the strength of T cell receptor (TCR) signaling and γ-chain cytokines. We aim to shorten the manufacturing time of our CD33 CAR T cells without compromising product quantity and quality by optimizing αCD3/CD28 stimulation and cytokine combination. **Methods:** We cultured CD4+/CD8+ T cells isolated from AML patients (patient-derived; PD) or healthy donors (HD) with αCD3/CD28 Dynabeads at 1:3, 2:1, or 3:1 bead-to-cell ratio on day 0 and transduced with the lentiviral vector (huCD33scFv-CD8h-CD8tm3-41BB-Zeta(CO)-T2A-EGFRt_epHIV7) on day 1. We expanded the resulting CD33 CAR T cells in either IL2 (50U/ml) + IL15 (0.5ng/ml) or IL7 (10ng/ml) + IL15 (5ng/ml). We removed beads on either day 4 or 7 and evaluated cell expansion and immunophenotype by flow cytometry. We tested CD33 CAR T cell effort function in an AML cell model (Molm14 and KG1A) and in an AML xenograft NSG mouse model. We engrafted $1x10^6$ ffluc+Molm14 AML cells on day 0 and treated with $1x10^6$ PD CD33 CAR T cells on day 6, evaluated tumor growth via the bioluminescence imaging and monitored mouse survival. **Results:** We found that T cell expansion was higher, yielding more CD33 CAR T cells in the 4 day (4D) vs. 7 day (7D) condition. Lower bead ratio (4D/1:3-bead and 4D/2:1-bead) led to 8.6- and 11-fold more HD-derived and 2.1- and 1.4-fold more PD CAR T cells than the strongest stimulation group (7D/3:1-bead), respectively. The 4D stimulated PD CD33 CAR T cells were more effective against AML cell lines due to enhanced proliferation during tumor lysis assay: CAR T cells stimulated with 4D/1:3-bead and 4D/2:1-bead proliferated 9.0- and 3.1-fold more than the 7D/3:1-bead group, respectively. Regardless of cytokine condition, the 4D/2:1-bead condition consistently generated the most CD33 CAR T cells. PD CD33 CAR T cells showed similar expansion when cultured in either cytokine condition, while IL7/IL15 vs. IL2/IL15 led to 2.8-fold higher expansion for HD-derived CAR T cells. However, CD33 CAR T cells grown in either cytokine condition exerted comparable *in vitro* efficacy. *In vivo*, PD CAR T cells generated by 4D/2:1-bead with either cytokine condition dramatically limited tumor growth, but the condition of 4D/2:1-bead with IL2/IL15 resulted in the best survival

(100%) compared to 4D/2:1-bead with IL7/IL15 (33.3%) at day 71. Thus, we adopted the 4D/2:1-bead with IL2/IL15 for our clinical manufacturing platform. Production of CD33 CAR T cells achieved an average of 22.3- and 31-fold expansion on day 7 and 11, respectively, and manifested with a continuously increased proportion of Tn/scm (CD45RA+CD62L+) cells and decreased proportion of Tem (CD62L-) cells. **Conclusion:** Using a combination of restrained TCR stimulation (4D-2:1 bead) and IL2/IL15 cytokines, we optimized our CD33 CAR T cell production platform to yield highly proliferative CAR T cells with less-differentiated memory phenotype and potent antigen-dependent antileukemic efficacy.

1667 Development of Novel Size Exclusion Filters for Gene Therapy Applications

Amy Determan[1], Raj Rajagopal[1], Christian Krumm[2], Ki-Joo Sung[3], Jennifer Heitkamp[1], Ramona Osterloh[2]

[1]Separations and Purification Sciences Divsion, 3M, Saint Paul, MN,[2]Separations and Purification Sciences Divsion, 3M, Wuppertal, Germany,[3]Corporate Research Materials Laboratory, 3M, Saint Paul, MN

Biotherapeutics are typically produced in mammalian cell lines which carries risk of viral contamination in the final product. Nanofiltration is one of the orthogonal steps used in biotherapeutics production to remove viral contaminants. There is a need for an easy-to-use nanofiltration system to remove large viral contaminants in downstream processing of biotherapeutics prior to formulation. In this study, 3M nanofilters were tested for their ability to separate small virus particles using bacteriophages PhiX174, QBeta and PP7 (25 to 28 nm) from larger bacteriophages Phi29 (45 nm) and T7 (50 nm) representing large viral contaminants. In addition, mammalian viruses ranging in various sizes were also tested. Processing was done at either constant flow (600 LMH) or constant pressure (30 psi). 3M nanofilters showed >6 log reduction of Phi29 and T7 and no retention of the smaller viruses. Similarly, 3M nanofilters showed >4 to 7 log of mammalian viruses (>35 nm). Additionally, process interruptions had no effect on viral clearance. The phage clearance studies show the potential of using 3M nanofilters as a platform for viral clearance studies for biotherapeutic applications.

1668 Oncolytic Adenovirus Armed with Multiple Immune Stimulatory Transgenes in Combination with PD-L1-Targeted Radioimmunotherapy Exert Synergistic Antitumor Effect Against Pancreatic Cancer

Chae-Ok Yun[1,2], A-Rum Yoon[2], Jeongwon Lee[2], Jea Hyun Seo[2]

[1]Gene-Medicine, Seoul, Korea, Republic of,[2]Hanyang University, Seoul, Korea, Republic of

Despite the remarkable advancements made in the immuno-oncology field, no immunotherapy regimen has been approved by US FDA for the treatment of pancreatic cancers to date. In detail, highly desmoplastic and immune-desert phenotype of pancreatic cancer are two major hurdles to the development of effective immunotherapy regimen, as these attributes markedly attenuate the capacity of cancer therapeutics and immune cells to penetrate and disperse throughout the tumor tissues to elicit robust antitumor immune response. To overcome these hurdles and develop an effective immunotherapy regimen against pancreatic cancer, a novel hypoxia-responsive oncolytic Ad (HY-oAd) co-expressing single-chain interleukin-12 (scIL12), granulocyte macrophage colony stimulating factor (GMCSF), and relaxin (RLX) and PD-L1-targeted immune checkpoint inhibitor (ICI), atezolizumab, radiolabeled with lutetium-177 (Lu-177; aPD-L1-Lu) were developed and their combined therapeutic efficacy was evaluated in desmoplastic and poorly immunogenic Pan02 syngeneic pancreatic tumor model. HY-oAd induced all three therapeutic genes in a dose-dependent and hypoxia-responsive manner in both human and murine pancreatic cancer cell lines. Importantly, HY-oAd treatment was shown to elevate PD-L1 expression level and promoted degradation of extracellular matrix (ECM) of pancreatic tumors, which led to elevated aPD-L1-Lu uptake. HY-oAd and aPD-L1 ICI therapy elicited more potent antitumor effect against the primary tumors than respective monotherapy in subcutaneous pancreatic tumor model due to enhanced infiltration and activation of $CD8^+$ T cells and significant attenuation of immunosuppressive regulatory T cells (Tregs). In an orthotopic pancreatic tumor model, HY-oAd and aPD-L1 ICI combination therapy showed superior antitumor efficacy against both the primary and metastatic tumors compared with monotherapy regimens. Importantly, the therapeutic effect of HY-oAd and aPD-L1-Lu was further augmented by addition of locoregional radiotherapy, which led to superior tumor growth inhibition and survival rate compared to HY-oAd and aPD-L1-Lu without radiation in both subcutaneous and orthotopic pancreatic tumor models. Collectively, our findings demonstrate that HY-oAd can enhance intratumoral accumulation of aPD-L1-Lu in a multifaceted manner to elicit synergistic antitumor immune response against desmoplastic and poorly immunogenic pancreatic tumors.

1669 Immune Synapse Optimized GRP78-Specific CAR T Cells Elicit an Improved Antitumor Response Against DIPGs

Jorge Andres Ibanez[1], Haley Houke[1], Michaela Meehl[2], Sanya Mehta[2], Meghan Dukes[1], Unmesha Thanekar[2], Nikhil Hebbar[3], Paulina Velasquez[1], Giedre Krenciute[1]

[1]Bone Marrow Transplantation and Cellular Therapy, St. Jude Children's Research Hospital, Memphis, TN,[2]Bone Marrow Transplantation and Cellular Therapy, St Jude Children's Research Hospital, Memphis, TN,[3]St. Jude Children's Research Hospital, Memphis, TN

Diffuse intrinsic pontine gliomas (DIPGs) are highly lethal pediatric brain tumors and a leading cause of cancer-related deaths in children. There is currently no cure for DIPG, highlighting an urgent need for novel therapeutics. Chimeric antigen receptor (CAR)-engineered T-cell therapy offers great promise for DIPG treatment; however, several limitations need to be addressed. In this study, we targeted a novel tumor associated antigen GRP78 because we showed it is reliably expressed on DIPGs. To test the anti-DIPG activity of GRP78-CAR T cells, we evaluated cytotoxicity, persistence, and cytokine secretion *in vitro*. We found that GRP78-CAR T cells kill DIPGs but fail to proliferate and secrete cytokines compared to positive control, U87. *In vivo* studies further confirmed that GRP78-CAR T cells eradicated U87 tumors but not DIPGs. Based on these findings, we concluded that DIPGs cannot trigger efficient CAR T cell signaling. Because CAR T

cell effector function is influenced by antigen density, we quantified the relative GRP78 expression on DIPGs and other brain tumors, including U87. We found that GRP78 is comparatively lowly expressed on DIPGs. Live-cell imaging of calcium flux in CAR T cells further revealed that T cell activation is lower upon interaction with DIPGs than U87s, suggesting that CAR-T cells form incomplete or dysfunctional immune synapses (IS) against DIPGs. To improve IS function, we knocked-out RASA2, a TCR downstream signaling inhibitor. Our results show that T cells that lack RASA2 have an improved IS reflected by bigger synaptic areas, increased lytic granules, and pZAP70 accumulation at the synapse. RASA2 KO further increased calcium influx and proliferation capacity of GRP78-CAR T cells against DIPGs. Thus, this study confirms that antigen density controls CAR T cell antitumor activity and improving the IS formation of CAR T cells elicits enhanced antitumor response against low antigen-expressing tumor cells.

1670 A Quantitative Method for Evaluating AAV-Mediated FKRP Expression and Function in Differentiated Myotubes

Jenny D. Herndon[1], Liang Zhou[1], Taylor S. Ralph[1], Kayla M. Shumate[1], Blanca Lopez de Juan Abad[1], SiewHui Low[2], Xiaodong S. Fang[1]

[1]Translational Medicine, Asklepios BioPharmaceutical, Inc. (AskBio), Durham, NC,[2]Clinical Development, Asklepios BioPharmaceutical, Inc. (AskBio), Durham, NC

Certain mutations in the fukutin-related protein (FKRP) gene prevent correct glycosylation of the structural protein α-dystroglycan (a-DG), leading to Limb-girdle Muscular Dystrophy 2I (LGMD2I/R9). Western blot and immunohistochemistry (IHC) analysis of muscle biopsies, whether for the detection of vector delivered WT FKRP protein or glycosylated a-DG using a monoclonal IIH6 antibody, have reliably confirmed expression of FKRP and correct glycosylation of its biological target in both research and diagnostic settings. However, development of robust in vitro assays which accurately measure both the expression of vector delivered FKRP and its downstream biomarkers remain an important objective in the field. There are technical challenges in the cultivation and transduction of differentiated myotubules, as well as the accurate quantification of glycosylated a-DG. Complete glycosylation of a-DG is not reached in cell culture models and a heterogeneous mix of different glycosylation states depending on stage of differentiation is often the result, which can obscure consistent quantitative measurements. We have developed a novel cell-based assay using immortalized myoblasts to assess the viability of adeno associated virus (AAV) vector gene delivery of FKRP. Important assay parameters were characterized to achieve maximum transgene expression/detection and target specificity. The downstream biological effect of FKRP expression, a-DG glycosylation, was quantitatively measured in a dose response using a plate-based ligand binding assay, which provides both high throughput and reliable quantitation of this downstream biomarker. This research may support the use of a single quantitative assay to characterize both transgene expression and its biologic function.

1671 Engineering Human Hematopoietic Stem and Progenitor Cells for Lineage-Specific Expression of Galactocerebrosidase Using Genome Editing

Nelson A. Amorin[1], Lexi-Ann Golden[1], Edina Poletto[2], Nicole Marie Johnston[3], William Feist[3], Talia Menezes[1], Karen Kikuta[1], Sofia Elena Luna[4], Celia Charlton[1], Tyler Kashuv[1], Natalia Gomez-Ospina[5]

[1]Pediatrics, Stanford University, Stanford, CA,[2]Stanford, Stanford, CA,[3]Stanford University, Stanford, CA,[4]Stanford, Menlo Park, CA,[5]Stanford, Palo Alto, CA

Krabbe disease is a lysosomal storage disease caused by a deficiency in Galactocerebrosidase (GALCase) that affects the central and peripheral nervous system. Typically, symptoms are early onset and result in aggressive neurological deterioration with death in early childhood. The only available treatment is allogeneic hematopoietic stem cell transplant (allo-HSCT) which has significant morbidity and mortality, restricting its use to asymptomatic individuals with available donors. A potentially safer, more effective therapy for Krabbe disease might be achieved by engineering the patient's own hematopoietic system and consequently the monocyte/macrophage lineage to produce GALCase expressed at supra-physiological levels. This results in enhanced biochemical cross-correction, decreased morbidity, and eliminates the need for matched donors. Here we report an efficient CRISPR/Cas9 and AAV6-based approach that targets GALCase expression cassette with a monocyte/macrophage specific promoter to the CCR5 safe-harbor locus in human hematopoietic stem and progenitor cells (HSPCs). AAV donor repair templates were generated to drive GALCase expression with a lineage-specific promoter. This expression derived from CD68 promoter is restricted to the monocyte/macrophage lineage. This promoter was chosen to minimize potential complication of GALCase overexpression in the stem cell compartment. The allele targeting frequency of the CD68-GALCase vector was 29.75% and is sustained for 21-days in culture. The targeted cells generate about 1.5-fold increased galactocerebrosidase expression in macrophages and maintain multilineage differentiation potential in-vitro. By using a safe-harbor locus and lineage specific promoter to express GALCase, we minimize the risk of cytotoxicity in the stem cell compartment. Transplantation experiment into a immunocompromised mouse model will be required to determine GALCase HSPCs ability to maintain stemness and differentiation potential in-vivo. If further studies prove successful, the next step involves correcting Krabbe disease in a mouse model.

1672 Triaging Detergent Lysis for Downstream Purification of Recombinant Adeno-Associated Virus through Analytical Characterization, to Maximize Processing Yields

Srivanya Tummala, Khan Umaer, Ngan Trinh, Kelly Geosits, Marguerite Campbell, Brian Tomkowicz

Viral Vector Research & Development, Center for Breakthrough Medicines, King Of Prussia, PA

The prevalence of AAV for use in gene therapies has brought about an increase demand for manufacturing. In so doing, the importance of

process improvement to lower manufacturing costs, improved process efficiencies, and increase production yields and purity is imperative. While there are many opportunities to reduce step losses at each phase of the manufacturing process none are more critical than at viral harvest from cells. The efficient release of virus from cells during recombinant vector production, if not done appropriately, can result in >50% loss in product due to inefficient lysis or precipitation/aggregation awaiting purification. To address this, we screened a panel of lysis reagents that are amenable for use in single step lysis of production cultures. As part of this panel, we included commercially available reagents, along with various detergents and salt combinations for a simplified single-step process and faster purification. Using our optimize purification methods of AKTA-based affinity chromatography, hydrophobic interaction chromatography and anion exchange chromatography, we demonstrate how lysis conditions directly impact viral recovery and analytical characterization to measure viral capsid titer, genome content, empty/ full ratio, capsid stoichiometry, host cell proteins and DNA content. This information should serve as a guide for improved downstream process controls the yield of recombinant AAV particles.

1673 Exploring Upstream Process Conditions to Improve Productivity of Novel AAV Capsids

Hari Acharya[1], Heidy Morales[1], Jesse Granados[2], Elissa Troisi[1], Lysa-Anne Volpe[1]

[1]Process Development, Capsida Biotherapeutics, Thousand Oaks, CA,[2]Analytical Development, Capsida, Thousand Oaks, CA

Recombinant adeno-associated virus (rAAV) has emerged as a promising technology for the delivery of gene therapies. There are multiple approved treatments and numerous (>100) ongoing clinical trials using wildtype serotypes. The rAAV field has focused on rare diseases because of the unmet medical needs of patients, the mechanism for correction (i.e., repair of a monogenic defect), and the amounts of material needed. As novel capsids with improved tissue tropism, better transduction efficiency, and reduced toxicity are developed, opportunities to treat larger patient populations and prevalent indications arise. To this end, scalable, higher-producing processes are needed to meet the material demands and, as the field matures, to help reduce costs. Suspension-based processes are more amenable to scale-up and are the basis for the work presented. Using HEK293 cells in suspension and a triple transfection process, bioreactor operating parameters and plasmid designs are tested. Bioreactors can support higher cell densities and allow greater parameter control compared to incubators and shaker flasks. Conditions are identified that improve titer and reduce residual impurity levels. The optimized bioreactor conditions are tested with multiple novel capsids to assess process robustness. Upstream changes potentially impact downstream steps. We look at harvest filter train sizing as part of assessing bioreactor changes. Collectively, the work here shows bioreactor conditions can be optimized to improve titer and process robustness for novel capsids identified from the platform.

1674 TAPE-seq is a Cell-Based Method for Predicting Genome-Wide Off-Target Effects of Prime Editor

Jungjoon Lee, Jeonghun Kwon, Minyoung Kim, Seungmin Bae, Anna Jo, Youngho Kim

Toolgen, Seoul, Korea, Republic of

Prime editors (PEs) are powerful tools that widen the possibilities for sequence modifications during genome editing. Although methods based on the analysis of Cas9 nuclease or nickase activity have been used to predict genome-wide off-target activities of PEs, no tool that directly uses PEs for this purpose has been reported yet. In this study, we present a cell-based assay, named TAgmentation of Prime Editor sequencing (TAPE-seq), that provides genome-wide off-target candidates for PEs. TAPE-seq analyses are successfully performed using many different versions of PEs. The TAPE-seq predictions are compared with results from two other off-site prediction methods, Cas9 nuclease-based GUIDE-seq and Cas9 nickase-based Digenome-seq (nDigenome-seq). TAPE-seq shows a lower miss rate, and a higher area under the receiver operating characteristic curve compared to the other methods. TAPE-seq also identified valid off-target sites that were missed by the other methods.

1675 *TRAC*-Knock-In CD19CAR-T or gp350CAR-T Cells Targeting Burkitt Lymphoma with Type 1 or 2 EBV Infections Show Variable Potency, CD4/CD8 Ratios and Exhaustion Patterns

Renata Stripecke[1], Tobias Braun[2], Alina Pruene[2], Milita Darguzyte[1], Alexander vom Stein[1], Phuon-Hien Nguyen[1], Dimitrios L. Wagner[3]

[1]Department I of Internal Medicine, University of Cologne, Faculty of Medicine and University Hospital Cologne, Cologne, Germany,[2]Hannover Medical School, Hannover, Germany,[3]Charité Universitaetsmedizin Berlin, Berlin, Germany

INTRODUCTION: The ubiquitous Epstein-Barr virus (EBV) is an oncogenic herpes virus and is associated with several human malignancies. EBV is a notorious immune evasive pathogen that promotes $CD8^+$ T cell exhaustion and modulates $CD4^+$ T cell functions. Burkitt lymphoma (BL) is frequently associated with EBV latent infections, yet some cell lines show surface expression of the lytic antigen gp350. BL patients after relapse could profit from CAR-T cell therapy targeting cellular or EBV antigens. METHODS: We evaluated and compared the effects of CD19CAR.CD28z-T and gp350CAR.CD28z-T cells against $gp350^+$ $CD19^+$ BL. We used CRISPR/Cas9 methods to knock-in (KI) the CD19CAR.CD28z or gp350CAR.CD28z into the T cell receptor (TCR) alpha chain (*TRAC*) locus. RESULTS: For both CARs, the KI efficacy was roughly 20%. ^{KI}CAR-T cells were co-cultured *in vitro* with $gp350^+$ $CD19^+$ BL cell lines Daudi (type 1, generally latent EBV) or with Jiyoye (type 2, generally lytic EBV). Both types of CAR-T cells caused cytotoxic effects against BL lines *in vitro*, and the frequencies of $^{KI}CD8^+$ CAR-T cells at the end of the cultures were higher than $^{KI}CD4^+$ CAR-T cells. Co-culture of $CD19^{KI}$CAR-T cells with both BL lines showed upregulation of the activation / exhaustion markers PD-1, LAG-3 and TIM-3. For $gp350^{KI}$CAR-T cells, only Jiyoye

caused upregulation of the exhaustion markers. Two preclinical *in vivo* xenograft models were set up with NRG mice injected i.v. with $2x10^5$ Daudi/fLuc-GFP or Jiyoye/fLuc-GFP cells. Compared with the non-treated controls, mice challenged with either BL type and treated with $CD19^{KI}$CAR-T cells showed delayed lymphoma dissemination and lowered EBV DNA load. Administration of $gp350^{KI}$CAR-T cells into mice did not inhibit BL growth *in vivo*, but reduced the EBV DNA load of Jiyoye/GFPfLuc in bone marrow. Notably, $CD8^+$ $gp350^{KI}$CAR-T cells and $CD4^+$ $CD19^{KI}$CAR-T cells accumulated in the Jiyoye model. CONCLUSIONS: The type of CAR and the nature of the EBV^+ malignancy may contribute to different mechanisms of T cell development and therapeutic outcomes. Since CAR-T cells are being used clinically against lymphomas that carry latent or lytic EBV, it is important to take into account that EBV's immune escape mechanisms may interfere with the CAR-T cell properties and potency.

1676 Application of CRISPR Genome Editing to a Mouse Model of DFNA20/26

Zeynep Ozgur[1], Samantha C. Lau[1], Mhamed Grati[1], Kevin Isgrig[1], Jianliang Zhu[1], Hong Jun Wang[1], Yasuko Ishibashi[1], Meghan Drummond[2], Inna Belyantseva[2], Karen Friderici[3], Thomas B. Friedman[2], Wade W. Chien[1,4]

[1]Inner Ear Gene Therapy Program, National Institute on Deafness and Other Communication Disorders, National Institutes of Health, Bethesda, MD,[2]Laboratory of Molecular Genetics, National Institute on Deafness and Other Communication Disorders, National Institutes of Health, Bethesda, MD,[3]Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI,[4]Department of Otolaryngology-Head and Neck Surgery, Johns Hopkins School of Medicine, Baltimore, MD

Sensorineural hearing loss is a common disorder which affects the world's population. Previous inner ear gene therapy studies have shown promising results in improving auditory function in various mouse models of sensorineural hearing loss. While many studies focus on non-syndromic autosomal recessive hereditary hearing loss (DFNB), non-syndromic autosomal dominant hereditary hearing loss (DFNA) may be a better candidate for inner ear gene therapy translation due to the later onset and slower progression of hearing loss, which offers a wider therapeutic window for treatment. In this study, we applied CRISPR genome editing to a mouse model of human DFNA20/26. DFNA20/26 is caused by mutations in the *ACTG1* gene, which encodes gamma actin, an isoform of actin that is abundant in the inner ear. The $Actg1^{P264L/P264L}$ mutant mouse has an orthologous human P264L knock-in mutation and develops progressive hearing loss starting at ~P30 due to outer and inner hair cell stereocilia bundle abnormalities. In this study, guide RNAs (gRNAs) were designed and validated to target the P264L mutation *in vitro*. The gRNA with the best sensitivity and specificity for targeting the P264L mutation was delivered via adeno-associated virus (AAV) along with Cas9 nuclease into neonatal $Actg1^{P264L/P264L}$ inner ears via the posterior semicircular canal approach. We found that $Actg1^{P264L/P264L}$ mutant mice that were treated with CRISPR gene therapy showed improved outer hair cell stereocilia morphology compared to the untreated mutant mice. In addition, treated $Actg1^{P264L/P264L}$ mice showed improved ABR thresholds at ~P30 compared to untreated mutant mice. Our results demonstrated that CRISPR genome editing was able to improve the stereocilia morphology and auditory function in $Actg1^{P264L/P264L}$ mice.

1677 The Essential Role of K^+ and Ca^{2+} for Maintaining Cytotoxic Activity of Cryopreserved GAIA-102, a Newly Developed Activated NK-Like Cells

Yufu Xin, Yui Harada, Ken-Ichi Wada, Yosuke Morodomi, Yoshikazu Yonemitsu

R&D Laboratory for Innovative Biotherapeutics, Faculty of Pharmaceutical Sciences, Kyushu University, Fukuoka, Japan

Background: Previously, we established an original method to generate highly activated NK-like cells (GAIA-102) from mixed peripheral blood mononuclear cells from multiple donors. Now three phase I clinical trials, including neuroblastoma, for assessing the safety and potential anti-tumor activity are on-going. Before moving clinical trials, we and others demonstrated that cryopreservation of NK-based therapeutic modalities, including GAIA-102, impaired their viability and cytotoxicity. To solve this critical issue for off-the-shelf practice, we discovered that Plasma-Lyte A (PLA; a clinically available drip infusion) is a good candidate for maintaining viability and cytotoxicity of GAIA-102. We speculated that the substances contained in PLA have a protective effect on cryopreserved GAIA-102, and that other substances may have the similar function, even better. The aim of this study is to identify the substances which provide the protective effects on cryopreserved GAIA-102 cells.**Methods:** After generating GAIA-102, they were cryopreserved using STEM-CELLBANKER® EX and stored at -80℃ for more than 2 days, then used for following experiments. Immediately after thawing, the GAIA-102 were incubated with the test drip infusions, then, the cell viability and cytotoxicity were assessed. KCl, $MgCl_2$, $CH_3COO{\cdot}Na$ or $C_6H_{11}O_7{\cdot}Na$ was tested. Bumetanide (Na-K-Cl cotransporter inhibitor), digitoxin (Na^+-K^+ pump inhibitor) or verapamil (Na^+-K^+ pump and calcium channel inhibitor) was added to PLA.**Results:** At first, various clinically available drip infusions have been tested, and found that incubation of GAIA-102 with the drip infusions containing Ca^{2+} or glucose resulted in lower viability compared to that with PLA, while Ca^{2+}-/glucose-free drip infusions did not. The cytotoxic activity of GAIA-102 was decreased by depletion of K^+ or acetate from PLA, and it was increased by addition of these to saline. However, the viability was not affected by depletion of any substances tested from PLA. In these experiments, the greater effect on viability and cytotoxicity was observed in Ca^{2+} and K^+ containing drip infusions, respectively, therefore, we subsequently focused on these ions. Supplementation of K^+ to saline increased cytotoxicity at 1 mEq/L but subsequent addition up to 50 mEq/L did not induce further increase without any effect on viability of GAIA-102. When 0-32 mEq/L Ca^{2+} was added to PLA, viability was getting lower in Ca^{2+} concentration-dependent manner, however, cytotoxic activity was not, suggesting that incubation with Ca^{2+}-containing drip infusions would increase the cytotoxic activity of each GAIA-102 cell. To evaluate the effect of K^+ and Ca^{2+} uptake, GAIA-102 were incubated with PLA supplemented with K^+ or Ca^{2+} channel inhibitors, demonstrated that any inhibitors tested did not affect cell viability. On the other hand, verapamil decreased cytotoxicity in a concentration-dependent manner, while bumetanide

and digitoxin did not.**Conclusion**: Based on these results, we concluded that Ca^{2+} and K^{+} have an essential role for maintaining the cytotoxic activity of cryopreserved GAIA-102.

1678 Treatment of Infantile-Onset Pompe Disease in a Rat Model with Muscle-Directed AAV Gene Therapy

Miquel Garcia[1], Sergio Muñoz[1], Joan Bertolin[1], Veronica Jimenez[1], Maria Luisa Jaen[1], Anna Pujol[1], Laia Vilà[1], Victor Sacristan[1], Elena Barbon[2], Giuseppe Ronzitti[2], Jihad El Andari[3], Warut Tulalamba[4], Quang Hong Pham[5], Jesus Ruberte[6], Thierry C. Vandendriessche[4], Marinee K.L. Chuah[7], Dirk Grimm[3], Federico Mingozzi[2], Fatima Bosch[1]

[1]Center of Animal Biotechnology and Gene Therapy (CBATEG), Universitat Autonoma de Barcelona, Bellaterra, Spain,[2]INTEGRARE, GENETHON, Evry, France,[3]Heidelberg University Hospital, Heidelberg, Germany,[4]Free University of Brussels (VUB), Brussels, Belgium,[5]Free University of Brussels (VUB), Brusels, Belgium,[6]Department of Animal Health and Anatomy, School of Veterinary Medicine, Universitat Autonoma de Barcelona, Bellaterra, Spain,[7]Free University of Brussels, (VUB), Brussels, Belgium

Pompe disease (PD) is an autosomal recessive disorder caused by deficiency of the lysosomal enzyme acid α-glucosidase (GAA), which leads to progressive glycogen accumulation, resulting in severe myopathy with progressive muscle weakness. In the Infantile-Onset PD (IOPD), death generally occurs early in life due to a cardiorespiratory failure. There is no cure for PD. Here, using CRISPR/Cas9 technology, we have generated the first rat model recapitulating key features of human IOPD. This rat model was used to assess a muscle-directed gene therapy based on the highly myotropic adeno-associated viral vector capsid AAVMYO3 and an optimized muscle-specific promoter, leading to widespread Gaa expression only in skeletal and cardiac muscles. Treatment of young PD rats with AAVMYO3-Gaa vectors mediated long-term correction of glycogen storage, prevented severe skeletal and cardiac muscle pathology, increased grip strength and rescued survival. This study provides a rationale for future clinical translation of this approach to treat PD.

1679 Rapid and Agile AAV Production Technologies: Cell-Free DNA Synthesis from Minicircles and Novel Bioreactor for Continuous Secreted AAV Collection

Brian Davis, Erik Kvam, Lisa Lowery, Evelina Loghin, Chrystal Chadwick, Chris Morton, Wei Gao, John Nelson

GE Research- HealthCare, Niskayuna, NY

Transient DNA transfection is commonly used to produce AAV vectors. cGMP plasmid production carries a high production cost and time burden (months to produce) due to: 1) complex bacterial-based manufacturing processes including establishment of master and working cell banks, large-scale bacterial fermentation, purification to remove immunogenic and toxic bacterial components, and related quality control assays, and 2) backlogs at the relatively few certified cGMP plasmid production facilities. This in turn can delay the advancement of gene therapy clinical trials. Thus, alternative methods that reduce cost, time and complexity are urgently needed, particularly for single patient production of AAV therapies for rare diseases. To address this issue, our group has been developing a cell-free synthesis approach to rapidly prepare DNA for cell transfection during AAV production. Our method produces gram quantities of rolling circle amplified (RCA) DNA from nanograms of circular templates in under one day. Cell-free production of RCA DNA uses defined buffer components, eliminating the need for host cell protein and endotoxin removal steps, and associated quality control assays. We have demonstrated that unprocessed, high molecular weight tandemly repeated RCA products can be used directly for transient transfection with high efficiency. We quantified AAV titers produced by triple-transfection of RCA DNA or plasmid DNA (encoding vector, rep/cap and adenoviral helper constructs) into suspension HEK293T cells, at up to 6 million cells per ml and up to 400 ml transfection volumes. Our data demonstrate that RCA DNA transfection produces ssAAV and scAAV with similar physical and biological titers as plasmid transfection. RCA DNA synthesized from minicircle DNA templates encoding the vector but lacking plasmid maintenance elements (e.g., antibiotic resistance genes) minimizes the risk of horizontal gene transfer of plasmid backbone elements into patients. We found that scAAV and ssAAV produced from plasmid, or from RCA DNA synthesized from plasmid templates, had a plasmid backbone sequence mispackaging frequency of ~20%. In contrast, RCA DNA synthesized from minicircle templates encoding the vector sequence had >10-fold lower mispackaging frequency. In parallel, we are developing a novel prototype single-use static perfusion bioreactor (SPB) for continuous secreted AAV collection from high density producer cells. The 300 cm^2 SPB supports cell densities up to ~$20x10^6$ cells/cm^2. Our initial evaluations tested the 300 cm^2 SPB using suspension HEK293T cells seeded at 3-$5x10^6$ per cm^2. The SPB enabled recovery of secreted AAV for 7 or more days post-transfection, with raw titers of ~10^{10} vg/ml. At the conclusion of a 7-day secreted AAV collection, the day 10 cell lysate still provided ~10^{13} vg. We are continuing to refine collection conditions. AAV titers from the SPB were comparable to titers obtained using the Xuri™ Cell Expansion System W25 (wave motion bioreactor). The raw secreted AAV collections were concentrated and purified using AAV-X affinity capture resins, providing ~90-100% recovery with a ~1000-fold reduction of total host cell protein content. In conclusion, the combination of these novel technologies may benefit personalized and agile AAV vector production for rare diseases for one to a few patients at a time.

1680 Zinc Finger Repressors Against Immune Checkpoint Molecules to Improve Anti-Tumor Activity of Gene-Modified T Cells

Davide Monteferrario[1], Marion David[1], Phillip Schiele[2], Yuanyue Zhou[3], Satish Tadi[1], Coralie Dupont[1], Caroline Jeanneau[1], Gaelle Saviane[1], Irene Marchetti[1], Angelique Martelli[1], Jason D. [1]Sangamo Therapeutics France, Valbonne, France,[2]BIH Center for Regenerative Therapies (BCRT), Berlin Institute of Health at Charité - Universitätsmedizin Berlin, Berlin, Germany,[3]Sangamo Therapeutics Inc., Richmond, CA

The adoptive transfer of gene-modified T cells has emerged as a revolutionary new pillar in cancer therapy owing to the unprecedented clinical results obtained with chimeric antigen receptor (CAR) T cells in treating certain subsets of B cell leukemia and lymphoma. Despite this remarkable success, many barriers still limit a more broadened therapeutic efficacy in solid tumors and other hematological malignancies. These include severe toxicities, antigen escape, restricted trafficking, and limited tumor infiltration. In addition, T cell exhaustion and an immunosuppressive tumor microenvironment (TME) represent critical constraints to maintain effector functions and persistence and achieve a durable clinical potency. To overcome these significant challenges, innovative strategies and approaches are necessary to engineer more potent gene-modified T cells with improved anti-tumor activity. We recently described the generation of highly specific Zinc Finger Repressors (ZF-Rs) capable of silencing gene expression in T cells without the need for double-strand breaks. Their degree of gene repression is tunable, ranging from a partial knockdown to total gene silencing. Furthermore, their compact size allows the multiplexing of ZF-R sequences in a single lentiviral vector (LV) to achieve concomitant multi-gene silencing upon a single transduction event. Using this technology, primary human T cells were engineered with a bidirectional LV construct encoding one or two ZF-Rs, either with or without an anti-CD19-CAR, to knock down cell surface proteins described as negative regulators of the anti-tumor activity. These include immune checkpoints, successfully targeted by immunotherapy, and also factors playing a key role in the TME and the TCR signaling. We demonstrated that our ZF-R-expressing LVs could efficiently transduce both PBMC-derived CD3+ cells and tumor-infiltrating lymphocytes isolated from colorectal cancer patients. ZF-Rs repressed the target genes with high specificity at the mRNA level, resulting in efficient protein repression and this gene silencing was highly stable over time. Significantly, expression of ZF-R proteins did not affect *in vitro* functionality of gene-modified T cells, warranting further evaluation of their anti-tumor activity in animal models. Overall, our study proposes an innovative cell engineering platform to deliver gene-modified T cells with an improved tumor-eradicating potential.

1681 Assessing Gene Therapy Application in a Mouse Model of PTEN Hamartoma Tumour Syndrome

Ceren Erdem, Sophie Thomson, Noha Bahey, Jim Selfridge, Stuart Cobb, Kamal Gadalla

Centre for Discovery Brain Sciences (CDBS), University of Edinburgh, Edinburgh, United Kingdom

PTEN Hamartoma Tumour Syndrome (PHTS) is an autosomal dominant disorder that is caused by germline mutations in the *PTEN* gene. PHTS is characterized by the development of multiple hamartomas as well as neurodevelopmental disabilities and autism spectrum disorder (ASD). The main function of PTEN is to regulate the PI3K/ AKT/mTOR signalling pathway which controls cell growth, proliferation, and survival. In the absence of effective treatment, continuous lifelong cancer surveillance and screening are critical for PHTS patients to allow early tumour discovery and treatment. PHTS is considered a good candidate for gene therapy due to the monogenic nature of the disorder and the lack of existing effective treatment. In addition, the *PTEN* coding can be readily packaged in AAV and the gene product may be secreted which could increase efficacy through cross-correction. Mouse models of PTEN haploinsufficiency show subtle neurological phenotypes but recapitulate other features associated with PTEN deficiency such as the development of multiple tumours, macrocephaly, and liver steatosis. In this study, we assessed the potential for gene therapy in preventing or ameliorating PHTS-like phenotypes in mice modelling *PTEN* haploinsufficiency. A codon optimized human PTEN transgene cassette was packaged in AAV9 and was injected systemically by tail vein injection into 5 weeks old $Pten^{+/\Delta 5}$ heterozygous female mice. A moderate dose (2.5×10^{13} vg/kg), and high dose (1×10^{14} vg/kg) groups were enrolled into the trial as well as cohorts of wild type and $Pten^{+/\Delta 5}$ mice were injected with vehicle (PBS) as controls. Experimental mice were monitored in a blinded fashion for the development and progression of gross/palpable tumours for 9 months. After mice were sacrificed, various tissues were collected for histopathological analysis. Our results show that 100% of $Pten^{+/\Delta 5}$ heterozygous mice, regardless of the treatment or the given dose, developed lymph node tumours with no treatment effect on the onset of tumour detection or tumour size. The lack of efficacy on tumour development could be explained by the very low virus copy number and the lack of detectable vector-derived PTEN expression in the lymph node tissue. In contrast, systemic injection of AAV9/*PTEN* increased PTEN level in the liver of vector-treated $Pten^{+/\Delta 5}$ heterozygous mice and significantly reduced the severity of liver steatosis (pre-cancerous lesion) and the monocytic infiltration observed in the vehicle-treated $Pten^{+/\Delta 5}$ mice. This study was limited by the fact that this mouse model develops gross tumours predominantly in the lymph nodes which are not efficiently targeted by AAV9. Development of a new capsid with higher lymph node tropism or crossing $Pten^{+/\Delta 5}$ mice with mice prone to hepatocellular carcinoma would be ideal to test the potential therapeutic effect of vector-derived PTEN on tumour development and progression.

1682 Safe and Effective Non-Viral Method for Delivering mRNA to the Lung Endothelium of Newborn Mice

David A. Eaton[1], Anna Y. Lynn[1], Madalina Ene[1], Hee-Won Suh[1], Alexandra Piotrowski-Daspit[1], David H. Stitelman[2], Peter M. Glazer[3], W. Mark Saltzman[1]

[1]Biomedical Engineering, Yale University, New Haven, CT,[2]Surgery, Yale University School of Medicine, New Haven, CT,[3]Therapeutic Radiology, Yale University School of Medicine, New Haven, CT

There have been rapid advances in the discovery and engineering of gene editing tools for monogenetic diseases in recent years. For the successful clinical translation of these therapies, there remains a need for safe and effective delivery vehicles. Poly(amine-co-ester) s (PACE) are cationic polymers with tunable chemistry that are capable of forming complexes with nucleic acids (i.e., polyplexes).[1] Various amine-containing groups can be conjugated to the end groups of the PACE chains to enhance endosomal escape.[2] PACE with an aminomethyl propanol end-group (denoted PACE-14) forms stable polyplexes that enable robust expression of mRNA in the lung epithelium after intratracheal administration.[3] We optimized PACE-14/mRNA polyplexes for intravenous (IV) use in the neonatal period as gene therapy at this developmental stage can prevent irreversible pathologies and access unique cell progenitor populations.[4] In this work, we demonstrate that the administration of PACE-14/mRNA polyplexes to newborn mice leads to mRNA expression in the lung endothelium without off-target expression in the liver or spleen. We formulated polyplexes encapsulating 0.25 μg of mRNA encoding for Cre recombinase and delivered the polyplexes via facial vein injection to Ai14 mice on postnatal day 1. Upon successful mRNA translation and subsequent Cre-mediated recombination, cells in the Ai14 mouse expressed robust TdTomato fluorescence. At 72 hr post-injection, we measured fluorescence in the lung, liver, and spleen by flow cytometry. We observed no TdTomato signal in the livers or spleens. In the lungs, we found approximately 55% of CD31+ endothelial cells expressed TdTomato. There was no expression in CD45+ lung cells or EpCAM+ lung cells. We confirmed these results by confocal microscopy of fixed lung tissue from uninjected and injected neonatal mice (Figure 1). None of the mice in either group exhibited gross signs of toxicity with the injection of the polyplexes. The use of PACE-14 polyplexes represents a safe and effective strategy for delivering mRNA to the lung endothelium of newborn mice. We hypothesize that IV administration of these engineered polyplexes will offer targeted delivery of gene-editing tools, such as Cas9 mRNA and sgRNA, to treat diseases of the pulmonary vasculature. One such disease is alveolar capillary dysplasia with misalignment of pulmonary veins (ACDMPV).[5] This congenital disorder leads to pulmonary hypertension after birth and early death and is associated with mutations in the Forkhead Box F1 (FOXF1) gene.[6] We believe the PACE-14 technology can be used to deliver gene-editing tools to correct the associated mutations in ACDMPV and prevent pulmonary hypertension in these neonates.

Figure 1. Images of neonatal lung without injection of mRNA (left) and with intravenous injection of PACE-14/Cre mRNA polyplexes (right)

1683 Mobilization-Based Chemotherapy-Free Conditioning for Hematopoietic Stem and Progenitor Cells Gene Therapy in the Non-Human Primate Model

Gabriele Pedrazzani[1,2,3], Attya Omer Javed[1,3], Stefan Radtke[4], Luisa Albano[1], Emily S. Fields[4], Sherash Ghaus[1], Jason David Murray[4], Daniele Canarutto[1,2], Greta E. N. Kanestrom[4], Hans-Peter Kiem[4], Luigi M. Naldini[1,2]

[1]San Raffaele Telethon Institute for Gene Therapy, Milan, Italy,[2]Vita-Salute San Raffaele University, Milan, Italy,[3]These authors contributed equally, -, Italy,[4]Fred Hutchinson Cancer Research Center, Seattle, WA

In conventional hematopoietic stem and progenitor cell (HSPC) gene therapy, the patient receives *ex vivo* genetically corrected HSPCs after conditioning regimens designed to reduce the number of resident cells in the bone marrow (BM) and free space for the engraftment of corrected ones. However, the chemo/radiotherapy-based conditioning procedures currently used in clinics may have severe acute and long-term side effects. To overcome this limitation and advance toward a chemotherapy-free non-genotoxic conditioning regimen, we previously reported that HSPC mobilization with G-CSF, AMD3100, and BIO5192, efficiently depletes the BM niche, creating a window of opportunity for the engraftment of *ex vivo*-cultured cells in a human hematochimeric mouse model. Additionally, transient overexpression of the CXCR4 homing receptor using an improved mRNA platform, showed the compatibility with gene transfer and CRISPR/Cas9-based homology mediated gene editing, conferring to the transplanted cells a competitive engraftment advantage over the mobilized recipient ones. Here, we explored the application of CXCR4 variants resistant to their antagonist AMD3100 used for mobilization to further increase the advantage of donor cells. mRNA-based transient overexpression of these variants on the cell surface endowed human HSPCs with partial resistance to CXCR4 antagonists both in *in vitro* migration assays and *in vivo.* In particular, we show that transplantation in hematochimeric mice of HSPCs overexpressing the drug-resistant CXCR4 variant led to

enhanced exchange with the mobilized recipient cells when compared to overexpression of wild type CXCR4. Moreover, transient overexpression of other homing and retention receptors, as KIT, ITGA4, and the anti-phagocytosis signal CD47, are currently under investigation as they may provide a synergistic effect when coupled with CXCR4. However, the hematochimeric mouse model may not fully reproduce the human HSPC-niche interaction and testing and validation of our exchange strategy in non-human primates (NHP) is required before planning its clinical translation. Our current results in this model are consistent with observations in human cells, showing that CXCR4 expression is rescued during *ex vivo* culture of NHP HSPC harvested by G-CSF and AMD3100 mediated mobilization and transient overexpression of this molecule increases SDF-1 dependent migration efficiency in *in vitro* assays. Moreover, we show that base editing at the CD33 locus and CXCR4 overexpression can be combined without impacting the efficiency of each procedure, conferring edited cells a migration advantage. Successful translation in the NHP model of our strategy leveraging on HSPC mobilization and transient overexpression of drug-resistant CXCR4 may open the path toward a broader and safer clinical application of HSPC gene transfer and gene editing minimizing the toxicity associated with current conditioning procedures.

1684 Hybrid Dual scAAV Delivery of Transgenes to the Kidney

Jennifer L. Peek[1], Alan Rosales[2], Richard Welch[1], Thomas Beckermann[1], Lauren E. Woodard[1], Trevor J. Gonzalez[2], Aravind Asokan[2], Matthew H. Wilson[1]

[1]Vanderbilt University Medical Center, Nashville, TN,[2]Duke University, Durham, NC

Gene therapy for kidney disease remains a challenge primarily due to lack of gene delivery to the kidney. Cystinuria, the most common inherited kidney stone disorder, results from a deficiency of an amino acid transporter (rBAT) that reabsorbs cystine in proximal tubular cells. Cystinuria patients suffer from cystine stones, obstruction, and development of chronic kidney disease; current effective treatments are lacking for this lifelong disease. We have previously shown significant reductions in urinary cystine levels in murine models of type A cystinuria through plasmid delivery of transposable elements containing *Slc3a1*, which encodes rBAT. However, gene transfer was estimated to be 1-5% of proximal tubular epithelial cells within the injected kidney and therefore did not affect cystine stone formation. Recent innovations in viral vectors have allowed for improved renal transduction. With a novel adeno-associated virus, AAV.cc47, we have shown efficient viral delivery to the proximal tubule in mice. However, the proximal tubule-targeting AAV utilizes a reduced viral genomic packaging size due to self-complementary DNA. In order to design a gene therapy strategy for type A cystinuria using this AAV, the transgene packaging limitations of the AAV necessitate the splitting *Slc3a1* into two AAVs. Full length *Slc3a1* expression can be induced by recombination of the split *Slc3a1* transgene using hybrid homologous recombination and mRNA splicing within the host cell. We have validated this hybrid reconstitution strategy to express *Slc3a1* in *in vitro*, in human kidney organoids, and in *in vivo* models of type A cystinuria. Further characterization of the cystinuria phenotype is necessary to assess potency and long-term efficacy of the dual-AAV gene delivery of *Slc3a1* to type A cystinuria mice. Phenotypic correction of a kidney disease has remained a challenge in animal models, but our current efforts to optimize the delivery, integration, and stable expression of desired transgenes through AAV and transposon engineering provide hope for overcoming the barriers to kidney gene therapy.

1685 Simultaneous Delivery of Multiple AAV Vectors by Phenolic Adhesives

Yu Ri Nam[1], Zheng Rong Lau[2], Daiheon Lee[1], Jae-Hyung Jang[2], Haeshin Lee[1]

[1]Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of,[2]Yonsei University, Seoul, Korea, Republic of

Introduction Adhesive properties of polyphenolic molecules have been widely used in interdisciplinary fields such as biomedical and energy devices. When encountering biological macromolecules such as proteins, polyphenols exhibited rapid complexation with serum or cellular proteins controlling their binding affinities and activities. Adeno-Associated Virus (AAV)-based gene therapy products have been approved by US and EU FDAs. While AAV is safe for human, the DNA packaging is limited to ~4.7 kB (corresponding to ~1,600 amino acids) which is one of main limitations in AAV therapeutics. Thus, simultaneous delivery of AAVs to specific cells or tissues is utmost important to address the gene size limitation. In this study, we propose preparation of supramolecular AAV assembly by adhesive phenolic molecules for simultaneous delivery of multiple genes. **Methods** We chose one naturally exiting polyphenol and one non-natural polyphenol to prepare supramolecular AAV assembled particles. For supramolecular assembly, naturally existing polyphenol was mixed vigorously with AAVs at a volumetric ratio of 1:1 and 9:1 for non-natural polyphenol. Ultraviolet-visible (UV-Vis) spectroscopy was used to estimate the formation of supra-molecularly assembled AAVs. For further size analysis Atomic Force Microscopy (AFM) was used. To demonstrate the cellular uptake efficiency by supra-molecularly assembled AAV, HEK293T (Human Embryo Kidney) cell line was used. After 48-hour infection, fluorescent images were obtained using fluorescence microscopy and fluorescence-activated cell sorting (FACS) was conducted to quantify the values. **Results** The AAVs solutions assembled via natural and non-natural polyphenols showed a little turbidity. If the complex exhibited microscale aggregation, A600 was expected to increase because of light scattering. Furthermore, AFM imaging was conducted for size analysis of AAVs. The height of original AAV showed ~22 nm height which shows the similar value as many researchers reported (~ 25 nm). In contrast, the height of the particle was shown to be in the range of 100 - 250 nm for naturally existing polyphenol assembled AAVs. For non-natural phenolic assembly, a slight increased size distribution was observed. Our *in vitro* experiments revealed improved co-transduction efficiency of dual AAV vectors by 76-80 % compared with no assembled AAV treatments. **Conclusion** This study demonstrated that use of polyphenol molecules is a promising approach to assemble AAV particles. In principle, the gene number delivered by AAV vehicles is many, but in practice, co-delivery of two or three genes is reasonable gene numbers. Attempts to increase the number of genes remains further an on-going study.

1686 Novel Machine Learning Protocol for the Phenotypic Prediction of AAV Variants Library Production

Dylan Serillon[1], Tiziana La Bella[2], Jean-Philippe Buffet[1], Anastasia Barkova[1], Ante Mihaljevic[2], David Del Bourgo[1], Guiseppe Ronzitti[2], Julien Cottineau[1]

[1]WhiteLab Genomics, Paris, France,[2]INTEGRARE, Genethon, Evry, France

The last decades have seen the important development of informatics lead to a revolution in the study of complex biological processes. Applying artificial intelligence (AI) methods to existing biological datasets offers an innovative strategy to predict biological properties.[1] Machine learning and deep learning are evolving branches of computational algorithms that use mathematical and statistical approaches to emulate human intelligence, using the surrounding environment as a learning step. Adeno-associated virus (AAV)-based capsid libraries are growing popular as candidate selection tools for gene therapy vectors, underscored by recent advances in the study of the specific VR-VIII region.[2] However, available data on mutations outside this region remains severely unexplored. To optimize the biological properties of AAV and generate suitable data on these regions, AAV diversity was generated through shuffling of amino acid 353-601 of natural capsids. This shuffling of natural AAV allowed the creation of a specific library composed by 272 capsids, mutated in 43 different positions along the 249 bp region. A machine learning (ML) model was then built, based on the two following protocols: (i) Learning from the sequence, we generated numerical descriptors characterising the physico-chemical properties of the mutated residues. (ii) Based on the sequence, the AAV2 variants were partially reconstructed as 3D objects, and a ML algorithm was trained on the geometric data. The following figure summarises these protocols:

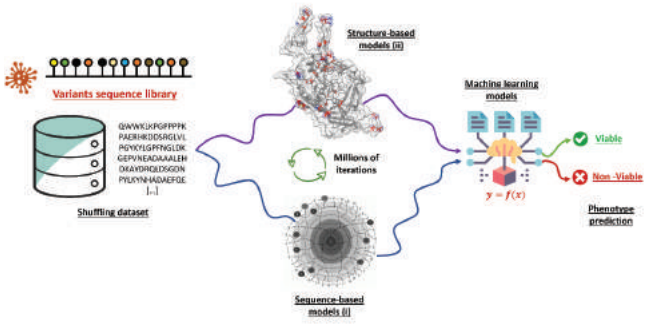

Figure: Schematic representation of the protocols used for the phenotypic prediction of AAV variants.

In total, more than a million models were generated through the variation of the tuning parameters, the cross-validation protocol, and different data partitions. Both models have different ways to predict the same output and achieve powerful performances: respectively (*i*) 100% accuracy, (*ii*) and 94% accuracy with associated specificity (66%) and sensibility (100%). In conclusion, experimentally produced shuffled AAV variants were successfully used to predict capsid viability for multiple mutations outside of the VR-VIII region. Our machine learning protocols result in powerful performances and lead to the identification of positions predicted as fundamental for the stability of the shuffled natural AAV capsid. As a perspective, additional experimental assessments will be performed on a selected list of variants mutated at the 43 positions identified as interesting by our AI protocols.

1687 Peptide-Mediated Delivery of CRISPR Ribonucleoprotein (RNP) into Primary Human CD34+ Hematopoietic Stem Cells

Madalena Castro

Innovative Genomics Institute, University of California, Berkeley, Berkeley, CA

Following mobilization, cultured hematopoietic Stem and Progenitor Cells (HSPCs) can be edited by CRISPR-Cas9 *ex vivo* for cell therapy. Autologous transplantation of edited HSPCs has already demonstrated clinical success in addressing monogenic blood disorders such as β-hemoglobinopathies. Efficient and gentle intracellular delivery of the CRISPR ribonucleoprotein (RNP) complex is a remaining challenge, since the predominant technology is electroporation, which has substantial drawbacks including poor cell viability and dramatic impacts on cell state (which may, in turn, impair cells' ability to engraft). Inspired by viruses, which rely on peptide sequences with cell-penetrating capacities to cross cell membranes, we have designed and tested a library of amphiphilic peptides with cell penetrating and endosomolytic capacities. When combined with different CRISPR enzymes: Cas9 nuclease, adenine base editor (ABE8e), and Cas12a (Cpf1), our novel peptides can deliver CRISPR RNP to the nucleus of primary human CD34+ HSPCs and perform efficient genome editing (up to 82% indels via NGS) while showing only limited toxicity (≤20% dead cells). Our delivery approach produces therapeutically relevant levels of editing using either nuclease or base editor, surpassing the clinical threshold (>20%) for therapeutic benefit of sickle cell disease patients (up to 60% and 55% editing at the *BCL11A* enhancer via Cas9 and ABE8e, respectively). This approach maintains cell viability, proliferation, and phenotype as well as their potential to differentiate and perform erythropoiesis. Our delivery technology involves applying the RNP-peptide complex directly to cells in suspension by simply mixing them into the culture, with no complicated manipulation or hardware requirements (for either synthesis or administration of the RNP-peptide formulation). Importantly, all components of our system can be readily manufactured: recombinant protein and synthetic RNA & peptide. Finding a reliable, efficient, gentle, convenient, and cost-effective delivery method is crucial to improve and deploy HSPC-based cell therapies, especially since β-hemoglobinopathies are most prevalent in developing countries. Our CRISPR delivery system is an appealing alternative to existing methodologies, and may facilitate a semi-automated, point-of-care manufacture pipeline for precision cell therapies.

1688 The Asparaginyl Hydroxylase FIH1 Improves Oncolytic Virotherapy in GBM

Karina Vazquez-Arreguin[1], Yoshihiro Otani[2], Kimberly Rivera-Caraballo[2], Pei Guangsheng[3], Zhongming Zhao[3], Balveen Kaur[1]

[1]Pathology, Georgia Cancer Center, Augusta University, Augusta, GA,[2]Neurosurgery, UTHealth, Houston, TX,[3]Center for Precision Health, School of Bioinformatics, UTHealth, Houston, TX

Glioblastoma (GBM) is the most common type of brain tumor in adults, and to this date remains a deadly disease with limited treatment options. Oncolytic viral therapy is emerging as a promising therapeutic strategy against notoriously resistant tumors, including GBM, for which there is now an oncolytic herpes simplex virus (oHSV) G47Δ, approved as a drug in Japan. The asparaginyl hydroxylase factor inhibiting HIF (FIH1) is located in chromosome 10q24, a region often deleted in GBM as an inhibitor of HIF1α-mediated transcription of VEGF-A, leading to decreased angiogenesis. We previously demonstrated targeting of FIH1 by a viral encoded miRNA in oHSV-infected GBM cells. In addition, our previous work shows that FIH1 negatively regulated oHSV-induced NOTCH signaling in GBM tumors. We have thus hypothesized that FIH1 reconstitution in tumors will block pro-tumorigenic NOTCH and HIF1α signaling. Using FIH1-overexpressing cells and a newly generated FIH1-expressing oHSV, we observed a reduction in vascular permeability, measured by intravital imaging, and decreased expression of angiogenesis markers. In vivo, combination of FIH1 overexpression with oHSV treatment resulted in enhanced survival in mice bearing intracranial GBM tumors. Furthermore, FIH1 overexpression correlated with the enrichment of genes associated with oxidative phosphorylation and ROS pathways, in addition to increased VEGF expression through a HIF1α-independent pathway, suggesting the potential for multi-modality therapeutic strategies.

1689 CAR-Tregs for Systemic Lupus Erythematosus

Matteo Doglio[1], Alessia Ugolini[1], Barbara Camisa[1], Cristiano Toma[1], Rossana Norata[2], Stefania Del Rosso[3], Fabio Ciceri[4], Francesca Sanvito[5], Monica Casucci[6], Angelo A. Manfredi[7], Chiara Bonini[8]

[1]Experimental Hematology, San Raffaele Scientific Institute, Milan, Italy,[2]GLP Test Facility, San Raffaele Telethon Institute for Gene Therapy (SR-Tiget), San Raffaele Scientific Institute, Milan, Italy,[3]Autoimmunity Lab, San Raffaele Hospital, Milan, Italy,[4]Hematology and Bone Marrow Transplantation Unit, San Raffaele Hospital, Milan, Italy,[5]Pathology Unit, Division of Experimental Oncology, San Raffaele Hospital, Milan, Italy,[6]Innovative Immunotherapies, San Raffaele Scientific Institute, Milan, Italy,[7]Autoimmunity and Vascular Inflammation Unit, San Raffaele Scientific Institute, Milan, Italy,[8]Università Vita Salute San Raffaele, Milan, Italy

Several common manifestations of Systemic Lupus Erythematosus (SLE) poorly respond to conventional medical treatments due to unstoppable immune-mediated tissue damage associated with altered architecture and function of the lymphoid organs. Hence the need for alternative strategies. A promising approach could focus on regulatory T lymphocytes (Tregs), which physiologically quench the autoimmune response and could promote tissue regeneration. Previous studies have shown that to be successful, Tregs must recognize relevant antigens, have limited off-target bystander effects and be safe. We describe here the results of a cell therapy strategy based on Tregs that overexpress FoxP3 and bear an anti-CD19 CAR (Fox19CAR-Tregs). They proved effective in vitro in restraining the activity of B cells, a key player in SLE, without unwanted pro-inflammatory action. In an ad hoc humanized mouse model of SLE, Fox19CAR-Tregs were extraordinarily effective, being able, despite a relatively short in vivo survival (14 days), to restrict autoantibody generation, to protect spleens, kidneys and lungs, to delay lymphopenia, a key feature of SLE, and to restore the composition of the human immune system in lymphoid organs, in absence of inflammatory effects or detectable toxicity.Therefore, a single infusion of Fox19CAR-Tregs is sufficient to break the vicious cycle that leads to autoimmunity and persistent tissue damage, allowing for the restoration of homeostasis. They thus represent an efficacious and safe strategy for SLE.

1691 Novel CRISPR-Associated Gene Editing Systems Enable Efficient and Specific TRAC/TRBC Knockout Triggering Robust Expression and Sensitivity of a T Cell Receptor Specific for Mutant KRAS G12D

Nicholas Rouillard[1], Cheryl Black[2], James Parsons[2], Anthony Thomas[2], Allison Drain[1], Santosh Narayan[1], Nicole Danek[1], Nathaniel Swanson[1], Vince Nguyen[1], Joshua Francis[1], Xingyue He[1], Ankit Gupta[1], Gary Shapiro[1], Patrick Browne[3], Rebecca Lamothe[3], Gregory Cost[3], Ashley Thelen[4], Jessica Webb[4], Thomas Schmitt[4], Philip Greenberg[4], Loic Vincent[1]

[1]Affini-T Therapeutics, Watertown, MA,[2]Affini-T Therapeutics, Seattle, WA,[3]Metagenomi, Emeryville, CA,[4]Program in Immunology and Clinical Research Division, Fred Hutchinson Cancer Research Center, Seattle, WA

Adoptive T cell therapy (ACT) has demonstrated activity in solid tumors, but further optimization is needed to establish reproducibly effective treatments. T cells engineered with T cell receptors (TCRs) recognizing intracellular oncogenic drivers like mutant KRAS, the most frequently altered gene in human cancers, have the potential to induce durable responses in patients with solid tumors. TCRs are heterodimeric proteins consisting of a- and b-chains that can activate T cells following recognition of the desired target peptide presented by MHC. Competition between transgenic and endogenous TCRs for the available pool of CD3 proteins in T cells and the potential mispairing of transgenic and endogenous TCR chains can lead to decreased surface expression of the transgenic TCR, and thus diminished sensitivity. Here we employed programmable nucleases to genetically edit the constant regions of endogenous TCRs to eliminate endogenous TCR expression and mispairing with the transgenic TCR. We used a novel CRISPR-associated nuclease originally identified from environmental microbial samples and identified novel lead gRNAs that resulted in TCR knockout in >90% of human primary T cells. Since off-target activity is a potential safety risk, we characterized nuclease specificity using the 'gold standard' oligo capture assay followed by validation of any off-target activity using the Amplicon-sequencing assay. We demonstrated, with a sensitivity of detection approaching 0.1%, preclinical high specificity of editing, supporting safety of our gene edited TCR T cell therapy. To evaluate the functional impact of endogenous TCR

deletion, we edited primary T cells transduced with a lentivirus carrying CD8ab co-receptor and a TCR specific for the peptide derived from the KRAS G12D mutation presented in the context of HLA-A*11:01, one of the most common HLA alleles worldwide. TRAC/TRBC knockout improved expression of the transgenic TCR and improved the sensitivity of the engineered T cells, with TRAC/TRBC edited cells exhibiting enhanced *in vitro* cytotoxicity against tumor cells expressing the mutant KRAS G12D peptide. In summary, we describe the importance of genetic knockout of endogenous TRAC and TRBC for increasing the safety and functional potential of TCR-based cell therapy against solid tumors. The functional benefit and specificity of our genetic editing supports utility in clinical development of TCR-engineered T cell therapy for treating KRAS-mutant solid tumors.

1692 Focal Radiotherapy Improves the Efficacy of CAR T Cells Directed Against Prostate Cancer

Cari A. Young[1], John P. Murad[2], Lea Christian[2], Stephen J. Forman[2], Tanya B. Dorff[3], Saul J. Priceman[2]

[1]Irell and Manella Graduate School of Biological Sciences, City of Hope, Duarte, CA,[2]Department of Hematology and Hematopoietic Cell Transplantation, City of Hope, Duarte, CA,[3]Department of Medical Oncology & Therapeutics Research, City of Hope, Duarte, CA

Chimeric antigen receptor (CAR) T cell therapy is an adoptive cell immunotherapy that has demonstrated great clinical efficacy treating hematological malignancies. Unfortunately, persistent and durable responses against solid tumors are limited due to low infiltration, trafficking, and activity of CAR T cells within the immunosuppressive tumor microenvironment (TME). These challenges can potentially be overcome by combining CAR T cells with other therapies that remodel the TME, alleviate immunosuppression, improve T cell infiltration, and promote endogenous immune responses. As such, our group recently found that pre-conditioning with lymphodepleting agent, cyclophosphamide (Cy), modulates the TME to become less hostile and enhances the recruitment and activity of endogenous and CAR T cells targeting the human prostate stem cell antigen (hPSCA) against mouse prostate cancer. Similarly, focal radiation therapy (RT) is also known to have immunomodulatory and tumoricidal effects that can alter the TME of otherwise immunologically "cold" tumors; however, little is known about how the immunomodulatory effects of focal RT may promote CAR T cells in the treatment of solid tumors. Our experiments have shown that combining Cy pre-conditioning with focal RT and PSCA-CAR T cell treatments significantly improves therapeutic responses and survival in mice engrafted with a single mouse prostate tumor. Furthermore, we empirically determined the optimal dose and fractions of RT that induced the most beneficial changes within the TME, including greater immune cell infiltration, dendritic cell maturation, and MHC Class I antigen presentation. To this end, we found that distal, non-irradiated tumors exhibited greater sensitivity to systemic PSCA-CAR T cells treatment following single tumor site focal RT treatment combined with Cy pre-conditioning. Cured mice who were rechallenged with wild-type antigen-negative tumors also demonstrated the longest delay in tumor out-growth compared to other initially cured mice treated without RT, indicating that the RT, Cy, and PSCA-CAR T cell treatments induced the strongest protective immune response. Our studies show that our focal RT combination treatment strategies enhance the anti-tumor activity of CAR T cells and may contribute to a more robust systemic immune response against metastatic burden in prostate cancer.

1693 Dasatinib: A Src Kinase Inhibitor to Prevent Anti-AAV Antibody Response and Enable AAV Re-Administration in Mice

Rebecca Xicluna, Emily Seeger, Waiz David, Schwandt Timo, Hélène Haegel

Roche pRED Pharmaceutical Sciences, Basel, Switzerland

Introduction: Recombinant Adeno-associated virus (rAAV) is a promising vector for in vivo gene therapy due to its safety and efficacy and many rAAV-mediated gene therapy clinical trials are ongoing. Nevertheless the humoral response to the vector capsid remains a main challenge. Anti-AAV neutralizing antibodies completely prevent redosing and may be linked to some of the adverse events reported in clinical trials. For patients treated very early in life, readministration may be needed. It is therefore of high interest to investigate immunomodulatory strategies to prevent the humoral immune response against AAV vectors. We tested the effects of two different kinase inhibitors, dasatinib and acalabrutinib respectively targeting Src and BTK, on the antibody response to AAV capsid and efficacy of vector re-dosing in mice. **Methods:** Starting 2 hrs before the first rAAV dosing, 4 groups of 10 C57Bl6 mice were treated for one week only with dasatinib, acalabrutinib, dexamethasone or no treatment (control) respectively. Mice were immunized against AAV8 by intravenous injection of a rAAV8 coding for the human Secreted Alkaline Phosphatase (hSEAP) on day 0 and received a second intravenous injection of a rAAV8 encoding Factor IX on day 22. Both transgenes, hSEAP and hFactor IX concentrations were measured in the plasma over time until sacrifice on day 36. Anti-AAV IgM and IgG titers were also assessed over time, using ELISA assays. The effect of dasatinib was also investigated in vitro in human whole blood assays, to assess its effects on cytokine and chemokine release in response to rAAV. **Results and Conclusion:** Transient treatment with dasatinib led to a strong reduction in anti-AAV8 IgM and IgG antibodies and hence allowed transduction by a second rAAV8, leading to expression of the transgene product hFIX. Acalabrutinib treatment showed some but lower efficacy. Treatment with dexamethasone did not impact anti-AAV antibody formation. In some of the dasatinib- and acalabrutinib- treated mice, anti-AAV ADAs started to increase before the 2nd AAV8 injection suggesting that the treatment should be prolonged. AAV8 particles may persist in blood and tissues after the end of the immunosuppressive treatment. The immunosuppressive effects of the tested compounds were transient, as the treated mice had similar anti-AAV8 ADAs titers as untreated mice at day 36 showing that they had recovered immunocompetence. In the human whole blood assay system, dasatinib inhibited the AAV-dependent release of some cytokines in response to rAAV in vitro. Overall, transient treatment with the Src inhibitor dasatinib appears to be a promising strategy to prevent the humoral response to AAV8 and warrants further investigation in the context of AAV-mediated gene transfer.

1694 Patient-Derived iPSC-Neurons and Microglia for Modeling Friedreich's Ataxia Disease

Priyanka Mishra, Anusha Sivakumar, Avalon Johnson, Emily Hansen, Jacqueline Nguyen, Nicole Coufal, Stephanie Cherqui

University of California, San Diego, La Jolla, CA

Friedreich ataxia (FA) is a neurogenerative disorder caused by homozygous GAA expansion mutation in the first intron of frataxin (*FXN*) gene. FXN is a mitochondrial protein, and its deficiency leads to mitochondrial iron overload, defective energy production, and oxidative stress. We previously showed complete rescue of neurologic, complications of FRDA in YG8R mice with a single, systemic infusion of wild-type hematopoietic stem and progenitor cells (HSPC), and rescue was mediated by FXN transfer from engrafted HSPC-derived microglia to diseased neurons.. We next developed an autologous stem cell transplantation approach using CRISPR/Cas9-mediated excision of GAA repeats in FRDA patients' $CD34^+$ HSPCs that increased frataxin expression and improved mitochondrial functions. The aim of the current study is to understand FRDA neurodegeneration in the context of microglia and the complex interaction between HSPC-derived microglia and neurons in disease pathogenesis. To this end, we generated a unique cohort of four different FRDA patient-derived induced pluripotent stem cells (iPSCs) along with the CRISPR/Cas9-gene edited FRDA iPSCs, two familial carriers and two unrelated control lines. These iPSCs were then used for generating cortical neurons and microglia (iMG) and "mini-brains". FRDA-neurons displayed increased Caspase-3 expression and non-homogenous microtubule staining in neurites and cell body, characteristic of apoptosis, as opposed to edited-neurons and non-affected controls. FRDA-neurons also displayed increased mitochondrial fragmentation, partially degraded cristae structure, elevated superoxide production, and membrane potential loss, which were not seen in the edited neurons and controls. Similarly, FRDA-iMGs displayed activated, amoeboid morphology with compromised phagocytosis, and mitochondrial dysfunction while the edited-iMGs exhibit a phenotype comparable to controls. Utilising these two models, to understand the role of microglia in the neurodegeneration in FRDA, and its rescue by the gene corrected microglia.

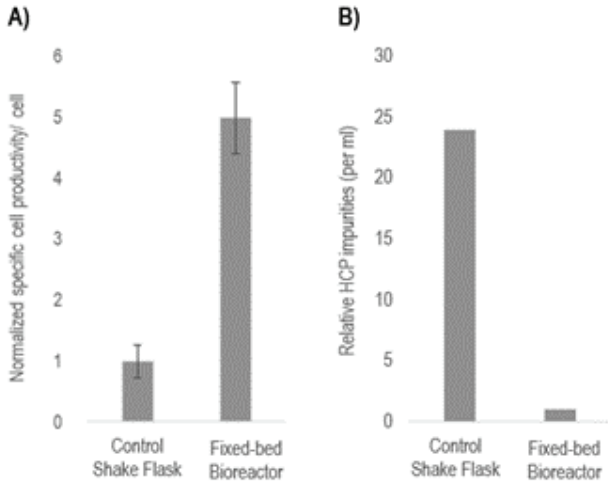
1695 Intensified AAV Manufacturing Using a Scalable, High-Cell Density Platform Supporting Increased Specific Productivities

Clémence De Schoutheete[1], Tania Pereira Chilima[2]

[1]Univercells Technologies, Nivelles, Belgium,[2]Univercells, SA, Gosselies, Belgium

Considerable advances have been made in the monoclonal antibody industry to increase volumetric productivities, in large part through upstream intensification and the application of continuous processing. This has enabled manufacturers to generate large quantities of product using suspension-based processes in stirred-tank bioreactors (STR). While these improvements can provide a blueprint for commercial-scale manufacturing in the viral vector field, gene therapy developers remain far behind in replicating such successes. The inherent complexity of manufacturing processes, the unique characteristics of viral products, and scalability challenges are key factors in this struggle. The latter is especially pronounced for adeno-associated virus (AAV) developers aiming to achieve large-scale production while maintaining critical process parameters and meeting quality attributes. Limitations of STR systems, wherein key parameters such as shear, mixing and gas exchange cannot be simultaneously and linearly scaled-up, significantly constrain the design space for developers and can impact cost effectiveness of manufacturing processes.In this session, the speaker will present an intensified AAV manufacturing platform based on structured fixed-bed technology and designed to address the above-mentioned issues for both adherent and suspension platforms. By enabling transfection at >25x10^6 cells/mL without aggregation in a drastically reduced working volume, the upstream intensification of AAV manufacturing is unlocked, opening the way to cost-effective, large-scale production. The speaker will illustrate how a low shear, homogenous bioreactor environment leads to a 5-fold increase in specific productivity and present data supporting maintained performance across scales. The benefits of cell immobilization in the bioreactor will be described, circumventing the need for additional cell retention devices while achieving a >20-fold reduction in contaminating host cell protein. Finally, the speaker will present an integrated platform solution combining upstream and midstream operations, enabling combination of intensification with continuous processing for an optimized, low-footprint manufacturing workflow

Figure 1. Increased productivity and reduced impurity profile in a structured fixed-bed bioreactor. B) Normalized host cell protein (HCP) concentration per mL



1696 Stem Cells from Human Exfoliated Deciduous Teeth (SHED) Obtained by a Serum-Free Method Induced Significant Angiogenesis and Restored Blood Flow in a Rat Model of Critical Limb Ischemia

Noritaka Fukuda, Mei Natori, Hiromi Takaki-Ariki, Yasuyuki Mitani

Kidswell Bio corporation, Tokyo, Japan

Stem cells from human exfoliated deciduous teeth (SHED) are mesenchymal stem cells (MSCs) isolated from the dental pulp tissue. We developed a serum-free isolation/culture method and obtained the SHED with high proliferative capacity (KWB-SHED). KWB-SHED express surface MSC markers (positive for CD90, CD105 and CD73, negative for CD45, CD19, CD14, CD34 and HLA-DR), and have abilities of colony formation and trilineage differentiation same as conventional SHED cultured using fetal bovine serum (FBS-SHED). Microarray analysis revealed KWB-SHED highly expressed the genes associated with angiogenesis compared to FBS-SHED. Indeed, ELISA and multiplex analysis showed KWB-SHED secreted higher amount of angiogenic factors such as SCF, BDNF and ANGPTL4 than FBS-SHED on multiple donors. Furthermore, the conditioned media with KWB-SHED highly promoted proliferation of and tubule formation with human vascular endothelial cells (HUVEC) while the conditioned media with FBS-SHED had no effect. Next, we tested *in vivo* angiogenic activity of KWB-SHED using a rat model of critical limb ischemia (CLI). Intra-muscular administration of KWB-SHED to the ischemic limb showed a robust improvement of blood flow at the site of ischemia and avoidance of limb loss (Fig.1). Immunohistochemical analysis revealed a significant increase of blood vessels by SHED injection. Thus, KWB-SHED have high angiogenic capacity, suggesting potential clinical application for ischemic diseases requiring angiogenesis such as CLI.

1697 TALEN-Mediated Gene Editing of *LPA* Results in Gene Disruption and Plasma Lipoprotein(a) Reduction in Transgenic Mice

Daniel A. Garcia

Arcturus Therapeutics, San Diego, CA

Lipoprotein(a), or Lp(a), is an independent and causal genetic risk factor for cardiovascular disease. Individuals with high Lp(a) levels in circulation are up to 8 times more likely to suffer a life-altering cardiovascular event and are refractory to standard lipid-lowering agents. Lp(a) is a lipoprotein complex that contains apoB100 covalently bound to apo(a), the protein encoded by the *LPA* gene in humans. Apo(a) expression is restricted to the liver and Lp(a) levels in the circulation are genetically determined due to a repetitive exon that is polymorphic in human populations. Interestingly, natural homozygous loss of LPA in humans has not been associated with adverse phenotypes. These observations together suggest that LPA is an ideal candidate for a genome editing therapy geared towards reducing Lp(a) levels and resolving an unmet medical need. We designed TALEN®s, Transcription Activator-Like Effector Nucleases, that specifically target the human *LPA* gene and, after sequence optimization, the TALEN mRNAs were transfected into human primary hepatocyte cells to confirm their protein expression and gene editing activity. The *LPA*-targeted TALEN mRNAs were then formulated with Arcturus's proprietary LUNAR® lipid nanoparticle (LNP) and injected intravenously in a transgenic mouse model harboring a human LPA transgene. The LUNAR-LPA TALEN formulation targeted the liver and was well-tolerated. A single dose resulted in substantial reduction in plasma Lp(a) levels, which was sustained up to several weeks post-administration. Next-Gen amplicon sequencing and long-read HiFi sequencing confirmed the presence of gene-inactivating insertions and deletions at the *LPA* locus. *LPA* transcripts were reduced in liver tissue as evidenced by RNAseq and RT-qPCR, further confirming gene disruption. We also found that plasma levels of plasminogen, which is highly homologous to apo(a), were not affected suggesting minimal off-target gene editing. Overall, this study serves as a proof-of-concept for using TALEN-mediated gene editing to disrupt *LPA in vivo*, paving the way for the development of a long-term gene editing therapy for patients with high Lp(a).

1698 Fitness Maturation of Engineered AAV Capsids STAC-102 and STAC-103 Enhances Central Nervous System Transduction after CSF Administration in Cynomolgus Macaques

David S. Ojala, Lori Andrews, Ankitha Nanjaraj, Matthew R. Tiffany, Nathan Palmer, Yuri Bendaña, Russell Darst, Stephen Wist, Alicia Goodwin, Kenneth Kennard, Sarah Mueller, Amy Pooler

Sangamo Therapeutics, Inc., Richmond, CA

The clinical translation of genomic medicines to treat disorders of the central nervous system (CNS) has been hampered by inefficient gene delivery. AAV administration into the cerebrospinal fluid (CSF) enables access to the CNS with relatively low doses and limited exposure to pre-existing anti-AAV antibodies. However, the level of CNS delivery mediated by conventional AAV serotypes is lower than is needed to affect many neurological diseases. We previously applied the functional selection platform SIFTER (Selecting In vivo for Transduction and Expression of RNA) to identify capsids with improved CNS transduction after CSF administration. The engineered capsids STAC-102 and STAC-103 exhibited up to a 100-fold enrichment in both vector genome biodistribution and mRNA expression compared to AAV9 across many CNS regions. Here we applied fitness maturation strategies to further enhance the performance of capsids STAC-102 and STAC-103. Focused fitness maturation libraries were constructed to

evaluate how combinations of capsid mutations influence potency and manufacturability. Transduction efficiency was assessed *in vivo* after intra cisterna magna delivery in cynomolgus macaques and *in vitro* in human iPSC-derived neurons and primary mouse cortical neurons. Capsid manufacturing yield was assessed in suspension HEK293 cells. Each capsid in the library was synthesized with three unique barcodes and each barcode was coupled to multiple unique molecular identifiers. Variants of STAC-102 and STAC-103 were ranked based on multiple factors including fold enrichment in mRNA expression, DNA vector genome delivery, and unique molecular identifier counts. Results from these experiments showed that minor changes to the inserted peptide or flanking capsid sequences can significantly impact both capsid potency and manufacturing yield. Moreover, we found a subset of mutations that were globally beneficial in the tested assays, while others showed substantially divergent outcomes. In cynomolgus macaques we identified capsid variants with improved CNS delivery relative to the first generation STAC-102 and STAC-103 capsids. We are evaluating these new capsid derivatives as potential candidates for therapeutic approaches to treat neurological disorders.
