Hemophilia A (HA) is a monogenic bleeding disorder caused by low circulating coagulation factor VIII (FVIII) which results in spontaneous hemorrhages. In humans, the standard of care of prophylactic FVIII infusions has recently been challenged by non-factor therapies; however, both carry the burden of routine administration. Liver-directed adeno-associated virus (AAV) gene therapy is a potential one-time treatment that can significantly ameliorate the disease phenotype. However, questions remain about possible AAV oncogenic risk and longevity of transgene expression after gene transfer. HA dogs housed in research colonies have been used as preclinical models in therapeutic studies due to the similarities of their disease phenotype and predictability of dose response. Studies in privately owned HA dogs, in addition to providing quality of life data, may provide a better real-world estimate of AAV gene therapy safety and efficacy in clinical practice. Here, we present long term data on AAV gene therapy in privately owned HA dogs. 11 privately owned dogs with severe HA were treated with AAV8 vectors to express canine (c) FVIII. Three vector constructs were employed, and doses ranged from $5.4x10^{12}$ to $2.5x10^{13}$ vg/kg. In all recipients with available data (n = 10), cFVIII activity increased to >1% normal, with a median cFVIII activity of 3.2% (range 1.1 - 13.8%) after 4.1 years (range 2.6 - 8.9 years). These FVIII transgene levels resulted in a 93% reduction in the annualized bleeding rate. No new anti-cFVIII antibodies developed after gene therapy. However, a pre-existing anti-cFVIII antibody resolved in one recipient (PC3) after gene therapy. 3 dogs have died during follow up; 2 dogs (PC1 and PC3) with cFVIII <3% died at 8.8- and 2-years post treatment due to bleeding events. The last dog, PC9, was euthanized 3 years after gene therapy due to pervasive multicentric lymphoma. PC9's B-cell lymphoma showed high levels of cancer infiltration in the spleen and lymph nodes. Samples of PC9's liver, spleen, and lymph nodes were analyzed for presence of the human alpha1-antitrypsin promoter present in the AAV vector. Liver samples were found to have a vector copy number (VCN) of .05, splenic samples had a VCN of .02, and lymph node samples had a VCN of .0006. These VCNs are consistent with the normal biodistribution of AAV8 in a dog and well below the expected VCN if AAV integration had driven oncogenesis. Further AAV integration analysis found no evidence of a substantially expanded clone harboring vector integrations. In conclusion, AAV-cFVIII gene therapy is effective at reducing bleeding events in privately owned dogs. AAV gene therapy eradicated

a pre-existing anti-cFVIII immune response in one dog. The only serious adverse event was the development of cancer in one dog, which was rigorously determined to be unrelated to the AAV gene therapy. Terminal bleeding events occurred in dogs with moderate cFVIII activity, highlighting the need for levels >5%. These results support the safety and efficacy of AAV gene therapy for HA.

630 Alpha Globin Lentiviral Vectors for Hematopoietic Stem Cell Gene Therapy of Alpha-Thalassemia

Eva E. R. Segura Gensler[1], Kevin Tam[1], Beatriz Campo[1], Tippi C. MacKenzie[2], Georgia Gregori[3], Roger P. Hollis[1], Donald B. Kohn[4]

[1]UCLA, Los Angeles, CA,[2]University of California San Francisco, San Francisco, CA,[3]UCSF, San Francisco, CA,[4]Unversity of California, Los Angeles, Los Angeles, CA

α-thalassemia is an inherited blood disorder caused by mutations in α-globin genes (HBA1 and HBA2) resulting in the reduction of α-globin chains, the subunit, along with β-globin chain, constituting adult hemoglobin ($\alpha_2\beta_2$). Severe α-thalassemia arises with α-globin expression levels of <30%, and α/β-globin ratio of <0.3, caused by defects in or absence of three or all four α-globin genes. Treatment for survival entails lifelong, biweekly blood transfusions with daily iron chelation therapy. While these therapies enable patients to live into mid- to late-adulthood, they continue to engender serious clinical manifestations. To address this clinical need, our laboratory has developed a stem cell gene therapy in which functional copies of α-globin gene integrate into the genome of patient's hematopoietic and progenitor stem cells (HSPCs) by lentiviral vectors (LVs) to normalize the globin chain imbalance and restore hemoglobin function. The design of the α-globin LVs (AGLVs) is based on *GLOBE* β-globin LV utilized in a clinical trial for β-thalassemia, which has achieved transfusion independence in patients with transfusion-dependent β-thalassemia major. To target excess infective erythropoiesis and hemoglobin restoration, we have constructed a series of short proviral length AGLVs for optimized titer production, HSPC infectivity, and gene expression. We constructed twelve AGLVs varying in gene and regulatory element compositions. Each AGLV was assessed for its raw titer yield, gene transfer efficiency, α-globin mRNA expression, and hemoglobin production in an α-globin knockout (KO) HUDEP human erythroid cell line. Successfully, **all AGLVs confer high raw titers ~ 1e7 TU/mL and express α-globin chain yielding adult hemoglobin**. We identified two optimal AGLVs for further characterization in human primary HSPCs: *Alpha2* for yielding highest raw titer and gene transfer efficiency and *LCR-Globe* for producing highest α-globin mRNA expression. Both *Alpha2* and *LCR-Globe* LVs harbor the HBA2 gene regulated by the β-globin promoter, but they differ by the length of their β-Locus Control Region (LCR) enhancer. To assess candidate AGLVs in healthy human HSPCs, AGLVs were tagged at the transcription level to enable identification and quantification of vector-derived α-globin mRNA proceeding HSPCs transduction and erythroid differentiation. Although *Alpha2* demonstrated optimum $CD34^+$ infectivity and gene transfer, ***LCR-Globe* expressed up to ~30% α-globin mRNA per total β-globin mRNA per vector copy number** (VCN), which is in the range of wildtype α-globin levels produced by one endogenous α-globin allele (~25% α-globin mRNA per total β-globin mRNA). We further examined *LCR-Globe* $CD34^+$ infectivity, erythropoiesis, and hemoglobin correction in α-thalassemia major patient HSPCs harboring lethal homozygous deletion of both HBA1 and HBA2. These studies demonstrated *a high CD34+ infectivity and gene transfer, without utilization of transduction enhancers, and obtained a correction of α/β-globin mRNA ratio of ~0.4 while retaining a low VCN of ~2.* Such results in patient cells are encouraging for disease amelioration in severe cases of α-thalassemia. Additional studies are underway, examining homologous candidate murine AGLVs in an α-KO murine erythroid cell line. They will then be evaluated in a α-thalassemia murine model for disease correction *in vivo.* Completion of these studies will enable the identification of a therapeutic AGLV candidate for gene therapy for α-thalassemia.

631 UM171 Promotes Gene Transfer, Reduces Apoptosis and DNA Damage and Increases Engraftment of Gene Modified Peripheral Blood Hematopoietic Stem Cells from Sickle Cells Disease Patients

Boya Liu[1], Denise Klatt[2], Christian Brendel[3], John Manis[1], Jalila Chagraoui[4], Guy Sauvageau[4], David A. Williams[1]

[1]Boston Children's Hospital, Boston, MA,[2]Dana Farber Cancer Institute, Brookline, MA,[3]Boston Children's Hospital/Dana-Farber Cancer Institute, Boston, MA,[4]Institute for Research in Immunology and Cancer, Montreal, QC, Canada

Sickle cell disease (SCD) is one of the most common genetic blood diseases. Lentivirus transduced autologous hematopoietic stem cell transplantation is an effective therapeutic strategy for SCD. Enhanced gene transfer efficiencies, reduced manufacturing stress and higher yields of engrafting transduced hematopoietic stem cells (HSCs) are ultimate goals for improving clinical protocols that use autologous gene therapies. Here, we aimed to improve the transduction efficiency, stem cell fitness and reconstitution of SCD CD34+ cells transduced with a lentiviral vector (LV) containing BCL11A shmiR currently in clinical trials (Esrick et al. NEJM, 2021), to minimize potential damage during ex vivo culture and reduce the risk of accumulating genome damage. UM171, an HSC self-renewal pyrimidoindole derivative agonist, has been shown to expand HSCs and enhance multilineage blood cell reconstitution in mice. We tested the potential of UM171 to expand CD34+ stem cells derived from SCD peripheral blood (PB) HSCs and examined its effects on transduction, stem cell immunophenotype, apoptosis, cell cycle, DNA damage and engraftment. Culture of SCD CD34+ HSC in HSC expansion conditions with UM171 increased the proportion of CD34+CD38- cells and CD34+CD38-CD45RA-CD90+ long term HSCs (LT-HSCs), and the absolute number of CD34+CD38- cells and CD34+CD38-CD45RA-CD90+ LT-HSCs were increased 2- and 4-fold, respectively. Treatment with UM171 in vitro also significantly enhanced the transduction efficiency of BCL11A shmiR containing lentiviral vector (LV-BCL11A) in SCD CD34+ cells from 0.7 VCN to 1.0 VCN ($N = 5$, $P < 0.001$), and significantly decreased apoptosis of stem cells, and reduced DNA damage determined by γH2AX+ assays (see Table). We assessed the engraftment capability of SCD CD34+ transduced in the presence or absence of UM171 in NBSGW mice. UM171 increased the human CD45 engraftment of mice

measured in PB at 8 weeks post-transplantation (N = 3, P = 0.05) and enhanced the engraftment of lentivirus transduced in SCD CD34+-derived CD45+ cells (N = 3, P <0.05) (see Table). To assess the effect of UM171 more rigorously on functionally defined HSCs, we performed a competitive transplantation assay using CD34+ cells transduced in the presence vs absence of UM171. Analysis of PB obtained from the mice at 8 weeks post-transplantation showed that cells transduced in the presence of UM171 consistently outcompeted those transduced under control conditions, 57.5% compared with 42.5% (N = 9, P < 0.001). In summary, a short-time exposure of SCD CD34+ PB cells to UM171 enhances the LV-mediated transduction efficiency of HSCs derived from SCD patients, reduces DNA damage and apoptosis during ex vivo manipulation and enhances engraftment of gene modified cells in xenograft models. Implementing these findings in clinical gene therapy protocols may improve the efficacy and sustainability of gene therapy and generate new opportunities in the field of gene editing.

Functional phenotype of SCD stem cells transduce with LV-BCL11A in presence of UM171				
	Apoptosis of stem cells (%)	DNA damage (%)	Transduction efficacy (%)	Engraftment (%)
In absence of UM171	22.5 ± 6.7	10.6 ± 1.1	13.6 ± 2.6	6.3 ± 1.3
In presence of UM171	14.3 ± 2.4	6.6 ± 1.5	19.9 ± 2.9	9.3 ± 1.4
P value	< 0.001	< 0.001	<0.05	0.0502

632 Treatment of Canine Hemophilia A via Intraosseous Delivery of a Platelet-Specific Factor VIII-Lentiviral Vector

Cameron W. Rementer[1], Chong Li[2], Timothy C. Nichols[3], Xiaohe Cai[1], Julia H. Joo[4], Xuefeng Wang[5], Elizabeth Merricks[3], Hans D. Ochs[1], David J. Rawlings[6], Carol H. Miao[7]

[1]Immunity and Immunotherapies, Seattle Children's Research Institute - Seattle, Washington, Seattle, WA,[2]Seattle Childrens Hospital, Seattle, WA,[3]UNC at Chapel Hill Francis Owen Blood Rsch. Lab., Chapel Hill, NC,[4]Seattle Children's Research Institute, Seattle, WA,[5]Seattle Children's Research Institute, Shoreline, WA,[6]University of Washington, Seattle, WA,[7]Seattle Children's Research Institute, Seattle, WA

Hemophilia A (HemA) is a genetic disease resulting from a factor VIII (FVIII) deficiency. Traditional protein infusion to treat HemA is costly and requires repeated dosing. We demonstrated previously that intraosseous (IO) gene therapy via delivery of lentiviral vectors (LVs) into bone marrow targeting FVIII expression in platelets successfully treated HemA mice, including mice that had developed FVIII inhibitors. To facilitate clinical translation, we investigated the treatment of HemA dogs using this approach. A lentiviral vector incorporating a platelet-specific promoter Gp1bα and canine FVIII gene was injected into the tibia/iliac bones of 5 HemA dogs (4 in Cohort #1, 1 in Cohort #2). Prior to injection, the dogs were treated with an immune modulation regimen to minimize the immune response. Following the procedure, blood samples were taken at various timepoints. All dogs recovered well from the procedure and had blood chemistry values within normal ranges. Expression of cFVIII was examined in platelets and plasma isolated from LV-treated dogs by ELISA and aPTT assays. Canine FVIII can be detected in platelets with the highest expression at 5-10 mU/10^8 platelets around 1-2 months post-procedure and expression persisted for the experimental duration in all treated dogs. There was no canine FVIII expression detected in treated dog plasma. The improvement of blood coagulation was evaluated by whole blood clotting time (WBCT) and thromboelastography. WBCT was shortened in multiple time points shortly after IO gene therapy, indicating improved hemostasis. Furthermore, the IO gene therapy was well tolerated and did not produce any toxicity as evaluated by CBC and blood chemistry analysis**.** Encouragingly, the dogs experienced fewer bleeding events per year after gene therapy treatment compared with the baseline prior treatment, indicating partial correction of HemA phenotype. For the first dog in Cohort #2, we incorporated several improvements over our previous protocol. Specifically, we performed injections in both the tibia and the iliac bone. Additionally, perioperative hemostasis was performed using bypassing agents to avoid inhibitor formation. At 3 weeks, canine FVIII can already be detected in platelets by ELISA with stable levels over the 2 months of follow-up. In conclusion, we have established an IO-LV gene therapy protocol to treat HemA dogs successfully with persistent effects of treatment over 2-4 years. Our study demonstrated a potential strategy for safe and effective application of gene therapy *in vivo* for treating HemA patients.

633 Destruction of T Cell Synapse Formation is a Novel Strategy for Hypoimmunity

Jiabiao Hu, Yixuan Zhou, Xiaomeng Bian, Lina Zhou, George Church, Luhan Yang

Qihan Biotech, Hangzhou, China

Allogeneic immune cells derived from engineered human induced pluripotent stem cells are becoming promising cell therapies for cancer. However, host-versus-graft rejection limits their durability in patients, particularly when the treatment involves multiple doses. The rejection mainly comes from host T cells. Knocking out of MHC-I/II has been proven to be effective for avoiding T cell attack while making the edited cells susceptible to host NK killing, due to the miss-self signal. Although numerous efforts have been applied to further engineer MHC-I/II KO with different NK inhibitory ligands, the high heterogeneity of NK cells renders it challenging to suppress all patient NK cells by expressing a few NK inhibitory factors. Alternatively, inhibiting host T cells without knocking out MHC-I could be a potential strategy for generating hypoimmunogenic cell products.In this study, we tested this alternative strategy by knocking out T cell second signaling molecules from T cell synapse for escaping host T cell immunity while preserving MHC-I for preventing host NK killing. We screened a panel of T cell second signaling molecules and found that knocking out some of the molecules significantly reduced the stimulation to T cells. Importantly, the allogeneic cells with a simultaneous knockout of molecules M1 and M2 would not elicit T cell immunity, which was comparable to MHC-I KO. We then applied the edits on GMP-grade human iPSCs and demonstrated that M1/M2 double knockout did not impact NK differentiation and had robust resistance towards human T cells and NK cells *in vitro.* Taken together, we identified that destruction of T cell synapse formation could render iPSCs-derived NK cells hypoimmunogenic in vitro. We anticipate that this could be a simple and useful asset to greatly enhance cell therapy efficacy.

634 CAR-Treg Cells Differentiated *In Vivo* by Transduced Hematopoietic Stem Cells: A New Approach to Treatment of Autoimmune Disorders

Greg Crawford, Lily Du, Ana Luiz, Valentina Pennucci, Tomasz Zabinski, Paul Heal, Piv Sagoo, Bobby Gaspar, Fulvio Mavilio, Chiara Recchi

Orchard Therapeutics, London, United Kingdom

Autoimmune diseases such as multiple sclerosis (MS) are commonly treated with non-specific anti-inflammatory drugs. Autologous hematopoietic stem cell (HSC) transplantation shows efficacy in some forms of MS by providing an "immune reset" function, even though it does not specifically target autoimmune-mediated neurodegeneration. Several studies showed that adoptive transfer of regulatory T cells (Tregs) expressing chimeric antigen receptors (CAR) directly addresses autoimmunity in murine models of MS. Though promising, this approach faces limitations regarding Treg stability *in vivo* and long-term efficacy. We are developing a new approach to treat autoimmune conditions, by enabling Treg therapy through transplantation of autologous HSCs genetically modified with a lentiviral vector to express an antigen-specific CAR under Treg-restricted transcriptional control. Genetically modified HSCs have the potential to generate stable, long-lived antigen-specific CAR-Tregs *in vivo* (Fig. 1).

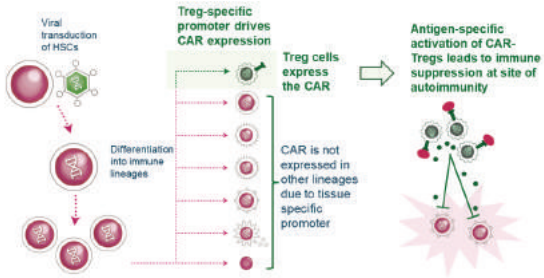

Figure 1. HSC-derived CAR-Tregs. An antigen-specific CAR is selectively expressed in differentiated Treg cells due to Treg-restricted transcriptional regulation. CAR-Tregs can be specifically activated by (auto)antigens, leading to local suppression of autoreactive responses.

Candidate transcriptional regulatory elements derived from the human FOXP3 gene were characterized in different combinations for activity and specificity in a lentiviral vector construct both *in vitro,* in primary murine and human T cells, and *in vivo,* upon transplantation of transduced HSCs into lethally conditioned mice. FOXP3-derived synthetic promoters are preferentially activated in Tregs in both contexts. In parallel, CARs were designed to induce Treg functions upon engagement with specific target antigens, leading to secretion of the immunosuppressive cytokine IL-10 from transduced murine and human Tregs upon antigen stimulation *in vitro*. To demonstrate the concept in vivo, murine lineage negative hematopoietic stem/progenitor cells (*Lin*$^-$ HSPCs) were transduced with lentiviral vectors to express CAR under the control of the FOXP3-derived synthetic promoter and transplanted into recipient mice. The CAR was efficiently expressed in Tregs 3 months post-transplant (Fig. 2A), with no impact on normal Treg development, phenotype or function. *Ex vivo* ligand-specific activation of CAR-Tregs led to enhanced Treg function with increased expression of CD25 (Fig. 2B) and IL-10 secretion (Fig. 2C).

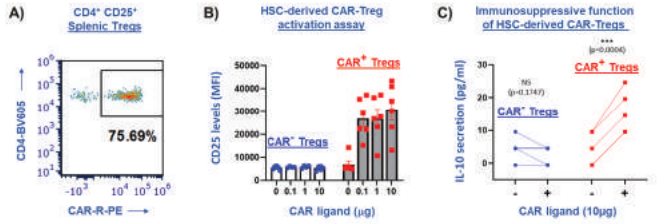

Figure 2. HSC-derived CAR-Tregs express a functional CAR *in vivo*. Mice were transplanted with *Lin*$^-$ HSPCs transduced with LVs designed to express an antigen-specific CAR under the control of a Treg-restricted promoter. Splenic Tregs successfully express the CAR **(A)** and respond to ligand-specific stimulation by increasing CD25 levels **(B)** and IL-10 secretion **(C)**.

These data represent a first preclinical proof of concept for the generation of functional CAR-Tregs *in vivo* from genetically engineered HSCs, and a first step towards the development of potential lifelong treatments for chronic autoimmune disorders.

635 Regulated Expression of GATA1 as a Gene Therapy Cure for Diamond-Blackfan Anemia

Richard A. Voit[1,2,3], Xiaotian Liao[1,3], Blake Cohen[1,3], Myriam A. Armant[4], Elena Kamal[1,3], Mei-Mei Huang[1], Christine Duncan[2], Akiko Shimamura[1], David A. Williams[1], Vijay G. Sankaran[1,2,3]

[1]Division of Hematology, Boston Children's Hospital, Boston, MA,[2]Dana Farber/Children's Hospital Cancer Center, Boston, MA,[3]Broad Institute, Cambridge, MA,[4]Boston Children's Hospital, Boston, MA

Diamond-Blackfan anemia (DBA) is a bone marrow failure disorder characterized by severe anemia due to impaired red blood cell production, and has limited treatment options. More effective, safer, and permanent cures for DBA are desperately needed, but few drugs are in active development. DBA is genetically heterogenous, caused by haploinsufficiency in 1 of at least 26 different ribosomal protein (RP) genes that alters the translation of select transcripts, most notably the erythroid master regulator GATA1. Constitutive expression of GATA1 in hematopoietic stem cells (HSCs) from patients with DBA rescues the erythroid differentiation defects *in vitro* but impairs long-term (LT-) HSC function. Gene therapy is an attractive strategy to achieve a cure for DBA, but a traditional gene therapy approach that overexpresses a functional copy of a mutated gene requires the development and validation of dozens of gene therapy vectors, each with a copy of one of the mutated DBA genes. Here, we report a unified gene therapy strategy, using developmentally regulated expression of GATA1 to be curative in most, if not all, patients with DBA, regardless of the underlying disease-causing mutation. We sought to design a GATA1 gene therapy vector that incorporates into the genome of undifferentiated LT-HSCs but only drives robust GATA1 expression in committed erythroid progenitors. To achieve this, we identified chromatin regions upstream of *GATA1* that are accessible only in differentiating erythroid cells, but not in HSCs. Using those selectively accessible regions concatenated together, we constructed a human GATA1 enhancer (hG1E) element and used it to drive GATA1 and/or GFP expression from a lentiviral backbone in HSCs collected from healthy human donors. We observed very low transgene expression in bulk HSCs and essentially no expression

in the subpopulation of LT-HSCs with no impairment in stem cell function *in vivo*. However, more than 80% of committed erythroid cells demonstrated high levels of transgene expression, confirming the fidelity of lineage-restricted expression from the hG1E-GATA1 vector. To examine whether lineage-restricted GATA1 expression confers a functional correction of the erythroid maturation block in DBA, we used CRISPR editing to recapitulate *RPS19* haploinsufficiency in human HSPCs. In *RPS19* edited samples treated with a control GFP virus, we observed a progressive selection against *RPS19* edited cells as they underwent erythroid differentiation. In contrast, *RPS19*-edited and hG1E-GATA1 treated samples had a more than 10-fold higher preservation of *RPS19* edits in the bulk population and in erythroid colonies derived from single progenitor clones, indicating that regulated GATA1 expression can overcome *RPS19* haploinsufficiency. To validate these results, we treated primary bone marrow samples from 10 DBA patients with varied genotypes, representing almost 75% of all DBA patients with a defined genetic cause. Control treated cells showed impaired erythroid differentiation with skewing down the myeloid and megakaryocyte lineages. In contrast, regulated GATA1 expression from the hG1E-GATA1 vector in DBA patient cells led to a restoration of erythroid differentiation with significantly increased erythroid output. Additional preclinical safety and *in vivo* efficacy studies are ongoing. Collectively, our preclinical data demonstrate that lineage-restricted expression of GATA1 is sufficient to rescue the impaired erythroid differentiation in DBA regardless of the underlying genetic lesion. These results will set the stage for the first in-human gene therapy trial for DBA.

636 Development of KYV-101, a Novel CD19 CAR-T Cell Therapy for the Treatment of B Cell-Driven Autoimmune Diseases

Charles Kaplan, Soo Park, Erin O'Brien, Ames Register, Catherine Dong, Daniel Anaya, Ho-Young Lee, Dominic C. Borie, James Chung, Tom Van Blarcom

Kyverna Therapeutics, Emeryville, CA

Background: A significant unmet medical need remains in the treatment of relapsed and/or refractory B cell-driven autoimmune diseases. The presence of autoantibodies is a hallmark of such diseases and implicates dysregulated B cell function in their pathogenesis. The central role of B cells in these diseases is also supported by the presence of increased numbers of B cells in diseased tissues and the efficacious responses reported with biological therapies that target B cells. KYV-101 is an autologous CD19 chimeric antigen receptor (CAR)-T cell therapy that depletes pathogenic B cells. Importantly, the CD19 CAR utilized in KYV-101 was previously tested in B-cell lymphoma patients and demonstrated efficacy with an improved safety profile (1). Since CD19 CAR-T cells target and lyse B cells in both circulation and tissues, a more complete depletion of autoreactive B cells is expected with KYV-101 than biological therapies, resulting in better disease control and clinical remission than the current immunotherapies. **Methods:** Autologous $CD4^+$ and $CD8^+$ T cells were enriched from healthy donors (HD) and systemic lupus erythematosus (SLE) patients. KYV-101 CAR T cells were generated by transducing T cells with a lentiviral vector encoding a CAR comprised of a fully human single-chain variable fragment (scFv) CD19-targeting domain, a CD8a hinge and transmembrane domain, a CD28 cytoplasmic costimulatory domain, and a CD3z cytoplasmic domain. The binding affinity and specificity of the anti-CD19 scFv for recombinant human CD19 protein and $CD19^+$ cells were evaluated in vitro in a set of in BioLayer Interferometry, flow cytometry and cell-based protein microarray screening studies. KYV-101 CAR-mediated and CD19-dependent activity was also monitored in vitro and in vivo in a set of cytotoxicity, cytokine release, proliferation, and tumor growth studies, in response to either a $CD19^+$ target cell line, autologous, patient-derived primary $CD19^+$ B cells, or a $CD19^-$ target cell line. **Results:** The anti-CD19 scFv used in KYV-101 bound with high affinity to both recombinant human CD19 protein and $CD19^+$ NALM6 cells. Moreover, the anti-CD19 scFv was specific for CD19 as no other specific interactions were observed in the cell-based protein microarray screen. KYV-101 demonstrated CAR-mediated and CD19-dependent activity in vitro. KYV-101 generated from HDs or SLE patients induced greater and dose-dependent cytotoxicity of both the human $CD19^+$ cell line (NALM6) and autologous, patient-derived primary B cells than their respective untransduced control T cells. Moreover, an effector cell dose-dependent increase in the production of cytokines such as IFNγ was also observed following co-culture. In contrast, no differences in cytotoxicity nor cytokine production were observed for KYV-101 or untransduced control T cells co-cultured with $CD19^-$ K562. Furthermore, KYV-101 generated from HDs or SLE patients showed enhanced proliferation when co-cultured with the $CD19^+$ NALM6 cells and autologous, patient derived primary B cells compared to the untransduced control T cells co-cultured with either $CD19^+$ or $CD19^-$ cells. Importantly, KYV-101 also demonstrated CAR-mediated mechanism of action in vivo as transferring KYV-101 into NSG mice inoculated subcutaneously with $CD19^+$ NALM6 tumor cells resulted in complete tumor ablation at doses of at least $3x10^6$ CAR^+ cells/mouse. **Conclusion:** KYV-101 generated from HDs and autoimmune disease patient lymphocytes demonstrates high affinity and specificity to human CD19 as well as CAR-mediated and CD19-dependent activity in vitro and in vivo against $CD19^+$ cell lines and/or autologous, patient-derived primary B cells. KYV-101 thus represents a novel therapeutic option for the depletion of pathogenic B cells in autoimmune patients. **References:** [1] Brudno JN, et al., Nat Med, 2020, 26(2):270-280

637 High-Throughput Screening of Polymers for *In Vivo* Hematopoietic Stem Cell Base Editing in a Novel Fanconi Anemia Murine Model

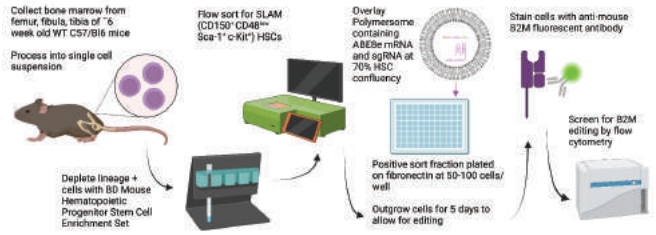
Ella J. Eaton[1], Christopher J. Sipe[1], Mckenna G. Hanson[2], Michael C. Leyden[2], Matthew J. Johnson[3], Theresa M. Reineke[2], Beau R. Webber[3], Branden S. Moriarity[3]

[1]Genetics, Cell Biology, & Development, University of Minnesota, Minneapolis, MN,[2]Chemistry, University of Minnesota, Minneapolis, MN,[3]Pediatric Hematology & Oncology, University of Minnesota, Minneapolis, MN

Allogeneic hematopoietic stem cell transplant (HSCT) is the current standard of care for bone marrow failure (BMF) associated with Fanconi anemia (FA). FA patients face unique challenges including difficulty sourcing matched donors, increased sensitivity to HSCT pre-conditioning regimens, and high risk of malignancy. The Spanish

founder mutation (1:64 carrier frequency) of FA arises from a single C→T nucleotide substitution in exon 4 of the *FANCA* gene and forms a premature stop codon that results in a truncated, non-functional FANCA protein. Restoration of the *FANCA* coding sequence to a functional variant in hematopoietic stem and progenitor cells (HSPCs) can reverse the effects of BMF. Recently published work by our group and that of Siegner et al. demonstrated that adenine base editor (ABE) can correct the Spanish founder mutation and restore protein function *in vitro*, prompting us to pursue novel approaches for *in vivo* correction. To facilitate these efforts, we generated a novel murine model in which exon 4 of the murine *Fanca* locus was replaced with human wild-type or mutant *FANCA* sequence, enabling the utilization of our validated human gene editing reagents in a clinically relevant animal model. Numerous methods for targeted *in vivo* delivery of genome editing reagents are under investigation, however, polymer-based delivery has the advantage of scalability and flexible modular design. We are performing high-throughput screening of polymer complexes for delivery to HSPCs, as shown in Figure 1. Initial screens will be carried out on primary C57BL/6 murine HSPCs *in vitro* by delivering ABE8e mRNA and sgRNA targeting β2-microglobulin (*B2m*), with functional editing of target HSPCs determined by flow cytometric quantitation of surface B2m expression. High-performing polymers will be combined with ABE8e mRNA and therapeutic sgRNA and evaluated in HSPCs isolated from FA mice. Following confirmation of genetic and functional correction, HSPCs will be transplanted into lethally-irradiated FA mice and subsequently monitored over several weeks for immune reconstitution by peripheral blood mononuclear cell collection and flow cytometry. In pursuit of a more accessible and cost-effective therapy for FA, we will administer the validated polymer-ABE8e complexes to FA mice *in vivo* alongside an adenovirus control delivering the same cargo. If delivery to HSPCs is successful, we expect to recover mitomycin C (MMC)-resistant cells from peripheral blood and marrow within 16 weeks. At the endpoint, bone marrow will be collected for genomic sequencing and flow-sorted to isolate Lin- c-Kit+ Sca1+ HSPCs for further study. To confirm restoration of function, we will perform Western blot for FANCA, culture these cells in the presence of MMC to determine their ability to perform interstrand crosslink repair, and measure the monoubiquitination of FANCD2 by Western blot. This work will validate the *in vivo* correction of the *FANCA* Spanish founder mutation and lay the groundwork for non-viral gene therapy for FA patients.

Figure 1: Schematic representation of initial polymer screening.



638 Demonstration of Human Factor VIII Expression and Activity Following Single and Repeat Dosing of a Non-Viral Integrating Gene Therapy

Espinoza[1], Michelle Burrascano[1], James Yen[1], Kevin Briseno[1], Min Tong[1], Jen Beck[1], Joseph Lucas[1], Pavan Battiprolu[1], Mike Bennett[1], Blair Madison[1], Brent Warner[1], Eric Ostertag[1], Joshua Rychak[1]

[1]Poseida Therapeutics, San Diego, CA,[2]Takeda Therapeutics, Boston, MA,[3]Takeda, Cambridge, MA

The current first-line treatments for Hemophilia A patients are clotting factor replacement and/or bi-specific antibodies. These treatments require continuous, lifelong infusions, yet many patients have breakthrough bleeds. There remains a high unmet need for safe, effective, and durable therapies. We evaluated the potential of a liver-directed non-viral in vivo gene insertion approach using the super piggyBac® DNA insertion system to produce stable human FVIII (hFVIII) expression in mice. Unlike conventional AAV-based gene therapy approaches, our platform enables delivery of large transgenes, the ability to stably and safely integrate the therapeutic transgene into the genome, and the potential for re-dosing to titrate to target FVIII activity. We first developed a dual liver-tropic nanoparticle system that entails one lipid nanoparticle (LNP) encapsulating the super piggyBac transposase (SPB) formulated as mRNA (LNP-SPB), and a second LNP encapsulating the transposon formulated as plasmid DNA and comprising the hFVIII open reading frame, a promoter, and super piggyBac inverted terminal repeats (LNP-hFVIII).To validate the durability of this system, mice were dosed intravenously with the two individual LNP formulations, each optimized for either the delivery of the SPB mRNA or the therapeutic hFVIII transposon DNA cassette. We observed durable and dose-dependent hFVIII expression in these models of dividing liver significantly above normal levels. To further support the concept of re-dosing, we treated wild type mice up to 4 times and observed a dose-proportionate increase in hFVIII antigen levels after each administration. We subsequently evaluated a co-encapsulated LNP formulation, comprising both SPB mRNA and transposon plasmid DNA in the same liver-tropic nanoparticle in juvenile Hemophilia A mice and observed a ~50% increase in hFVIII antigen expression compared to the dual nanoparticle approach. No evidence of persistent liver enzyme elevation was observed following treatment. To validate the co-encapsulated nanoparticle approach, we performed a study in a mouse model of severe hemophilia A (FVIII knock-out) tolerized to prevent immune response against human FVIII. Following a single dose in adult mice, we observed ~30% hFVIII expression sustained over the duration of the study. The integration profile was assessed, and no insertions were found within tier 1 or tier 2 COSMIC tumor suppressor genes. Our results demonstrate the capabilities of the super piggyBac DNA insertion system and non-viral approach in providing stable FVIII transgene expression through

genomic integration, along with the potential for redosing. These data provide proof-of-principle toward developing a potential functional cure for Hemophilia A.

639 A New Liver-Humanized Mouse Model for the Study of Hepatitis B Virus and Human Hepatic Gene Editing

Daniel Stone[1], Rosanna Colon-Thillet[1], Michelle A. Loprieno[1], Lindsay Klouser[1], Pavitra Roychoudhury[2], Tracy K. Santo[2], Hong Xie[2], Laurence Stensland[2], Sarah Upham[2], Greg Pepper[2], Meei-Li Huang[2], Martine Aubert[1], Keith R. Jerome[3]

[1]Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA,[3]Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Research Center, Seattle, WA

Liver-humanized mice are a powerful tool for drug metabolism and pharmacokinetics studies, for the study of hepatotropic infectious agents such as hepatitis B virus (HBV), hepatitis C virus (HCV), and malaria, and for the study of hepatic human gene editing *in vivo*. However, the commercial cost and complexity of existing liver-humanized mouse models including uPA-SCID, TK-NOG, and FRG mice has limited their widespread use in academic research. To establish a cost-effective model that we could use for the study of HBV, hepatic gene transfer, and human hepatic gene editing, we evaluated the recently described liver humanized NSG-PiZ mouse model that is relatively inexpensive and easy to establish. Since HBV is extremely species-restricted, we first challenged liver-humanized NSG-PiZ mice with HBV, a pathogen of major public health importance that is largely incurable once a chronic infection is established, to determine whether they are also permissive to HBV replication. After administration of a genotype D clinical isolate, chronic infections lasting at least 6 months could be established, and we were able to serially passage virus through 3 generations of mice without loss of viral fitness. HBV selectively replicated in hCK18+ human hepatocytes and HBV+ mice had viral loads and HBsAg levels in blood comparable to those seen in patients not receiving antiviral therapy. Importantly, livers of HBV+ mice harbor covalently closed circular DNA (cccDNA), the template for viral replication, enabling the study of curative antiviral therapies that target cccDNA. We next showed that HBV+ liver-humanized NSG-PiZ mice can be used to evaluate antiviral therapies by treating HBV+ mice with the reverse transcriptase inhibitor entecavir, a frontline antiviral agent used to treat HBV+ patients. Over 4 weeks of entecavir therapy, viral loads decreased by approximately 3 logs compared to untreated mice, then rebounded after entecavir withdrawal. We finally showed that HBV- and HBV+ human hepatocytes can be efficiently transduced by AAV-vectors *in vivo*, which should enable the delivery of antiviral gene therapeutics or gene editing reagents that target HBV or human hepatic genes. HBV+ NSG-PiZ mice were administered AAV vectors packaged with the hepatotropic AAV3b and AAV.LK03 vector capsids and gene transfer was analyzed at 4 weeks post vector administration. While both vector capsids mediated transduction of both mouse hepatocytes and human hepatocytes, AAV.LK03 preferentially transduced human hepatocytes with high efficiency, which should enable the study of curative gene therapies targeting chronic HBV or hepatic human gene editing. In summary, we have established a robust and cost-effective model for HBV that can be used as an alternative to existing models in the study of established and new therapeutic approaches targeting chronic HBV infections. Our model may also be used to study human hepatic gene editing *in vivo* since human hepatocytes can be readily targeted by AAV vectors.

640 Transcriptomic Profiling of Glycogen Storage Disease Type IX γ2 Mouse Liver and Matched Plasma to Identify Biomarkers for Gene Therapy

Sasha C. Makohon-Moore[1], Russell Buchanan[1], Jeong-A Lim[2], Su Jin Choi[2], Rebecca L. Koch[2], Priya S. Kishnani[2], Chari Smith[1], Jennifer Israel[1]

[1]Kriya Therapeutics, Inc., Research Triangle Park, NC,[2]Duke University Medical Center, Durham, NC

The understanding of gene expression pathway changes and the identification of potential biomarker expression can further our understanding of gene interactions, provide critical exploratory endpoints for gene therapy treatment, and support clinical development. Availability of this data for rare diseases is limited by the relatively small investment in research on the disease natural history. Glycogen storage disease (GSD) type IX is caused by deficiency in phosphorylase kinase (PhK), the enzyme that initiates glycogenolysis. PhK in the liver is comprised of four subunits: α2, β, γ2, and δ. Biallelic pathogenic variants in the gene encoding the γ2 subunit (PHKG2) causes GSD IX γ2 in which affected patients are unable to breakdown glycogen in the liver and exhibit fasting ketotic hypoglycemia, hyperlipidemia, altered LDL/HDL cholesterol ratios, and progressive liver fibrosis with risk for cirrhosis. We identified metabolic pathway changes and potential biomarkers for GSD type IX γ2 using transcriptomic profiling of a Phkg2 knock-out (KO) mouse model during a critical period of disease pathophysiology development. In this study, we obtained WT and KO mouse liver and plasma samples at 4, 6, 8, and 12 weeks of age. Following mRNA and small RNA extraction from liver and plasma, respectively, we prepared libraries using an Illumina Stranded mRNA kit and PerkinElmer Nextflex small RNA-Seq v4 kit and sequenced these on an Illumina NextSeq 2000. Our results reveal that genotype explains the highest proportion of transcriptomic variation, followed by the age of the mouse, for both the liver mRNA and plasmid small RNA samples. In the liver, there are striking changes in the expression levels of key enzymes involved in glycogen synthesis and glycogenolysis including Gys2 and Pygl, respectively. Markers of liver fibrosis and inflammation, such as Smad7, Ccl2, and Itgb5, are increased in the KO livers relative to WT, specifically at later time points. The expression of several lipid metabolic enzymes also differed in the livers of WT and KO animals. These results are mirrored in our analysis of matched plasma samples, in which we observed significant differences in the expression of liver-specific microRNAs in plasma from KO compared to WT animals, including the well-studied miR-122-5p, which has been associated with an adverse metabolic profile in the liver. This study provides the first transcriptomic analysis of a GSD IX γ2 mouse model and allows for the identification of potential hepatic metabolic changes and biomarkers that vary across the natural course of the disease in both liver and plasma, improving our understanding of disease mechanisms. These biomarkers will be critical for assessing the impacts of therapy

interventions on liver fibrosis and metabolic function restoration in the GSD IX γ2 mouse model and will be pursued as exploratory endpoints for future clinical studies in patients treated with gene therapy.

641 Co-Formulation of Peptide Dendrons with Liposomes for Liver Delivery of mRNA and DNA

Hannah Vaughan, Morgan Urello, Andrew Ciciriello, Yuan Rui, Lance Dockery, Ronald Christie
Biologics Engineering, AstraZeneca, Gaithersburg, MD

Nucleic acid therapies have the potential to treat or even cure a wide range of diseases through knockdown, expression, and/or editing of target genes. However, achieving efficient, safe, and selective delivery of nucleic acid cargoes remains a challenge. In this work, we investigated nanoparticle-based methods to deliver DNA and mRNA to the liver. Proprietary lysine-based peptide dendrons (PDs) were used to condense DNA or mRNA into nanoparticles in the presence of DOPE/DOTMA liposomes (Lipofectin®), resulting in a peptide-lipid coformulation. PDs were further modified with N-Acetylgalactosamine (GalNAc) ligands to enhance delivery to liver *in vivo* via the asialoglycoprotein receptors (ASGPR) expressed on hepatocytes. Peptide dendrons and Lipofectin® were combined at varying ratios before mixing with nucleic acid and allowed to self-assemble into nanoparticles in aqueous buffer. The resulting nanoparticles were 150-200 nm in diameter with spherical morphology. DNA and mRNA cargoes encoded for luciferase were used to track expression in mice by IVIS bioluminescence imaging following tail vein injection. Peptide dendrons and Lipofectin® were shown to act synergistically, significantly enhancing liver expression of DNA and mRNA over peptide dendrons or liposomes alone. Additionally, we observed an increase in transfection with increasing GalNAc density, showing that transfection was driven by specific interactions between GalNAc targeting ligands and ASGPR expressed on hepatocytes. This platform also showed differences in expression kinetics for mRNA and DNA cargoes. Cargo selection significantly impacted expression kinetics; mRNA showed strong transient liver expression for 48 hours, while DNA expression was sustained for over 20 days. Taken together, these results show that targeted peptide dendron-liposome co-formulations are a promising and versatile platform for nucleic acid delivery to liver.

642 Liver-Directed Gene Therapy for Ornithine Aminotransferase Deficiency

Iolanda Boffa[1], Elena Polishchuk[1], Lucia De Stefano[1], Fabio Dell' Aquila[1], Edoardo Nusco[1], Elena Marrocco[1], Matteo Audano[2], Pedretti Silvia[2], Marianna Caterino[3,4], Ilaria Bellezza[5], Margherita Ruoppolo[3,4], Nico Mitro[2,6], Barbara Cellini[5], Alberto Auricchio[1,7], Nicola Brunetti-Pierri[1,8,9]

Gyrate atrophy of choroid and retina (GACR) is a chorioretinal degeneration caused by pathogenic variants in the gene encoding ornithine aminotransferase (OAT), an enzyme mainly expressed in liver. Affected patients have increased ornithine concentrations in blood and other body fluids and develop progressive constriction of vision fields leading to blindness. Current therapies are unsatisfactory and better treatments are highly needed. In two mouse models of OAT deficiency that recapitulates biochemical and retinal changes of GACR, we investigated the efficacy of an intra-venously injected serotype 8 adeno-associated (AAV8) vector expressing OAT under the control of a hepatocyte-specific promoter. Following injections, OAT-deficient mice showed reductions of ornithine concentrations in blood and eye cups compared with control mice injected with a vector expressing green fluorescent protein. AAV-injected mice showed improved electroretinogram response and partial restoration of retinal structure up to one-year post-injection. In summary, hepatic OAT expression by AAV8 vector was effective at correction of hyperornithinemia and improved function and structure of the retina. In conclusion, this study provides proof-of-concept of efficacy of liver-directed AAV-mediated gene therapy of GACR.

643 *In Vivo* Gene Therapy for Lysosomal Acid Lipase Deficiency

Marine Laurent[1], Christine Jenny[1], Julie Oustelandt[1], Anaïs Brassier[2], Francesca Landini[3], Consiglia Pacelli[3], Giuseppe Ronzitti[1,3], Mario Amendola[1,3]
[1]UMRS_951 Genethon, Evry, France,[2]Necker-Enfants-Malades University Hospital, Paris, France,[3]Department of Clinical and Experimental Medicine, University of Foggia, Foggia, Italy

Lysosomal acid lipase deficiency (LAL-D) is an autosomal recessive disorder caused by mutations in the *LIPA* gene. LAL enzyme is involved in lysosomal hydrolysis of cholesterol esters and triglycerides and its deficiency triggers fats accumulation leading to multi-organs failure. The most severe form of LAL-D (Wolman disease, WD; ≤5% residual

LAL activity) affects ~1/300,000 live births and, if not treated, results in premature death within the first year of life due to denutrition and hepatic insufficiency. Enzyme replacement therapy (ERT) is the only available supportive treatment and consists in weekly systemic injection of recombinant LAL. Although life-saving, ERT is not curative and is associated with the risk of developing neutralizing antibodies that can decrease treatment efficacy. In order to develop a curative treatment for WD, we first characterized a new *lal*$^{-/-}$ mouse model and then assessed a gene therapy treatment based on the *in vivo* administration of recombinant AAV vector encoding human LAL. The full *lal*$^{-/-}$ mouse model was generated by deleting the exon 4 of the *LIPA* gene. We confirmed the loss of LAL protein and activity and the accumulation of cholesterol and triglycerides in liver, spleen, and jejunum. Lipid overload in the liver leads to an increase in liver transaminase and a change in the blood lipid profile, in particular HDL decrease. Moreover, *lal*$^{-/-}$ mice display a dysregulation in haematological compartment, with an inflammatory profile associated with an increase of granulocytes, monocytes/macrophages and platelets and a decrease of lymphoid population. We are currently investigating the effect of LAL deficiency on cellular metabolism and mitochondria. For gene therapy, we decided to target the liver by systemically injecting 3-month-old *lal*$^{-/-}$ mice using the AAV-8 serotype encoding the hLAL gene under the control of hepatocyte-specific human α1-antitrypsin (hAAT) promoter. Modified hepatocytes would both produce LAL to correct their own metabolic impairment and secrete the enzyme in bloodstream to cross-correct affected tissues. Starting from two weeks after injection, we restored LAL expression/activity in plasma and we observed a therapeutic effect in term of haematological parameters, decrease of hepatic transaminase and normalization of HDL profile. At 3- and 10-months post-injection, we sacrificed mice, and we analysed tissue correction by histological staining, cholesterol/triglycerides quantification, and measurement of LAL enzymatic activity. Assessment of mitochondrial function is currently under investigation. To decrease vector dose and maximize the therapeutic benefit of our *in vivo* gene therapy strategy, we engineered *LIPA* cDNA to improve LAL expression and secretion in cells (~10x) by optimizing the codon usage and changing its signal peptide sequence and we are currently evaluating its therapeutic benefit *in vivo*. Overall, our *in vivo* gene therapy strategy appears to be an effective approach to achieve stable LAL expression to correct WD disease phenotype in a relevant *lal*-/- mouse model. Therefore, the development of such AAV-based gene therapy would offer a curative treatment of LAL-D patient improving their life expectancy and quality.

644 Selective Expansion of Transplanted Hepatocytes Corrects a Mouse Model of Phenylketonuria

Anne Vonada, Amita Tiyaboonchai, Cary O. Harding, Markus Grompe

Oregon Health and Science University, Portland, OR

Phenylketonuria (PKU) is an autosomal recessive inborn error of metabolism caused by a deficiency in the enzyme phenylalanine hydroxylase (PAH). PAH is responsible for the metabolism of phenylalanine (Phe) to tyrosine in hepatocytes. In the absence of PAH, highly elevated Phe levels in the blood lead to severe neurological symptoms unless patients maintain a highly restricted diet. Several AAV gene therapy approaches are in development for PKU. However, these treatments are predicated to be of limited efficacy for pediatric patients as cell division in the growing liver leads to episome loss. An alternative strategy for permanent correction of PKU is hepatocyte transplantation, a cell therapy method wherein donor hepatocytes are delivered into circulation where they engraft in the recipient liver and support liver function. A limitation of this method is the low rate of engraftment of the delivered cells. This problem could be overcome by selectively expanding the transplanted cells until they make up enough of the liver to correct blood Phe levels. We have previously reported a system to expand gene edited hepatocytes in vivo using the common fever medication acetaminophen (APAP). This is accomplished by knocking out the gene cytochrome P450 reductase (Cypor), which is required for the metabolism of APAP into its hepatotoxic metabolite. Thus, when the liver is treated with high levels of acetaminophen, Cypor deficiency confers a survival advantage and these cells expand to repopulate the liver. We have previously presented proof-of-concept for the correction of PKU using this selection system, and here we report robust correction with long term follow-up. Primary hepatocytes were isolated from a wildtype mouse and treated in vitro with Cas9 ribonucleoprotein complexes to create a knockout of the Cypor gene. Hepatocytes were delivered to *Pah*-deficient mice, which were subsequently treated with an APAP-containing diet. Correction of blood Phe levels to within the physiological range was achieved in both male and female animals, and in multiple strains of *Pah*-deficient mice. This correction was sustained for >250 days after discontinuing APAP treatment. Upon harvest, clonal expansion of Cypor-deficient hepatocytes was observed in APAP-treated mice. By comparison, animals that received a hepatocyte transplant without APAP selection showed only rare transplanted cells equivalent to <1% of the liver mass and no reduction in blood Phe. Analysis of insertion/deletion mutations at the Cypor-targeted guide RNA locus in the APAP-treated corrected animals indicated approximately 15% Cypor deficient hepatocytes, corresponding to the threshold of *Pah*-expressing hepatocytes required to correct the PKU phenotype. Compared to a known maximum of >40% Cypor-deficient hepatocytes that can be achieved with the APAP selection system, this indicates that a majority of susceptible hepatocytes retain Cypor activity. This mitigates concerns that partial Cypor deficiency will lead to unintended consequences. To further examine the effects of partial Cypor deficiency, metabolism of a Cypor-metabolized drug will be assessed in selected animals. The data presented here indicate that hepatocyte transplantation with the APAP selection system is a potential therapeutic for the complete, long-term correction of PKU. This strategy has potential applicability to a variety of inborn errors of metabolism.

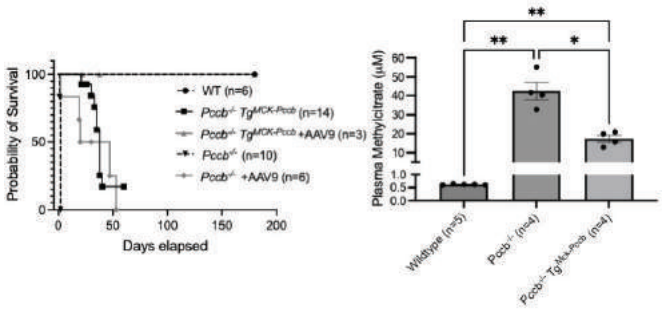
645 Versatile Knock-Out and Transgenic Murine Models of *PCCB* Deficiency Enable the Testing of Systemic AAV Gene Delivery as a Treatment for Propionic Acidemia

Randy J. Chandler, Charles P. Venditti

National Institutes of Health, Bethesda, MD

Propionic acidemia (PA) is rare autosomal recessive metabolic disorder caused by defects in the mitochondrial localized enzyme propionyl-CoA carboxylase (PCC). The PCC enzyme is composed of six nuclear encoded α- and six β-subunits with causative variants in either of the *PCCA* or *PCCB* genes found at equal frequencies.

Individuals with PA can suffer from lethal metabolic instability and cardiomyopathy despite medical management, which has provided a strong rationale to develop gene therapy as a possible treatment option for patients. There are no publications which describe murine models of PCCB deficiency or the development of gene therapy for this subtype of PA. We have therefore developed new murine models of PCCB deficiency, one severe and another milder, and tested AAV gene therapy as a treatment in the mice. CRISPR-Cas9 gene editing targeting the 14th exon of the murine *Pccb* gene was used to introduce a 4 base pair deletion (c.1492_1495delCCAG), predicted to result in a frameshift stop mutation (p.A489Pfs*1). Mice homozygous for this mutation ($Pccb^{-/-}$) display a neonatal lethal phenotype with 100% of the affected mice perishing in the first 72 hours of life and manifest massively elevated plasma 2-methycitrate levels in the plasma. In a proof-of-concept study, $Pccb^{-/-}$ mice treated at birth with 6.6e14 vg/kg of AAV9.CAG.PCCB, delivered by retroorbital injection, had a significant increase in survival in comparison to untreated mutant controls ($p<0.01$). Due to the severe lethality displayed by the $Pccb^{-/-}$ mice, we designed a germline transgene to express the murine *Pccb* cDNA under the control of a muscle specific promoter ($Tg^{MCK\text{-}Pccb}$) and through breeding generated $Pccb^{-/-}$ $Tg^{MCK\text{-}Pccb}$ mice in order to assess clinical and biochemical effects on the severe PA phenotype of the $Pccb^{-/-}$ mice. The resultant $Pccb^{-/-}$ $Tg^{MCK\text{-}Pccb}$ mice display increased survival, growth retardation, and moderate elevations of plasma methylcitrate in comparison to the $Pccb^{-/-}$ mice without the transgene. To test the utility of the $Pccb^{-/-}$ $Tg^{MCK\text{-}Pccb}$ mice to evaluate new therapies, we treated mutant mice at 30 days with a dose 1e14 vg/kg of AAV9.CAG.PCCB delivered by retroorbital injection and observed a significant increase in survival in comparison to untreated controls ($p<0.02$). These new murine models of PA span the clinical spectrum of severity, manifest cardinal clinical and biochemical features of PCCB deficiency, and can be used to test the effects of new genomic therapies for PA, including AAV9 gene therapy.



646 A Mouse Model Resource to Test Gene and Cell-Based Therapies for Peroxisomal Disorders

Joseph G. Hacia[1], Lauren T. Arayan[2], Nancy E. Braverman[3], Aamir R. Zuberi[2]

[1]Biochemistry and Molecular Medicine, University of Southern California, Los Angeles, CA,[2]The Jackson Laboratory, Bar Harbor, ME,[3]Research Institute of the McGill University Health Centre, McGill University, Montreal, QC, Canada

Peroxisomes are metabolic organelles that serve as a central hub of cell signaling pathways and play essential roles in the development and functions of all organ systems. Peroxisome dysfunction is causally responsible for a group of rare monogenic disorders including X-linked adrenoleukodystrophy, Zellweger spectrum disorder, D-bifunctional protein deficiency, and adult Refsum disease. They also contribute to the pathophysiology of a diverse group of common disorders including diabetes, cancer, and Alzheimer's disease as well as a host of infectious diseases. They contact and exchange materials with other organelles and are thus critical for cellular metabolism. Despite their relevance to numerous facets of human health and disease, the limited number of well-annotated publicly available mouse models and immunological resources required to investigate various aspects of peroxisome biology and test gene and cell-based therapies has hindered the biomedical research community. Moreover, the impact of many existing mouse models has been lessened since they often are placed on suboptimal genetic backgrounds or are not readily available to the public. Here, we have established the Mouse Peroxisome Research Resource (MPRR) that will provide a central resource for mouse models and monoclonal antibodies for basic and translational research relevant to peroxisome biology and disorders caused by peroxisome dysfunction. The MPRR is a community-driven effort that leverages a world-leading knowledge of mouse genetics, gene editing, and monoclonal antibody production capability as well as expertise in model development and disease model repositories to accelerate the creation, distribution, and proper use of high-impact mouse models and monoclonal antibody reagents. The MPRR will ensure that all deposited mouse models are on standardized genetic backgrounds to control for the presence of genetic modifiers. These strains will be made available as well-annotated resources with as few legal restrictions as possible. The MPRR will also produce novel high-priority mouse models with defined genotypes on standardized genetic backgrounds, cryopreserve them, and distribute them to the public. Moreover, the MPRR will also assist in the targeted phenotyping of these models, including measurement of relevant peroxisomal metabolite levels. Furthermore, the MPRR will produce and publicize and distribute validated monoclonal antibody reagents for peroxisome research, including characterizing relevant mouse models. Overall, the MPRR will dramatically increase the number of available mouse models and monoclonal antibody reagents based on community-driven priority and accelerate preclinical testing of rationally designed cell and gene-based therapeutic interventions for disorders caused by peroxisome dysfunction.

647 Therapeutic Efficacy of VTX-801 in Advanced Stage of Wilson's Disease in Mice

Oihana Murillo[1], Cristina Gazquez[2], Daniel Moreno-Luqui[2], Miren Barberia[2], Blanche Tamarit[3], Anne M. Douar[3], Bernard Benichou[3], Jean-Philippe Combal[3], Ruben Hernandez-Alcoceba[4], Veronica Ferrer[3], Gloria Gonzalez-Aseguinolaza[5]

[1]Gene Therapy, Cima Universidad de Navarra, Pamplona, Spain,[2]Gene therapy, Cima Universidad de Navarra, Pamplona, Spain,[3]Vivet Therapeutics, Paris, France,[4]FIMA Center for Applied Medical Research, Pamplona, Spain,[5]Gene Therapy, Vivet Therapeutics, Pamplona, Spain

Wilson's disease (WD) is a rare disorder of copper metabolism inherited in an autosomal recessive manner. It is due to missense mutations in *ATP7B*, a copper-transporting P-type ATPase, that lead to hepatic, neurologic, or psychiatric symptoms. Left untreated, the condition progresses to severely debilitating complications and death. VTX-801 is a recombinant adeno-associated vector (rAAV) carrying a shortened version of the human *ATP7B* gene. VTX-801 has demonstrated to provide long-term correction of copper metabolism and ceruloplasmin levels, preservation of liver integrity and function when administered at early stage of the disease in WD mice. Based on these results, GATEWAY, a phase I/II clinical trial was initiated to evaluate VTX-801 in adult patients with WD. To extend previous results, we assessed the therapeutic efficacy and safety of VTX-801 in advanced stage disease WD mice by administering a dose defined as therapeutic in younger animals.[1] Thus, a single dose of VTX-801 was injected to 12-, 16- & 20-week-old WD mice, presenting with progressive liver abnormalities including inflammatory foci, single cell necrosis and hepatocyte hypertrophy. VTX-801-treatment outcome was assessed 6 months later by measuring copper metabolism parameters, liver injury and function, hematological parameters, liver histology, and liver transgene expression and transduction. Although most of pharmacodynamic effects of VTX-801 observed in younger mice were retained -urinary copper excretion rate remained relatively low, liver function (albumin, cholesterol and glucose) improved and tissue (brain, kidney and liver) copper content reduced compared to untreated animals-, certain liver histological features such as fibrosis were not fully reversed in older animals. The quantification of viral genome copies and transgene expression in livers of WD mice treated at 12 weeks of age confirmed the persistence of the viral genomes and the sustainability of transgene expression at time of sacrifice. However, lower transduction efficiency might explain the reduction in therapeutic effect observed in older animals. These results demonstrate that VTX-801 can slow down Wilson's disease progression by improving major pathological features of the disease and may represent a promising treatment also for late stage of this condition in WD patients.

1 Murillo O, et al. Liver Expression of a MiniATP7B Gene Results in Long-Term Restoration of Copper Homeostasis in a Wilson Disease Model in Mice. Hepatology. 2019 Jul;70(1):108-126. doi: 10.1002/hep.30535. Epub 2019 Mar 20. PMID: 30706949.

648 Codon-Optimization Enhances the Expression/Secretion of rSGSH, and Functional Benefits to Treat MPS IIIA in Mice via Systemic scAAV9-h*SGSH*^{op} Gene Delivery

Tierra A. Bobo[1], Hyouk-Bum Kwon[2], Laura Montes[2], Christopher Tofade[2], Preston Samowitz[2], Haiyan Fu[1]

[1]Peds-Genetics and Metabolism, University of North Carolina, Chapel Hill, NC,[2]Gene Therapy, University of North Carolina, Chapel Hill, NC

Mucopolysaccharidosis (MPS) IIIA is a devastating neuropathic lysosomal storage disease caused by autosomal recessive defects in sulfoglucosamine sulfohydrolase (SGSH). No treatment is available for MPS IIIA. To address the unmet need, we developed a new scAAV vector to deliver the codon-optimized human SGSH gene (h*SGSH*^{op}), driven by a truncated mini CMV (mCMV) promoter. *In vitro* studies showed that the scAAV-h*SGSH*^{op} vector enhanced the expression and more importantly the secretion of rSGSH. We tested the vector in 1-2m-old MPS IIIA mice with a single IV injection of scAAV9-h*SGSH*^{op} vector at doses 4e12vg/kg - 8e13vg/kg. The results showed that the vector treatments led to in rapid and persistent restoration of SGSH activity and the clearance of lysosomal storage pathology throughout the CNS, peripheral nervous system (PNS) and broad peripheral tissues. Importantly, behavior testing in Morris water maze at 7m pi showed significant improvement in learning and swimming ability in the vector treated MPS IIIA mice. Further, the majority of MPS IIIA mice treated with the vector survived within the normal life span. These data indicate the functional correction of neurological manifestation. The vector treatments did not result in any detectable adverse events or systemic toxicity in MPS IIIA mice. In this study, we have developed a new effective and safe gene replacement therapy product, supporting the promising clinical potential of systemic scAAV9-h*SGSH*^{op} gene delivery for treating MPS IIIA in humans.

649 Hematopoietic Stem Cell Gene Therapy for Mucopolysaccharidosis Type IIIC

Rafael A. Badell-Grau[1], Anusha Sivakumar[1], Veenita Khare[2], Kalvin Duong[1], Pauline Losay[1], Kasra Pakravesh[1], Christine Tran[1], Rushil Pithia[1], Mira Lengsfield[1], Kevin Thai[1], Jay Sharma[1], Rola Chen[1], Joseph N. Rainaldi[1], Stephanie Cherqui[1]

[1]University of California, San Diego, La Jolla, CA,[2]University of California, San Diego, San Diego, CA

Mucopolysaccharidosis type IIIC (MPSIIIC) is a severe progressive childhood neurodegenerative disease caused by loss-of-function of the transmembrane lysosomal protein Heparan-α-glucosamine N-acetyltransferase (HGSNAT). MPS IIIC is part of the lysosomal storage disease (LSD) family and is characterised by the accumulation of glycosaminoglycans (GAGs). This disease has no available treatment and presents early in life with symptoms like missing developmental milestones, neuronal cell loss and loss of motor function, eventually leading to death around the second or third decade of life. Our lab has previously shown that transplantation of hematopoietic stem and progenitor cells (HSPCs) rescue cystinosis, another LSD due to mutations in a transmembrane lysosomal protein. The mechanism of rescue involved lysosomal cross-correction from HSPC-derived macrophages to the disease cells via tunnelling nanotubes within tissues.

We believe that the same principles could be used to treat MPSIIIC. We generated a new MPSIIIC mouse model by knocking-out exon 2 in *Hgsnat*. We have confirmed the presence of MPSIIIC disease phenotypes such as GAG accumulation, enlarged liver, distended bladder, urine retention, lysosomal expansion, neurological defects, increased inflammation, and the presence of disease specific non-reducing end carbohydrates biomarkers in our mouse model. As the first proof of concept, we transplanted *Hgsnat*$^{-/-}$ mice with HSPCs isolated from WT GFP-transgenic mice. Even though we see engraftment of HSPC-derived cells, tissue expression of *Hgsnat* was low and no reduction in GAG storage was observed in the transplanted mice. These data demonstrate that endogenous *Hgsnat* is not well expressed in HSPC-derived macrophages/microglia explaining the limited impact of WT-HSPC transplant on GAGs. Nonetheless, WT-HSPC transplant did show improvement in hepatomegaly, urine retention, neurological defects, and gait defects, which correlates with decreased inflammatory markers in the treated *Hgsnat*$^{-/-}$ mice. Limited efficacy of WT-HPSCs has also been reported in MPSIIIA, which was overcome by using gene-modified HSPCs to overexpress *SGSH* gene. Therefore, we are developing an autologous transplantation of ex-vivo gene modified HSPCs. We have generated self-inactivated (SIN)-lentivirus vector containing human *HGSNAT* cDNA (NM_152419 & XM_005273411.2) and performed *in vitro* testing. Following transduction of mice fibroblasts, human patient fibroblasts and human patient B-lymphoblast, we observed increased human *HGSNAT* mRNA expression, lysosomal localisation of HGSNAT, recovery of HGSNAT enzyme activity, decreased GAG storage, and decreased lysosomal accumulation. We also transplanted gene-modified HSPCs in *Hgsnat*$^{-/-}$ mice, and have confirmed engraftment of our treated mice at 2 months post-transplantation. The results of the *in-vivo* transplants on GAG storage, behavioural outcome, and histological anomalies will be presented at the conference.

650 Enhanced Long-Term Efficacy of an AAV-PAH Vector for Treating Phenylketonuria

Shengmei Wen[1], Zhiyong Cao[1], Yufeng Guo[1], Minjun Guo[1], Biao Wang[1], Weimin Guo[1], Yiting Liu[2], Guang Qu[1,2], Lixin Jiang[1,2]

[1]NGGT (Suzhou) Biotechnology Co., Ltd., Suzhou, China,[2]NGGT Inc, Walnut Creek, CA

Introduction: Phenylketonuria (PKU), also known as Phenylalanine hydroxylase (PAH) deficiency, is a rare autosomal recessive inherited disorder of phenylalanine (Phe) metabolism, most commonly caused by pathogenetic variants in the *PAH* gene. Hepatic PAH is responsible for the conversion of Phe to tyrosine (Tyr). Deficiency of PAH activity results in hyperphenylalaninaemia (HPA), that is Phe accumulation in the blood and lack of Tyr, and subsequently abnormal brain development in childhood, psychiatric and cognitive problems in adults. The outcomes of current dietary restriction treatment are still suboptimal and pharmacological approaches have drawbacks. The ideal therapy would stably restore PAH activity in the liver and provide a cure for PKU. Several different AAV-mediated *PAH* gene transfer strategies have been developed. However, none of them is successful due to the safety concerns associated with the high doses. **Methods/Results:** By combining an AAV vector with high tropism for liver and an optimized expression cassette, we have developed NGGT002, an rAAV8-based vector expressing human PAH (rAAV8-hPAH). In HepG2 cells with AAV receptor (AAVR) overexpression, a dose-dependent reduction of Phe concentration was observed, indicative of an effective *in vitro* biopotency of hPAH activity of NGGT002. In PKU mouse model maintained on a Phe-containing normal chow diet, complete and sustained correction of HPA phenotypes, such as reduced blood Phe level, increased body weight, darkened coat color and restored brain 5-hydroxyindoleacetic acid (5-HIAA) and Tyr concentration, was observed up to 40 weeks following a single intravenous (IV) injection of NGGT002. Maximal and stable therapeutic effects were achieved at the doses of 1e12 vg/kg in male and 2e12 vg/kg in female PKU mice, much lower than the effective doses reported so far. Robust liver transduction and hPAH expression mediated by NGGT002 were detected in PKU mouse. Furthermore, as assessed by RNAscope in liver samples from single dose NGGT002 IV injected Cynomolgus monkeys on day 56 post administration, *hPAH* expression was detected in approximately 30% of the hepatocytes at the dose of 1.3e13 vg/kg and 50% at 3e13 vg/kg, respectively, demonstrating an effective liver gene transfer and *hPAH* transgene expression in non-human primate (NHP). **Conclusions:** Based on the evaluations in the PKU mouse model, NGGT002 has enhanced effects in correcting HPA phenotypes by effectively expressing hPAH in the liver. In NHP, high level of gene transfer and expression has been achieved. These data suggest that NGGT002 has a substantially improved efficacy and a great potential to safely achieve clinical benefits at a much lower dose for treating PKU patients caused by *PAH* mutations.

651 Silibinin Attenuates Adipose Tissue Inflammation & Reverses Obesity & Its Complications in Diet-Induced Obesity Model in Mice

Mohammad Alsaggar

Jordan University of Science and Technology, Irbid, Jordan

Purpose: To investigate therapeutic outcomes of anti-inflammatory activities of the natural compound Silibinin in reversing diet-induced obesity and its complication in mice. Methods: C57BL/6 male mice were fed a high-fat diet for 8 weeks until development of obesity, and then injected with 50 mg/kg silibinin intraperitoneally twice per week, or vehicle for 8 weeks. While on treatment, mice body weight and food intake were monitored, and glucose tolerance test was performed toward the end of the experiment. Animals were sacrified and serum and tissues were collected for biochemical, histological, and gene expression analysis to assess silibinin effects on adipose inflammation, fat accumulation, liver adipogensis and glucose homesatsis. Results: Silibinin reversed adipose tissue inflammation and adipocyte hypertrophy, and blocked diet-induced weight gain and obesity development without affecting food intake. Silibinin also reversed fatty liver disease and restored glucose homeostasis in treated animlas, and reversed hyperglycemia, hyperinsulinemia and hypertriglyceridemia. Conclusion: This study demonstrated that silibinin as an anti-inflammatory therapy is potential alternative to manage obesity and its related pathologies. In addition, silibinin-based therapies could have a promising potential for clinical applications to manage various inflammation-driven disorders.

652 Comparative Analysis of SubQ vs IP Implanted Hepatocyte-Containing Bioprinted Tissues

Christopher TD Dickman, Zainab Bazzi, Oksana Nemirovsky, Farin V. Livary, Fiona Li, Stephanie A. Campbell, Haley Tong, Simon Beyer, Tamer Mohamed, Sam Wadsworth, Spiro Getsios, Rafal P. Witek
Aspect Biosystems, Vancouver, BC, Canada

Background: Liver transplantation is the standard of care treatment for multiple liver diseases including Acute Liver Failure (ALF) and Urea Cycle Disorders (UCD). While effective, liver transplantation is an invasive surgery with the potential for lifelong complications, including implantation site bleeding, immune suppression, and the potential for new malignancies. As an alternative, some research has been focused on using isolated hepatocytes from livers, unsuitable for transplant, to treat liver diseases. Promising results have been seen in pediatric patients with acute liver failure, where encapsulated hepatocytes are implanted into the intraperitoneal (IP) space to provide a supportive liver function for a limited duration of time. However, it remains to be seen if hepatocyte transplantation can be successful in less invasive surgical sites. The subcutaneous (SubQ) space is comparatively non-invasive, offers larger implant sites, and is less likely to be fouled with the products of liver disease (such as ascites). This study demonstrates that 3D bioprinted tissues containing primary human hepatocytes (PHHs) and mesenchymal stromal cells (MSCs) can be implanted into either the SubQ or IP space of NSG mice with equivalent levels of synthetic function in both implantation sites. **Methods:** Cell spheroids were created by the coaggregation of PHH and MSC cells. Spheroids were then suspended in an alginate-based biomaterial. Aspect Biosystems' microfluidic 3D bioprinter was used to make coaxial 'core-shell' fibre tissues, where a cell-containing core was surrounded by a protective shell material. Liver tissues containing 1 million PHHs and 1 Million MSCs were implanted into the IP or SubQ space of immunodeficient NSG mice. Blood was collected one week prior to implantation and at regular intervals post-implantation. Implanted liver tissue function was assessed using human albumin quantified via ELISA over a period of 35 days. **Results:** Prior to tissue implantation, circulating human albumin levels in NSG mice were below the level of detection. Mice receiving bioprinted liver tissues into the IP space demonstrated plasma human albumin levels of 1137 ng/mL one day after implantation. These levels rose to 1970 ng/mL by week two and subsequently dropped to 1176 ng/mL on week 5. Mice receiving bioprinted liver tissues in the SubQ space had plasma human albumin levels reaching 793 ng/mL by day 1, 1970 ng/mL on week 2, and 2031 ng/mL on week 5. Statistical analysis did not show a significant difference between implantation sites. Mice receiving fibres implanted into the SubQ space had faster closure of the surgical wound and decreased bruising compared to mice with fibres implanted into the IP space. **Conclusion:** 3D bioprinted implantable liver tissues maintained high levels of synthetic function after implantation into the IP or SubQ space of NSG mice over a period of a month. The equivalency in function between implantation sites suggests that minimally invasive surgical options may have several benefits. The SubQ space has the potential to receive larger therapeutic tissues, with more frequent replacement and easier monitoring. The decreased invasiveness of the procedure can make liver cell therapies an attractive option for other non-life-threatening illnesses. Our next goals are to confirm that bioprinted liver tissues implanted SubQ can effectively treat a mouse model of metabolic liver disease, and to examine the function of larger bioprinted tissues within the SubQ space of rats.

653 Liver Directed Lentiviral Gene Therapy Provides Long Term Phenotypic Correction of Methylmalonic Acidemia in a Mouse Model

Elena Barbon[1], Camilla Negri[1], Andrea Raimondi[2], Chiara Simoni[1], Francesca Sanvito[1], Anna Fabiano[1], Fabio Russo[1], Alessio Cantore[1,3]
[1]San Raffaele Telethon Institute for Gene Therapy, IRCCS San Raffaele Scientific Institute, Milan, Italy,[2]IRCCS San Raffaele Scientific Institute, Milan, Italy,[3]Vita-Salute San Raffaele University, Milan, Italy

Methylmalonic acidemia (MMA) is a severe inborn error of metabolism caused by deficiency of methylmalonil-coA mutase (MUT), leading to accumulation of the toxic methylmalonic acid. The significant MMA-related morbidity and mortality in infancy led to perform liver transplantation as elective treatment, and to explore gene therapy in MMA mouse models as an alternative therapeutic option. We exploited lentiviral vector (LV) mediated liver gene therapy, which would potentially allow for a stable gene transfer even in paediatric patients at the first disease stages by virtue of LV genomic integration. We generated and validated LV encoding a human MUT transgene under the control of a hepatocyte-specific expression cassette (LV.MUT). We assessed LV-mediated liver gene therapy in a mouse model of MMA expressing a compensatory MUT transgene in the muscles (MCK-Mut-/-). We intravenously administered 2-week old MCK-Mut-/- mice (n=8) with LV.MUT at a dose of $5x10^{10}$ transducing units (TU)/kg and monitored them for >1 year. The gene therapy resulted in a complete rescue of the survival rate and the growth curve of MCK-Mut-/- animals, comparable to that of wild-type (WT) controls. We observed a rapid and sustained decrease of circulating methylmalonic acid (cMMA; mean of 146 μM and 979 μM in treated vs. untreated animals 12 months post-LV) and a substantial 60-fold reduction in the intrahepatic concentration of methylmalonic acid in treated mice compared to MCK-Mut-/- controls. We achieved efficient LV-mediated liver gene transfer with ~15-20% transduced liver area, as assessed by RNA in situ hybridization (ISH). We observed liver overexpression of MUT in MCK-Mut-/- transduced mice compared to endogenous MUT in the liver of WT mice, as assessed by mRNA and protein analyses. End-point histopathology analysis showed that livers of MCK-Mut-/- untreated mice present with enlargement of hepatocyte with small eosinophilic droplets and autophagic vacuoles, which were not observed in age-matched WT controls or MCK-Mut-/- treated with LV. These data suggest a possible detoxification activity of the corrected hepatocytes over the non-corrected ones. Since MCK-Mut-/- mice display hepatorenal mitochondrial pathology similar to MMA patients, we performed electron microscopy on liver and kidney samples from treated mice, showing rescue of mitochondriopathy in both hepatocytes and epithelial cells of the proximal tubules (median mitochondrial area and shape comparable to that of WT mice). These results correlated with normalization of plasma FGF-21, a key biomarker of the mitochondrial function which is highly dysregulated in MMA (mean of 176 and 2362 pg/ml in treated vs. untreated animals

12 months post-LV). We treated additional MCK-Mut mice at different LV doses (2.5, 5 or 10x10[10] TU/kg) and observed weight normalization at all doses and a dose-dependent reduction of cMMA, which reached a plateau at ~180 μM between the mid and high dose. These data provide evidence for long-lasting therapeutic benefit in MMA mouse model with LV gene therapy.

654 Improving *Ex Vivo* HSPCs Strategy for Pompe Disease: CX3CR1 Intron 4 Targeting as Safe Harbour and Novel Mice Models for Its Preclinical Study

Iris Ramos Hernández[1,2], Noelia Maldonado Pérez[1,3], Manuel Sanchez Martin[4,5], Pilar Muñoz[1,6], Francisco J. Molina-Estévez[1,7], Francisco Martin Molina[1,3]

[1]Genyo, Granada, Spain,[2]Fundación Progreso y Salud. Consejería de Salud y Consumo. Junta de Andalucía, Sevilla, Spain,[3]Universidad de Granada, Granada, Spain,[4]Department of Medicine, Universidad de Salamanca, Salamanca, Spain,[5]Institute of Biomedical Research of Salamanca (IBSAL), SACYL-University of Salamanca-CSIC, Salamanca, Spain,[6]Department of Cellular Biology, Faculty of Sciences., Universidad de Granada, Granada, Spain,[7]Fundación para la Investigación Biosanitaria de Andalucía Oriental (FIBAO), Granada, Spain

Ex-vivo gene therapy success exploiting Haematopoietic Stem Progenitor Cells (HSPCs) for paracrine cross-correction is undeniable, like in the case of the rare pathology of Pompe Disease (PD) using lentiviral vectors. However, the semi-random integrations of these vectors rise many safety concerns. Although genome editing (GE) stands as a safer alternative since we can select the insertion site of the expression cassette; before its translation into clinic there are several drawbacks that need improvements, such as safety, efficient expression of the therapeutic transgene and stem cell repopulation. Furthermore, suitable animal models are required to asses safety and therapeutic efficacy before its translation into clinic. Our GE strategy intends to obtain high levels of the transgene expression on the myeloid linage after HSPCs GE. We successfully targeted the 4[th] intron of CX3CR1 with CRISPR-Cas9 on HSPCs without phenotypic or locus expression alteration, acting as a safe harbour. We designed different AAV6 donor DNA templates including a spleen-focus-forming-virus (SFFV) promoter expressing eGFP as reporter. Unexpectedly, when specific targeted insertion was achieved, we observed increased levels of CX3CR1 protein and mRNA on HSPCs, but not in the colonies from CFU's assays. Withal, neither edited T cells nor THP1 cells showed any CX3CR1 increment after targeted addition. Furthermore, we documented a myeloid skewed expression pattern of our reporter transgene. Our observations suggest that this CX3CR1 increment is restricted to discrete HSPCs stem sub-populations. Interestingly, the increase of CX3CR1 could facilitate chemotaxis of these cells towards inflamed tissues. Preclinical tests on NSG humanized mice were made, and no genotoxic or deleterious effects were identified when using our reporter transgene. Therefore, encouraging the use of CX3CR1 as a safe harbour for targeted insertion on HSPCs. However, future testing of the therapeutic GE strategies for PD present several limitations due to the current PD mice models. As these mice models are immunocompetent, show a mixture phenotype of adult and non-classic infantile onset, lack early mortality and present slower muscle weakness. To address these bottlenecks, we have just engineer two novel PD mouse models using CRISPR-Cas9, which mimic two common PD mutations described on patients: c.525del and c.483dup.

655 Long-Term Effects of Fat-Directed FGF21 Gene Therapy in Aged Female Mice

Jacqueline Anderson[1], W. David Arnold[2], Wei Huang[1], Alissa Ray[3], Gregory Owendoff[3], Lei Cao[1]

[1]Cancer Biology and Genetics, Ohio State University, Columbus, OH,[2]NextGen Precision Health, University of Missouri, Columbia, MO,[3]Neurology, Ohio State University, Columbus, OH

Adipose tissue plays a pivotal role in energy homeostasis and pathologies of metabolic diseases. Aging is associated with an increase in adiposity and a functional decline in muscle. Hormone fibroblast growth factor 21 (FGF21) is increasingly recognized as a promising therapeutic agent for metabolic diseases. Rec2, a novel engineered hybrid serotype, has recently emerged as a main choice of AAV serotypes for targeting adipose tissue in vivo. However, Rec2 also transduces liver. The off-target effects in liver are becoming a challenging issue in AAV application. To achieve lower and safer vector dose, we recently designed a single AAV cis-plasmid harboring dual expression cassettes: one using CBA promoter to drive transgene and another using liver-specific albumin promoter to drive a microRNA targeting WPRE sequence in this cis-plasmid. When packed to Rec2, this dual-cassette vector transduces adipose tissue in a highly selective manner, while significantly restricting off-target transduction of liver. With this fat directed Rec2 dual-cassette vector, we have recently demonstrated that FGF21 gene transfer improved metabolic and immune health in insulin resistant BTBR mouse model. FGF21 has also gained an attention as a longevity associated gene. In this study, we deliver Rec2 dual cassette vector to visceral fat of 17-month-old female mice to investigate 1) can FGF21gene transfer in adipose tissue produce high and sustainable level of serum FGF21, 2) can long term FGF21 gene transfer improve aging-related functional decline. Animals with FGF21 gene delivery displayed a steady, significant lower body weight over 7-month course of the study compared to age-matched control mice. The serum level of FGF21 in the gene delivery mice was almost 100 folds more than that in the control mice. No toxicity was observed in FGF21 gene delivery animal. FGF21 gene delivery reduced adiposity and increased relative lean mass and energy expenditure. However, those changes were not translated into benefits on functional improvement of muscle and liver. Overall, we have demonstrated that a single dose of fat-directed AAV-FGF21 gene delivery can provide a sustainable, high serum level of FGF21 with safe profiles over long time of the period, and mostly influences adipose tissue homeostasis and energy expenditure. High levels of FGF21 alone in aged mice is not sufficient to facilitate liver or muscle functions. **CONFLICT OF INTEREST** L.C. and W.H. are inventors of a patent application related to the liver-restricting AAV vector. L.C. is co-founder of Zvelt Therapeutics. All other authors declare no conflicts of interest.

656 Development of Gene Therapy Vectors for the Treatment of Maple Syrup Urine Disease

Ala'a Siam[1], Zeinab Leila Asgarian[1], Ellie Chilcott[2], Anna Keegan[2], Julien Baruteau[3], Rajvinder Karda[2], Simon Waddington[2], John R. Counsell[1]

[1]UCL Division of Surgery and Interventional Science, University College London, London, United Kingdom,[2]UCL EGA Institute for Women's Health, University College London, London, United Kingdom,[3]UCL Great Ormond Street Institute of Child Health, University College London, London, United Kingdom

There is a significant clinical need for novel therapies targeting inborn errors of metabolism. Perinatal administration could provide early mitigation of developmental complications and enhanced biodistribution to target organs. We are investigating the feasibility of a gene therapy strategy to treat maple syrup urine disease (MSUD), a branched chain amino acids (BCAA) metabolic disorder that is caused by mutations in the branched chain ketoacid dehydrogenase (BCKDH) complex. MSUD is associated with neurological complications, psychiatric manifestations and early death. Current treatments are limited to BCAA dietary restriction, blood transfusion and liver transplantation. We have utilized an MSUD mouse model wherein the mouse *Dbt* (*mDBT*) gene, which encodes a constituent subunit of the BCKDH complex, has been knocked out. We compared adeno-associated virus (AAV) and lentiviral (LV) vectors, administering them once intravenously to newborn homozygous knockout mice. We tested two AAV9 vectors, which encoded the codon-optimized human *DBT* (*hDBT*) coding sequence (CDS) under the control of either a ubiquitous (1.3E11 vg/mouse; n=5) or a liver-specific (1.3E11 vg/mouse; n=9) promoter. We also tested two LVs, containing the liver-specific promoter and codon-optimized versions of either *mDBT* (9E7 TU/mouse; n=7) or *hDBT* (7E7 TU/mouse; n=7) CDS. Treated and control mice were followed for five weeks post-injection, and tissues were collected for vector copy number and mRNA expression analyses. All vectors resulted in significant enhancements in survival of treated mice. The AAVs resulted in more widespread expression across different organs than LVs. The LV encoding *mDBT* achieved the greatest level of hepatic expression. The *hDBT* LV and liver-specific AAV9 resulted in comparable hepatic expression, which was significantly greater than the wildtype *mDBT* level. The ubiquitous AAV9 vector resulted in the lowest hepatic expression among the vectors tested. In conclusion, this study shows that AAVs or LVs have potential application as hepatic gene therapy platforms in this mouse model. Future work will include toxicity studies, as well as comprehensive characterization of metabolic and behavioral correction over a prolonged survival course.

657 Improvement of Progressive Familiar Intrahepatic Cholestasis Type 2 via AAV-Mediated Hepatic BSEP Expression in Mice

Angie Molina[1], Laia Triguero-Motos[2], Manoli Molina[3], Guiomar Perez[3], Blanche Tamarit[4], Céline Bouquet[4], Gloria Gonzalez-Aseguinolaza[5], Cristian Smerdou[6]

[1]Gene Therapy, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona, Spain,[2]Gene Therapy, Vivet Therapeutics, Pamplona, Spain,[3]Gene Therapy, Cima Universidad de Navarra, Pamplona, Spain,[4]Vivet Therapeutics, Paris, France,[5]Vivet Therapeutics, Pamplona, Spain,[6]FIMA, Pamplona, Spain

Progressive familial intrahepatic cholestasis type 2 (PFIC-2) is a rare autosomal recessive disorder caused by mutations in *ABCB11* gene encoding for the liver bile salt export pump (BSEP), responsible for the transport of bile salts (BS) from hepatocytes to the canalicular lumen. BSEP absence or dysfunction results in impaired BS secretion and its accumulation in hepatocytes leading to severe liver damage. PFIC2 patients usually develop symptoms during infancy, including cholestasis, failure to thrive, jaundice, hepatomegaly and severe pruritus. Most develop early fibrosis and end-stage liver disease and have an increased risk of developing hepatocellular carcinoma. Therapeutic approaches include pharmacological management of symptoms, surgical biliary diversion or ultimately liver transplantation, which currently is the only curative option. Adeno associated virus (AAV)-based gene therapy targeting the liver represents a safe and efficient option for PFIC2 patients by restoring long-term hepatic BSEP expression and physiological bile secretion. We first generated and characterized an *Abcb11*$^{-/-}$ mouse model of PFIC2 in a pure C57BL/6 genetic background. Bile salt secretion was dramatically impaired in both sexes with reduced BS levels in the bile and small intestine. Female mice showed a progressive elevation of serum transaminase and bilirubin levels starting at two months of age, while male mice only showed an increase in these biomarkers after six months of age. Hepatomegaly was observed in both genders but was significantly higher in females. Overall, females presented a more severe phenotype and recapitulated the human disease more closely than males. We next assessed the therapeutic efficacy of gene therapy in this PFIC2 mouse model using a liver-tropic AAV8 vector carrying a codon-optimized human BSEP cDNA under the control of a liver-specific promoter (VTX-802(8)). Five-week-old PFIC2 female mice were injected with a single intravenous administration of VTX-802(8) at two different doses and followed until four months of age. Correct localization of BSEP in biliary canaliculi was observed in treated mice after sacrifice at either dose. Animals treated with the higher dose showed normalization of serum transaminase and bilirubin levels at three weeks post-injection. Moreover, these mice showed a partial but significant reversion of hepatomegaly, and the release of BS from the liver to bile and small intestine was significantly increased at 4- and 11-weeks post-injection, indicating that physiological bile secretion was partially restored. These early results indicate that VTX-802(8) has therapeutic potential for PFIC2. However, further development of the AAV vector and/or combination with other pharmacological products, might be investigated to enhance treatment efficacy and further revert the disease biomarkers. The development of a durable cure for PFIC2 and its translation to the clinic would provide a life-changing alternative for these pediatric patients with high unmet medical need.

658 Combination of CD4+ and CD8+ in HBV T-cell Therapy Enhances Virus Control by Increasing IFN-γ and TNF-α Secretion

Sven Schreiner, Sophia Schreiber, Ulrike Protzer, Eva Loffredo-Verde, Anna D. Kosinska

Institute of Virology, Technical University of Munich, Munich, Germany

As most therapies so far focus on $CD8^+$ cells, the role of $CD4^+$ T cell help in T-cell therapy has merely been investigated. T-cell based therapy is a promising means to treat chronic hepatitis B virus (HBV) infection and HBV-associated hepatocellular carcinoma. T cells engineered to express an HBV-specific T cell receptor (TCR) may cure an HBV infection upon adoptive transfer. We here investigate whether the addition of redirected $CD4^+$ T cells supports $CD8^+$ TCR-T cells. Recently generated MHC class I as well as MHC class II (MHC II)-restricted TCRs allowed to redirect T cells and eliminate HBV in cell culture. Both, $CD8^+$ and $CD4^+$ T cells, engrafted with HBV-specific TCRs secreted IFN-γ and TNF-α and killed HBV-positive target cells. Furthermore, the transfer of MHC I-restricted TCRs into a humanized mouse model infected with HBV caused a significant decline of virological markers with limited injury of the liver. In a next step, we investigated the therapeutic potential of MHC II-restricted HBV core-specific $CD4^+$ T cells and MHC I-restricted HBV surface-specific $CD8^+$ T cells alone and in combination in AAV-HBV-infected mice, modeling a chronic HBV infection upon restimulation with peptides Even if all groups could control HBV infection by lowering HBeAg and HBsAg, in the combination group, virological markers declined more pronounced by 2 to 3 logs. Better clearing of HBV antigens was accompanied by increased IFN-γ and TNF-α secretion by $CD4^+$ and $CD8^+$ T cells from the liver and spleen. Despite higher cytokine levels, the liver damage was kept to a minimum with alanine aminotransferase levels peaking between days 15 and 22 and normalizing again thereafter. Based on these data, we hypothesize a positive helper effect of $CD4^+$ T cells by stimulating $CD8^+$ cells and endogenous cytokine secretion.

659 *In Vivo* Screening Towards Hepatic Stellate Cell Targeting in Non-Alcoholic Steatohepatitis

Alex Araki, Martin Borch Jensen, Chris Carrico, Linda Chio, Atray Dixit, Ian Driver, Caroline Duwaerts, Daniel Fuentes, Vinay Kartha, Akela Kuwahara, Francisco LePort, Hikaru Miyazaki, Wyatt Morgan, Dimitry Popov, Smitha Shambhu, Chris Towne

Gordian Biotechnology, South San Francisco, CA

Non-alcoholic steatohepatitis (NASH) is a liver disease characterized by liver inflammation, fat buildup, and fibrosis modulated by a wide population of liver cell types such as hepatocytes and hepatic stellate cells. To effectively provide treatment to patients, it is important to specifically target cell-types with different interventions and tightly modulate expression of the transgene with a modality such as AAVs. Current AAV screening methods are unable to capture transgene expression at the single-cell level. Using single-cell RNA sequencing with expressed barcodes, we have developed a platform to give us transduction information in specific cell-types. Using this screening platform, we have been able to identify some cell-type specific AAV serotypes for liver-targeting and run head-to-head comparisons of regulatory elements to identify the best promoters for expression. We injected a pool of 17 serotypes, at a dose of 1E11 per serotype, into 3 mouse models to study fibrotic liver disease (n = 3 per model): carbon tetrachloride (CCl4), trans-fat containing amylin (AMLN) liver diet, and a non-diseased control. 2 and 4 weeks after AAV injection, we isolated and enriched for populations of transduced stellate cells and hepatocytes. These cell populations were sorted and ran through the 10x Genomics single-cell system. Subsequently RNA was sequenced using next-generation sequencing, and data was analyzed to find AAV serotypes that transduce specific cell-types. We find that several AAVs already validated in literature such as AAVrh10, AAVDJ8, AAVDJ9, and AAVDJ had high transduction in hepatocytes, higher than AAV8 that is actively used in liver clinical trials. From those screening results, we were able to identify several novel serotypes that are present in cholangiocytes and hepatic stellate cells. This screening platform was applied to 47 AAV transgene constructs of regulatory elements to increase transduction in hepatocytes in non-diseased and AMLN mice. Using this technology, we were able to identify a promoter in hepatocytes that had 2x RNA transcripts per cell higher than the albumin promoter. Using our screening platform, we were able to identify AAV serotypes with cell-type specificity and also measure their expression levels in disease relevant contexts. With this information, we have used our optimized AAV vector to screen therapeutic constructs in mice as well as large animal models, such as non-human primates.

661 Pigment Epithelium-Derived Factor (PEDF) Short Peptides Enhance the Proliferation of Articular Chondrocytes in Cell Culture, Induce Chondrocyte Trans-Differentiation of Mesenchymal Stem Cells and Promote the Regeneration of Damaged Cartilage in an Animal Model of Osteoarthritis

Yeou-Ping Tsao

Ophthalmology, Mackay Memorial Hospital, Taipei, Taiwan

Pigment epithelium-derived factor (PEDF) is shown to promote the expansion of corneal limbal stem cell and liver stem cell in cell culture. This make PEDF a potential tool in cell therapy. Here we report the effect of a PEDF short peptide (PSP) on the expansion of articular chondrocytes in cell culture. Primary chondrocytes were isolated from rat knee and cultivated in the presence of the PSP for 12 days. In this condition, chondrocytes not only grew faster, but also aggregated into huge three-dimensional colonies. In these colonies, PSP treatment markedly increased the numbers of aggrecan-positive cells, indicating the identity of chondrocytes. Moreover, PSP can promote chondrogenic differentiation of bone marrow-derived mesenchymal stem cells (BMSCs), as evident by the increased expression of chondrogenic marker genes and proteoglycans, as well as the phosphorylation of STAT3. Pharmacological inhibitors of PEDF receptor and STAT3 signaling dramatically blocked the effect of PSP on cultured MSCs. In addition, we investigated whether the PSP is able to induce cartilage regeneration in rat knees in which cartilage is already destroyed by monoacetate injection for 7 days. PSP was injected into knee joints twice, at 4-day intervals. When joint tissues were examined 10 days later, PSP induced extensive chondrocyte regeneration in the damaged cartilage, demonstrated by double immunostaining of BrdU to

track DNA synthesis and chondrocyte markers, including aggrecan, collagen type 2 and Sox9. In conclusion, PSP has the ability to promote cartilage regeneration, possibility through the expansion of remaining chondrocytes or the induction of trans-differentiation of BMSCs.

662 AUF1 Gene Therapy for Traumatic Skeletal Muscle Injury- Significantly Accelerated Muscle Regeneration in Preclinical Animal Models

Robert J. Schneider, Dounia Hanadi Abbadi, Riley McConnell, Beth Walters, Olga Katsara, Sophie Dornbaum, John Andrews

New York University School of Medicine, New York, NY

Traumatic skeletal muscle injuries are the most common debilitating injuries, whether in military service, sports, or accidents in everyday life. Traumatic muscle injury can become muscle wasting disease, with unproductive cycles of attempted muscle regeneration, exhaustion of muscle stem (satellite) cells, and continued degeneration and atrophy of the wounded muscle. Surgical repair of traumatic muscle injuries typically does little to improve muscle regeneration and quality of life. There are currently no FDA approved therapeutic interventions to promote muscle regeneration following traumatic muscle injury. There is, therefore, a large unmet need to develop therapeutic, approaches that significantly activate and restore satellite cells, promote successful muscle regeneration, reduce muscle atrophy and necrosis, and reduce the extensive time for muscle regeneration following traumatic injury. Following injury, muscle healing occurs in 3 phases over a period of 1 month in mice and 3-4 months in human: (1) Degeneration/necrosis, inflammation followed by its cessation; (2) Muscle regeneration, repair; and (3) Maturation and remodeling of muscle fibers (myofibers). All three processes, inhibition of inflammation and necrosis, regeneration and maturation of muscle need to be stimulated, which has not been currently achievable. AU-rich mRNA binding factor 1 (AUF1) is an RNA binding protein that binds repeated AU-rich elements (AREs) located in the 3' untranslated region of approximately 3% of mRNAs. ARE targets mRNAs for either rapid degradation, stabilization and/or increased translation, largely controlled by AUF1. We previously showed that in skeletal muscle, the majority of key regulators of satellite cell activation and maintenance, muscle regeneration, and mitochondrial biogenesis essential for muscle function, are encoded by ARE-mRNAs regulated by AUF1. Here, in preclinical animal models, we used supplementation of muscle AUF1 delivered to satellite and muscle cells by either systemic muscle specific AAV8-tMCK-AUF1 or lentivirus vector-AUF1 direct muscle administration gene therapy either during or prior muscle injury. We demonstrate following BaCl2 induced traumatic tibialis anterior (TA) muscle injury, that AUF1 gene therapy: (1) Reduces TA muscle atrophy, (2) Results in more rapid expression of satellite cell activation and myoblast differentiation markers including Pax7, MyoD and Myf5, while atrophic gene expression is strongly reduced as early as 3 days post-injury; (3) Increases expression of myozenins, indicators of myofiber maturity and muscle regeneration progression; (4) Rapidly reduces the expression of embryonic myosin Myh3, a marker of productive myogenesis; (5) Enhances the size of differentiated mature neo-synthesized myofibers, while reducing their percent, observable as early as 5-7 days post-injury; and (6) Dramatically reduces the time of post-injury muscle regeneration, including time for restoration of normal muscle histological morphology. Finally, genome-wide transcriptome and translatome analysis of C2C12 myoblasts cells expressing AUF1 from a lentivirus vector confirmed the pro-myogenic function of AUF1, which increases protein synthesis, induced upregulation of mRNAs that encode muscle contraction and regeneration pathways, and downregulation of mRNAs that encode inflammatory factors. These studies suggest that AUF1 overexpression accelerates muscle regeneration following traumatic injury and should be evaluated further as a candidate for human gene therapy.

663 Assessment of Therapeutical Potential and Advantage of a Dual AAV Approach for Duchenne Muscular Dystrophy

Sonia Albini, Laura Palmieri, Auriane Dubois, Nathalie Bourg, William Lostal, Isabelle Richard

GENETHON, Evry, France

Duchenne Muscular Dystrophy (DMD) is a severe rare pediatric disease that affects skeletal and cardiac muscles, leading to progressive muscle wasting and premature death. DMD is caused by X-linked mutations in the dystrophin gene that result in lack of dystrophin, a crucial protein required for the biomechanical support of muscle fibers and, as recently identified, for signaling function. Although DMD is a suitable disease for gene replacement therapy, the extent of Dystrophin transcript size exceeds by far the AAVs cargo capacity and only short versions of dystrophin (μDys) can be accommodated. Several forms of μDys are currently being investigated in clinical trials. However, while the therapeutic effects are unequivocally met in the animal models, results from clinical trials highlighted an insufficient correction of the disease and raised safety concerns due to the appearance of severe adverse events (AE) triggered by immunogenic reactions after vector delivery. This evidence supports the necessity to the identify strategies to face the challenges of safety and efficacy. It is still unclear to which extent microdystrophins can really replace the full-length dystrophin function in human patients. Our strategy is to generate a larger version of dystrophin (quasidystrophin-qDys EP2020/05837) including key additional structural and functional domains by a dual system based on homologous recombination of the overlapping region of two AAVs vectors. We first checked efficiency and safety parameters of our system by employing an innovative ddPCR-based methodology by which we proved that our Dual AAV approach, systemically administered in DBA2mdx mice, led to high transgene reconstitution efficiency and negligible ITRs-dependent concatemerization, and consequently to remarkable protein restoration in muscles. Our data indicated that mice treated systemically with Dual AAV-qDys displayed global improvement of muscle pathology and function. In particular, DBA2 mdx mice treated with qDys have lower fibrosis and higher muscle force and grip strength as compared to mice expressing similar amount of microdystrophin protein. The histological and functional amelioration was also associated with increased stability of the dystrophin-associated complex. Of note, no adverse effects were observed in these experiments. In conclusion, the efficiency of the system, by allowing the use of a safe dosing, supported the suitability of qDys for therapeutic investigation. The more performant gene candidate qDys together with the use of a new AAV capsid allowing a lowering of dose and preventing liver toxicity, has the potential to increase the correction of

the disease at higher level than the current uDys approaches, keeping in mind that supportive strategies might be needed to further improve first-generation gene therapies.

664 Preclinical Development of MyoDys45-55, a Gene Editing Therapy for Duchenne Muscular Dystrophy

William Dorst[1], Elizabeth Gibbs[1], Jonathan Nguyen[1], Jesus Perez[2], Laura Hagerty[1], Michael R. Emami[2], Niclas E. Bengtsson[3], Jeffrey S. Chamberlain[3], April D. Pyle[2], Melissa J. Spencer[2], Courtney S. Young[1]

Duchenne muscular dystrophy is a fatal muscle wasting disease typically caused by out-of-frame mutations in the *DMD* gene. Some therapeutic approaches for Duchenne aim to restore the reading frame and produce an internally deleted dystrophin protein similar to what occurs in the milder Becker muscular dystrophy. One way to achieve this reframing is with CRISPR/Cas9 gene editing. Gene editing offers the advantage of permanently changing the patient's own DNA and being able to retain more of the protein coding sequence than AAV-based gene replacement therapies. We have developed a gene editing therapy, MyoDys45-55, that generates an in-frame deletion of exons 45-55 and encompasses a hotspot of 50% of Duchenne patient mutations. We have demonstrated AAV delivery of MyoDys45-55 can restore dystrophin and function in a humanized mouse model of Duchenne. We have also tested this strategy in combination with immune suppression to dampen the immune response to AAV and Cas9. Here we describe preclinical studies assessing the efficacy, biodistribution, safety, and immune response to AAV-MyoDys45-55 in vivo. This work will advance development of this potential therapeutic for Duchenne that can permanently restore the reading frame for a large proportion of patients.

665 Smoking and Tetramer Tryptase Accelerate Intervertebral Disc Degeneration by Inducing METTL14-Mediated DIXDC1 m6 Modification

Ji Tu[1], Wentian Li[1], Philip Hansbro[2], Abhirup Das[1], Cao Yang[3], Jun Zou[4], Ashish Diwan[1]

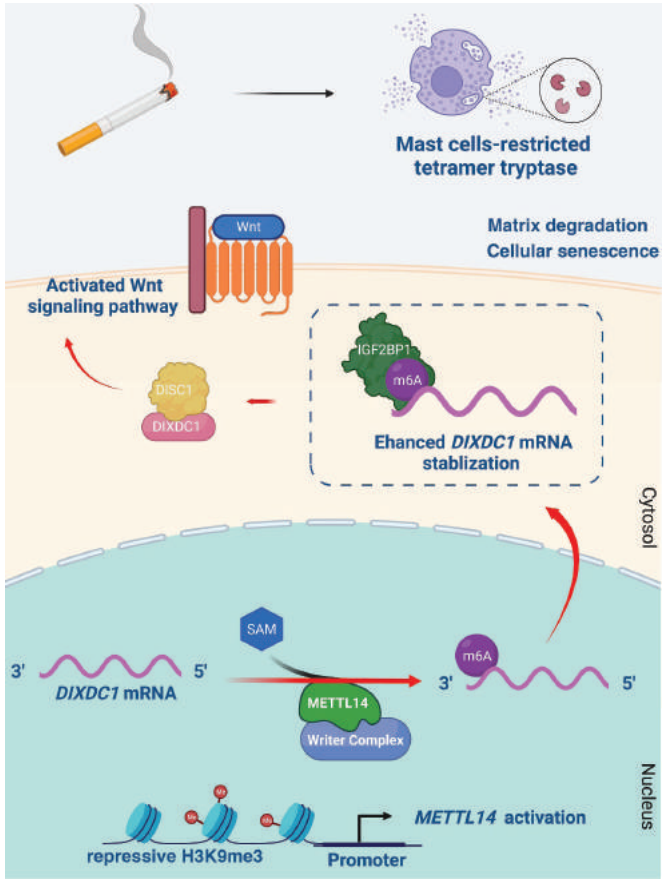
Although cigarette smoke (CS) and low back pain (LBP) are common worldwide, their correlations and the mechanisms of action remain unclear. We had shown that excessive activation of Mast Cells (MCs) and their proteases play key roles in CS associated diseases, like asthma, chronic obstructive pulmonary disease (COPD), blood coagulation and lung cancer. Previous studies also show that MCs and their proteases induce degenerative musculoskeletal disease. By using mice custom-designed smoke-exposure system, we demonstrated that CS results in intervertebral disc (IVDs) degeneration and the release of MC-restricted tetramer tryptases (TT) inside the IVDs. TT was found to regulate the expression of methyltransferase 14 (METTL14) at the epigenetic level by inducing N6-methyladenosine (m6A) deposition in the 3'-untranslated region (3'-UTR) of the transcript that encodes DIX Domain Containing 1 (*DIXDC1*). That reaction increases the mRNA stability and expression of *Dixdc1*. DIXDC1 functionally interacts with 'Disrupted in Schizophrenia-1' (DISC1) to accelerate the degeneration and senescence of nucleus pulposus (NP) cells by activating a canonical Wnt pathway. Our study demonstrates the association between CS, MC-derived TTs, and LBP. These findings raise the possibility that METTL14-medicated DIXDC1 m6A modification could serve as a potential therapeutic target to block the development of degeneration of the NP in LBP patients.



666 AAV.U7snRNA as a Platform to Deliver Antisense Sequences for mRNA Splicing Modification to Treat Neuromuscular Disorders

Nicolas Wein

Department of Pediatrics, Center for Gene Therapy - Nationwide Children's Hospital, Columbus, OH

Vectorized Exon skipping (VES) is a promising approach to treat neuromuscular disorders (e.g. Duchenne muscular dystrophy (DMD), Myotonic Dystrophy type (DM1)). It is based on restoring the reading frame of mRNA or interfere with toxic transcripts. Conventional approaches using antisense oligonucleotides (ASO) have several limitations such as the need of repeated injections due to their lack of stability and their limited tissue tropism into affected organs (e.g., heart and others). VES constructs packaged into AAV vectors are

able to overcome these limitations as the ASO is embedded into the sequence of a small nuclear RNA with its own promoter, thereby taking advantage of the continuous expression of AAV transgene cassettes and the better tissue access of AAVs over ASOs. This approach is currently being tested in a clinical trial for *DMD* exon 2 duplication (NCT04240314) and has been proven to be safe and well tolerated. Importantly, efficient exon skipping in muscle and increased levels of dystrophin protein were observed in all three treated patients. Based on these exciting results, we have developed additional VES vectors for new regions of the DMD gene: exon 44 and exons 6-8 multi-exon skipping. For the exon 44 program, several VES were tested *in vitro* in patient derived cells harboring different mutation surrounding or within exon 44. We also tested the most promising VES *in vivo* 3 months post intramuscular injection (IM) in a humanized mouse model carrying an exon 45 deletion (hDMD del45). In both models, around 85% of exon skipping was achieved, resulting in around 90% of truncated dystrophin expression. In hDMD del45, more than 50% force improvement and a significant reduction of inflammation were observed in the treated muscle. Minimal efficacious dose studies were also performed to determine the best AAV dose following systemic delivery. 3-month post-injection, similar results were obtained: efficient skipping, protein restoration and force improvement. We performed the same approach for exons 6-8 since we know based on literature that in canine models of DMD, skipping of exons 6-8 (CH2 domain) produce a highly functional dystrophin. Thus, skipping of exons 6-8 could be a promising treatment option for 4% of DMD patients. Exon skipping and dystrophin expression were evaluated *in vitro* using patient cell line harboring mutation with exons 6-8 and in our new humanized mouse model that contains a nonsense mutation in exon 7 (hDMD ex7ns). Both *in vitro* and *in vivo* data 3-months post IM data demonstrated that one of our VES could induced efficient exon skipping, resulting in around 50-70% of truncated dystrophin expression and significant increase in muscle eccentric force. To conclude, our lead candidates induce efficient *DMD* exon 44 or exons 6-8 skipping, resulting into dystrophin production and muscle strength improvement in major muscle groups affected in DMD. These two new AAV.U7snRNA skipping vectors represent promising gene therapy candidates for ~6-12% of DMD patients and will allow the production of nearly full-length, an advantage over micro-dystrophin approaches.

667 Precise Correction of Duchenne Muscular Dystrophy with Exon 51 Deletion by Adenine Base Editing-Induced Exon Skipping in a Humanized Mouse Model

Guoling Li[1], Jiajia Lin[2], Ming Jin[2], Zhifang Li[3], Qingquan Xiao[1], Linyu Shi[1], Ning Wang[2], Wanjin Chen[2], Chunlong Xu[3], Hui Yang[1,4]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[3]Lingang Laboratory, Shanghai, China,[4]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Duchenne muscular dystrophy (DMD) is the most common lethal, X-linked genetic muscle disease, caused by mutations in the *DMD* gene. While there are thousands of documented clinical mutations, nearly 60% of DMD-causing mutations occur in a "hotspot" region encompassing exons 43 to 55 of the *DMD* gene that encodes the central rod domain of dystrophin protein. Here, we target the correction of the *DMD* exon51 deletion mutation by exon-skipping therapy of the exon50 which may therapeutically benefit DMD patients. **Methods:** We generated a genetically humanized DMD murine model by replacing the mouse exon50 with human exon50, followed by the deletion of mouse exon51 ($DMD^{\Delta mE50,51,\ hE50KI}$), which disrupted the dystrophin open reading frames. Then, we explored the potential of using adenine base editor (ABE) to modify the splice donor sites of the *DMD* gene, causing skipping of a common *DMD* deletion mutation of exon51 by intramuscular injection and systemic delivery of AAV vectors. Then, we evaluated the extent of exon skipping, dystrophin restoration, and phenotypic improvements of cardiac and skeletal muscles 6 weeks after the treatment. **Results:** Humanized $DMD^{\Delta mE50,51,\ hE50KI}$ mice recapitulated many aspects of DMD pathological characterization, including the absence of dystrophin, inflammatory infiltration, muscle weakness, and creatine kinase (CK) release. Intramuscular injection of $DMD^{\Delta mE50,51,\ hE50KI}$ mice with AAV encoding ABE components as a split-intein trans-splicing system instituted >90% of the targeted exon-skipping in the DMD transcripts and restored up to 60% dystrophin *in vivo*. Furthermore, systemic delivery also efficiently restored dystrophin expression and ameliorated pathologic hallmarks of DMD, including histopathology, serum CK level and grip strength (Fig. 1). **Conclusions:** This unique DMD mouse model with the human genomic sequence allows *in vivo* assessment of clinically relevant CRISPR ABE gene-editing strategies as well as other therapeutic approaches and represents a significant step toward therapeutic translation of adenine base editing for correction of patients with DMD or other genetic neuromuscular diseases.

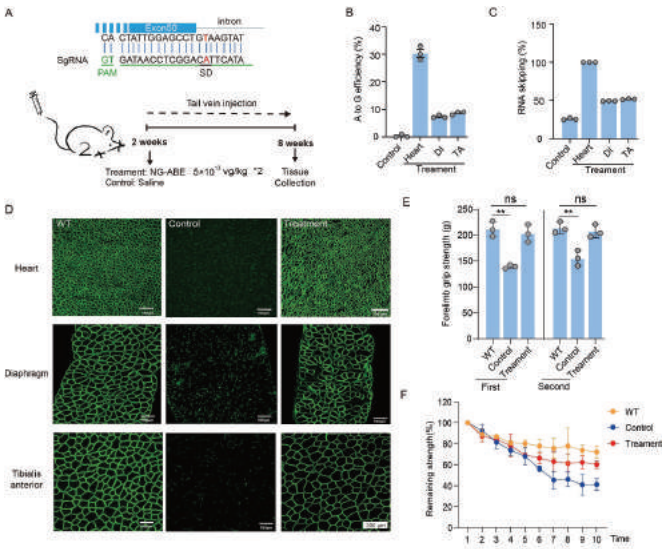

Figure 1. Intravenous delivery of NG-ABE system efficiently rescues dystrophin expression and muscle function in humanized DMD mice. A. Schematic of intravenous administration of NG-ABE particles and illustration of the human exon50 sgRNA binding position in SD. Sequence shows sgRNA (green line), target adenine (red) and PAM (green). Black arrows indicate time points for tissue collection after tail vein injection. Measurement by deep sequencing of splicing site mutation (B) and exon skipping (C) in tibialis anterior, diaphragm and heart after systemic delivery (n=3). D, Immunohistochemistry analysis shows restoration of dystrophin expression in the multi-muscle of DMD mice 6 weeks after injection. Dystrophin was shown in green. Scale bar, 200 μm. Forelimb grip strength (E) and remaining strength (F) were measured in WT, DMD mice, and DMD mice treated with NG-ABE particles (n=3). Data shown as mean ± SEM. Different asterisks represent statistical significance (P<0.01) in multiple comparison test using ANOVA.

668 Addition of a Protein Domain from the Dystrophin C-Terminus Improves Functional and Biochemical Properties of AAV-Encoded Microdystrophin

Steven Foltz[1], Randolph Qian[1], Chunping Qiao[1], Kirk W. Elliott[1], Ikram Hafiz[1], Jason Yang[1], George Dickson[2], Diogo Poroca[3], Pia Elustondo[3], Subha Karumuthil-Melethil[1], Joseph T. Bruder[1], Ye Liu[1], Olivier F. Danos[1]

Duchenne Muscular Dystrophy (DMD) is caused by mutations in the *DMD* gene, which encodes dystrophin, an essential component of the dystrophin-associated protein complex (DAPC) that forms a critical link between intracellular actin and extracellular laminin. The coding sequence for dystrophin is significantly larger than the packaging capacity for AAV, which has led to the development of engineered "microdystrophins" (μDys). These miniaturized dystrophin proteins rely on the modular structure of dystrophin, which contains several structurally homologous sections termed "spectrin-like repeats". Genotype analysis from patients with Becker Muscular Dystrophy, a milder allelic variant of DMD, indicates deletion of a number of these repeats may have a minimal impact on the protein function. However, the precise composition of dystrophin elements that should be retained within μDys to confer optimized functionality is still a matter of debate. The dystrophin C-Terminal (CT) region, which comprises 325 amino acids from the critical cysteine-rich domain to the carboxy-terminus, is a prominent example of this. Evidence suggests that the dystrophin CT region targets several proteins to the sarcolemma, including the signaling adapter syntrophin, and dystrobrevin which reportedly stabilizes DAPC in cardiac and skeletal muscle. This distal CT region has also been implicated in actin binding and dynamics with the DAPC. Early work with intramuscular administration of AAV.μDys showed improved muscle force with a μDys containing a longer CT region in *mdx* mice, a preclinical model of DMD. We have recently reported that systemically administered AAV.μDys with a longer CT region can facilitate recruitment of syntrophin and nNOS and may increase μDys protein stability; however, a functional comparison between μDys proteins with/without an extended CT region is lacking. To directly test whether the CT region contributes to μDys functionality we produced two vectors encoding versions of μDys under a muscle specific promoter without ("μDysCT48") or with ("μDysCT194") helix 1 of the coiled coil motif that includes binding sites for syntrophin and dystrobrevin. Vectors were administered via single intravenous injection into the tail vein at a dose of $5x10^{13}$ GC/kg in male *mdx* mice at 5 weeks of age. 12 weeks after dosing, forelimb muscle function was assayed by grip strength, followed by *in vitro* force measurements at necropsy. Both μDys increased body weight-normalized grip strength to near wild-type (WT) levels (μDysCT48 = 96.1%, μDysCT194 = 96.31%, compared to 85.83% for *mdx*). To more sensitively measure and compare muscle force effects produced by the two μDys, extensor digitorum longus (EDL) muscles were excised and subjected to *in vitro* force measurement followed by a protocol of repeated eccentric contractions. The μDysCT48 increased EDL specific force by 24.69% relative to *mdx* (to 62.83% of WT). In contrast, μDysCT194 led to significantly higher EDL force than μDysCT48 (51.92% increase over *mdx* μDysCT48, to 76.56% of WT). After 5 eccentric contractions, μDysCT194-treated EDLs produced 84.69% of initial force, which was significantly increased over *mdx* (78.21%), while μDysCT48-treated EDLs produced 81.62% of initial force (not significant vs. *mdx*). Altogether, our results suggest that an extended dystrophin CT region optimizes μDys functionality, thus warranting further development of μDysCT194 as a promising gene therapy candidate for DMD.

669 An AAV-shRNA DUX4-Based Therapy to Treat Facioscapulohumeral Muscular Dystrophy (FSHD)

Virginie Mariot, Eva Sidlauskaite, Laura Le Gall, Emilio Corbex, Julie Dumonceaux

UCL GOSH Institute of Child Health, London, United Kingdom

Facioscapulohumeral muscular dystrophy (FSHD) is one of the most common muscular dystrophies in adult and so far there is no curative or preventive treatment. FSHD is characterized by a loss of repressive epigenetic marks within the D4Z4 array located on the subtelomeric part of chromosome 4 , leading to chromatin relaxation and, when associated with a permissive chromosome 4, to the expression of the normally silenced DUX4 protein, whose open reading frame is present in each D4Z4 repeat. DUX4 is a transcription factor resulting in a poison protein through induction of downstream genes. Several pathways have been described as modulated by DUX4, ultimately leading to myofiber death. Here, we designed an AAV vector carrying a shRNA directed against DUX4 (AAV-shDUX4) to knock down DUX4 expression both in FSHD muscle cells and in the cre-inducible DUX4 bi-transgenic mouse model (ACTA1-MCM/FLExDUX4) that expresses high levels of DUX4 after tamoxifen injection. FSHD primary cells were transduced with a lentiviral vector containing the shDUX4. A downregulation of DUX4 mRNA was observed (up to 80%), showing the efficacy of the shRNA.

Next, ACTA1-MCM/FLExDUX4 mice were injected with either an AAV-shScrambled or an AAV-shDUX4 n the presence of tamoxifen. In the shDUX4-treated animals, a reduced activation of the genes downstream DUX4 (95% inhibition for Wfdc3, 88% for Ilvbl, 66% for Sord1), a reduced expression of the genes related to fibrosis (42% inhibition for Pdgfra, 66% for Col3a) and increased levels of myostatin (+80%) were observed at mRNA levels. The pathological signs of the disease were also decreased with a reduced number of re-generating fibres, less fibres with centrally located nuclei and a reduced inflammation. These results support an AAV-shDUX4 approach as a treatment for FSHD.

670 Systemic AAV9-*IGHMBP2* Gene Therapy Administration Ameliorates Disease Phenotype in Symptomatic Spinal Muscular Atrophy with Respiratory Distress Type 1 (SMARD1) Mice

Elisa Pagliari[1], Alessia Anastasia[2], Manuela Garbellini[2], Valentina Melzi[2], Floriana Bellandi[1], Michela Taiana[1], Giacomo P. Comi[1], Stefania P. Corti[1], Monica Nizzardo[2]

[1]Department of Pathophysiology and Transplantation, University of Milan, Milan, Italy,[2]IRCCS Foundation Ca' Granda Ospedale Maggiore Policlinico, Neurology Unit, Milan, Italy

Spinal Muscular Atrophy with Respiratory Distress type 1 (SMARD1) is a rare autosomal recessive motoneuron disease with infantile onset, with an estimated incidence of 1:100'000. It is caused by mutations in the *immunoglobulin mu-binding protein 2* (*IGHMBP2*) gene, which lead to a deficient amount of the encoded protein. The main clinical symptoms are distal muscular atrophy, diaphragmatic palsy and cardiac hypertrophy. Currently no therapies are approved. Recently, gene therapy emerged as a promising tool for monogenic disease as SMARD1. In our lab we already confirmed the efficacy of AAV9 vector therapy carrying the wild type copy of the *IGHMBP2* gene in SMARD1 mice model when administered pre-symptomatically at postnatal day 1 with both local or systemic injection. Our results participated to pave the way for the first Phase I/IIa gene therapy-based clinical trial for IGHMBP2-related disease started in December 2021 at Nationwide Children's Hospital, Columbus, Ohio. An important question in the field relates to the temporal requirements for this treatment. To examine the therapeutic window, in our work we tested the efficacy of a CAG-AAV9-*IGHMBP2* vector administered in already symptomatic SMARD1 mice. Expression analysis on treated mice demonstrated the ability of the construct in increase the IGHMBP2 protein expression level resulting in an extended survival time, and a partial improvement in phenotype and motor behaviours. No amelioration were observed in typical neuropathological hallmarks of the disease as motor neuron degeneration and muscular innervation even if an unexpected significative rescue of spinal cord astrocytosis and microglia overactivation were detected. In addition we demonstrated also a recovery of muscles fibers' diameter in gastrocnemius and a significative reduction of fibrosis in the heart. A parallel analysis of IGF1 axis involved in cardiac growth and contractility, already demonstrated altered in SMARD1, confirmed that our treatment was able to rescue this dysregulation. Overall, our results suggested that the delayed treatment was efficacious in partially rescue the pathological phenotype of symptomatic SMARD1 mice, leading us to speculate that the effects were more peripheral than acting at the central nervous system level, providing major benefits in the muscular compartment and in spinal cord neuroinflammatory microenvironment. These results support the possibility of a clinical translation of the treatment also during the symptomatic phase of the disease, and suggest the relevance of peripheral impairment in the progression of the pathology, opening future perspectives to the potentiality of a combined therapy targeting multi-organ defects.

671 A Novel Humanized Knock-In Mouse Modeling a Deep Intronic Mutation in Collagen VI-Related Dystrophy Has Weaker Grip Strength and More Centrally Nucleated Myofibers

Fady Guirguis[1], Lindsey Trank[1], Jun Cheng[2], Lisa Garrett[2], Véronique Bolduc[1], Carsten G. Bönnemann[1]

[1]Neuromuscular and Neurogenetic Disorders of Childhood Section, NINDS, NIH, Bethesda, MD,[2]Embryonic Stem Cell and Transgenic Mouse Core, NHGRI, NIH, Bethesda, MD

Collagen VI-related dystrophies (COL6-RDs) are a group of congenital and early-onset muscular dystrophies characterized by progressive muscle weakness and joint contractures leading to loss of ambulation. COL6-RDs are caused by deleterious variants in any of the genes (*COL6A1*, *COL6A2*, and *COL6A3*) that encode the 3 major α chains of collagen VI, a critical component of the myomatrix. A common recurrent dominant-negative deep intronic C>T variant in the *COL6A1* gene inserts a 72-nucleotide-long pseudoexon between exons 11 and 12 in 25% of the total *COL6A1* mRNAs in heterozygote cells. This variant causes the severe Ullrich congenital muscular dystrophy form of COL6-RDs. To study the pathomechanisms of this variant and to test splice-correction therapies *in vivo*, we have generated a humanized knock-in mouse model carrying the human *COL6A1* wild type (HumC) and/or mutant (HumT) alleles using CRISPR/Cas9. 25% of the *Col6a1* mRNAs transcribed by the *Col6a1*$^{HumT/HumT}$ mice contain the pseudoexon. Here, we characterized the functional and histological phenotypes of this new model and identified outcome measures that will enable assessing the efficacy of therapies in rescuing phenotype. Grip strengths and weights of male and female *Col6a1*$^{+/+}$, *Col6a1*$^{+/HumC}$, *Col6a1*$^{HumC/HumC}$, *Col6a1*$^{+/HumT}$, *Col6a1*$^{HumC/HumT}$, and *Col6a1*$^{HumT/HumT}$ mice were measured monthly from postnatal day (PND) 28 to PND 140 ($n \geq 4$). Additionally, the inverted screen test hanging times of *Col6a1*$^{HumC/HumC}$, *Col6a1*$^{HumC/HumT}$, and *Col6a1*$^{HumT/HumT}$ mice were measured at PND 56, 84, and 112. Muscles from 11-month-old *Col6a1*$^{+/+}$, *Col6a1*$^{+/HumC}$, and *Col6a1*$^{+/HumT}$ mice were stained for histological assessment. The grip strengths of *Col6a1*$^{HumC/HumT}$ and *Col6a1*$^{HumT/HumT}$ males were significantly weaker than *Col6a1*$^{+/+}$ and other HumC males at 1, 3, and 4-month-old ($p<0.05$). 3-5-month-old *Col6a1*$^{HumC/HumT}$ females were significantly weaker than *Col6a1*$^{+/+}$ and other HumC groups. *Col6a1*$^{HumT/HumT}$ females were significantly weaker than all non-HumT females at all tested ages. The weights of *Col6a1*$^{HumC/HumT}$ males were significantly lower than *Col6a1*$^{HumC/HumC}$ at 2 months and lower than *Col6a1*$^{+/HumC}$ males at 2 and 3 months. There was no significant difference between the weights of all other genotypes. The hanging times of *Col6a1*$^{HumC/HumT}$ males were significantly

shorter than those of *Col6a1*$^{HumC/HumC}$ at 2 and 3 months of age. The hanging times of 3 and 4-month-old *Col6a1*$^{HumC/HumT}$ females were significantly shorter than *Col6a1*$^{HumC/HumC}$ females. The differences between the hanging times of all other groups were not statistically significant. Our preliminary histological data indicate that the quadriceps of *Col6a1*$^{+/HumT}$ mice had more internalized nuclei than the other genotypes' quadriceps. Furthermore, the tibialis anterior and quadriceps muscles of *Col6a1*$^{+/HumT}$ mice had more internalized nuclei than the extensor digitorum longus, gastrocnemius, soleus, and triceps muscles. Our findings show that central nuclei quantification and grip strength measurement of this mouse model could be appropriate phenotypic outcome measures to assess splice-correction therapies. The generation of humanized mouse models is an effective tool for the preclinical study of splice-modulating therapeutics directed at human disease-causing variants.

672 Developing Cas13-ADAR-Mediated *DUX4* mRNA Editing as a Prospective Therapy for FSHD

Noushin Saljoughian[1], Genesis Snyder[1], Lara Rizzotto[2], Colin Maguire[1], Yasemin Sezgin[1], Lindsay M. Wallace[3], Meisam Naeimi Kararoudi[1], Dario Palmieri[2], Scott Q. Harper[3]

[1]Center for Childhood Cancer, CRISPR/Gene editing core, Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH,[2]Department of Cancer Biology and Genetics, Gene Editing Shared Resource, The Ohio State University, Columbus, OH,[3]Center for Gene Therapy, Abigail Wexner Research Institute, Nationwide Children's Hospital, Columbus, OH

Facioscapulohumeral Muscular Dystrophy (FSHD) is among the most prevalent muscular dystrophies, affecting over 830,000 people worldwide. FSHD is an autosomal dominant or digenic disorder caused by de-repression of the toxic *DUX4* gene in skeletal muscle. DUX4 encodes a transcription factor that is normally active during embryogenesis but otherwise off in skeletal muscle. Currently no treatment exists that alters the course of FSHD, and therapy development remains an unmet need in the field. We propose that the most direct route to FSHD therapy will involve *DUX4* inhibition. Numerous labs in the FSHD field, including ours, are developing various strategies to inhibit *DUX4* using different mechanisms. Here we describe an approach to silence *DUX4* mRNA using new CRISPR/Cas13-based RNA editing strategy. Cas13 was originally developed as a RNA-guided CRISPR enzyme that cleaves RNA and not DNA. In addition, modified Cas13 can also be employed to precisely edit single bases on mRNAs. To do this, Cas13 is fused to a modified ADAR2 sequence (Adenosine Deaminase Acting on RNA) to produce a fusion protein that can direct cytidine-to-uridine editing on target mRNAs (C-to-U). Using this approach, glutamine and arginine codons can be edited to stop codons, thereby producing truncated, potentially non-toxic *DUX4* open reading frames. This precision editing requires the use of guide RNAs. Because this technology is new, guide RNA design still requires optimization. Here we developed a high-throughput dual reporter system to test Cas13/ADAR-mediated RNA editing of *DUX4* mRNAs. Our strategy involved developing complex stable cell lines expressing doxycycline-inducible Cas13/ADAR; a transcriptionally active but non-toxic *DUX4* ORF; and NanoLuciferase reporter gene driven by a DUX4-induced promoter. Thus, NanoLuc is expressed in the presence of DUX4 and reduced or absent with DUX4 knockdown treatments. We designed 117 different guide RNAs targeting 34 *DUX4* glutamine and 5 arginine codons, with the goal of editing premature STOP codons. To date, we have identified several DUX4-modifying gRNAs that caused significantly reduced NanoLuc expression, suggesting successful editing of *DUX4* mRNA. Our results may provide another treatment option for FSHD, and has implications for using this system to edit other transcripts. We will discuss prospects for uncovering better "rules" for designing effective RNA-editing gRNAs.

673 Antibody-Mediated Delivery of AAV9 Enhances Skeletal Muscle Targeting and Therapeutic Efficacy in Mouse Models of Genetic Muscle Disease

Michael Stec, David Golann, Valerie Le Rouzic, Daniel Gomez, Lawrence Miloscio, Naveen Khan, Anna Camilleri, Evangelos Pefanis, Sven H. Moller-Tank, Leah Sabin, Christos Kyratsous, Mark Sleeman

Regeneron Pharmaceuticals, Tarrytown, NY

The use of adeno-associated virus (AAV) for the delivery of gene therapies holds great promise for the treatment of many muscle diseases, with recent clinical trials demonstrating improved muscle function following systemic AAV treatment. However, the extremely high systemic doses needed to deliver AAV to all skeletal muscles throughout the body often results in off-target tissue transduction (e.g., liver) and toxicity, with only low amounts of AAV effectively transducing muscle. To overcome this challenge, we have taken a rational engineering approach to design AAVs that are targeted to skeletal muscle via the conjugation of muscle-specific antibodies (Abs). We generated and screened Abs against the skeletal muscle-specific protein, CACNG1, and conjugated these Abs to AAV9 capsids with mutated galactose binding domains. We then packaged therapeutic transgene constructs into these muscle-retargeted capsids, and tested their efficacy in mouse models of disease, including: Duchenne muscular dystrophy (D2-mdx), X-linked myotubular myopathy (MTM1 KO) and limb-girdle muscular dystrophy 2I/R9 (Fkrp^{P448L}). Overall, systemic treatment of diseased mice with our CACNG1 Ab-retargeted AAV9 substantially enhanced therapeutic transgene expression within multiple skeletal muscles while also reducing transduction of the liver when compared to WT AAV9. In D2-mdx mice, higher expression of microdystrophin in the muscle of CACNG1 Ab-retargeted AAV9 treated mice lead to greater reductions in muscle damage (assessed by serum creatine kinase) and improved grip strength compared to WT AAV9 treated mice. In MTM1 KO mice, higher expression of MTM1 in the muscle of CACNG1 Ab-retargeted AAV9 treated mice led to improved muscle histopathology and enhanced survival compared to AAV9 treated mice. Finally, in Fkrp^{P448L} mice, higher expression of FKRP in the muscle of CACNG1 Ab-retargeted AAV9 treated mice led to enhanced glycosylation of α-dystroglycan and improved exercise capacity. Importantly, the functional improvements observed in these studies were achieved using relatively low systemic doses of CACNG1 Ab-retargeted AAV9 (ranging from ~2E+12vg/kg to ~6E+13vg/kg), and compared to WT AAV9, there was a ~95% reduction in transgene expression in the

livers of CACNG1 Ab-retargeted AAV9 treated mice. Additionally, while our CACNG1 Ab-retargeted AAV9 platform was developed to enhance skeletal muscle transduction, we found that by modulating the galactose binding mutations in our capsid, we can skew tropism towards both skeletal muscle and heart, which is beneficial for certain diseases such as Duchenne muscular dystrophy. In summary, these studies have demonstrated that CACNG1 Ab-mediated delivery of AAV9 may be used to enhance the therapeutic efficacy and reduce off-target toxicity of gene therapies in multiple muscle diseases.

674 Sustained Efficacy of CRISPR-Cas13b Gene Therapy for FSHD is Challenged by Immune Response to AAV.Cas13b Vectors

Scott Q. Harper[1,2], Gerald Coulis[3], Noah Taylor[1], Gholamhossein Amini Chermahini[1], Allison Fowler[1], Armando Villalta[3], Oliver King[4], Afrooz Rashnonejad[1,2]

[1]Center for Gene Therapy, The Abigale Wexner Research Institute of Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH,[3]Department of Physiology and Biophysics, Institute for Immunology, University of California at Irvine, Irvine, CA,[4]Department of Neurology, The University of Massachusetts Chan Medical School, Worcester, MA

Facioscapulohumeral muscular dystrophy (FSHD) is potentially devastating muscle disease caused by de-repression of the toxic *DUX4* gene in skeletal muscle. FSHD patients may benefit from *DUX4* inhibition therapies, and although several experimental strategies to reduce *DUX4* levels in skeletal muscle are being developed, no approved disease-modifying therapies currently exist. We developed a CRISPR-Cas13b system that cleaves and eliminates *DUX4* mRNA and protein, protects cells from DUX4-mediated death, and reduces FSHD-associated biomarkers *in vitro*. We found little to no evidence of collateral transcript cleavage or significant off-target effects in human myoblasts *in vitro*. *In vivo* delivery of the CRISPR-Cas13b system with adeno-associated viral vectors (AAV6) reduced acute damage caused by high *DUX4* levels in a mouse model of severe FSHD. However, protection was not sustained over time, with reductions in Cas13b and guide RNA levels between 8 weeks and 6 months after injection. In addition, wild-type mice injected with AAV.Cas13b showed muscle inflammation with infiltrates containing AAV.Cas13b-responsive CD8+ CD4+ cytotoxic T cells. Our findings suggest successful *in vivo* implementation of CRISPR/Cas13-based gene therapies may require strategies to mitigate immune responses.

675 iTenocytes on Microgrooved Scaffolds Promotes Achilles Tendon Regeneration

Giselle Kaneda[1], Julie Chan[1], Chloe Castaneda[1], Angela Papalamprou[1], Julia Sheyn[1], Oksana Shelest[1], Dave Huang[1], Nadine Kluser[2], Victoria Yu[1], Gian Ignacio[1], Arkadiusz Gertych[1], Ryu Yoshida[1], Melodie Metzger[1], Wafa Tawackoli[1], Andrea Vernengo[1], Dmitriy Sheyn[1]

[1]Cedars-Sinai Medical Center, Los Angeles, CA,[2]AO Research Institute Davos, Davos, Switzerland

50% of musculoskeletal injuries involved tendons and ligaments, which have a poor innate healing capacity. Full structure and function restoration after injury remains a major unmet clinical need. Developing a tissue engineered tendon could dramatically alter patient outcomes, yet current methods fall short in terms of biomechanical performance and organization. Previously, we have shown the tenogenic potential of iPSC-derived mesenchymal stromal cells (iMSCs), stimulated by scleraxis (SCX) overexpression (iMSC^{SCX+}). We have developed a 3D-printed polycaprolactone (PCL) scaffold (Fig. 1a) with uniaxial microgrooves that induces end-to-end cellular alignment, mimicking cues found in developing tendons. The goal of this study was to explore the potential of iMSC^{SCX+} seeded onto 3D printed microgrooved PCL scaffolds to improve tendon regeneration in a rat model of Achilles tendon defect repair. Non-patterned scaffolds (NPS) and microgrooved scaffolds (MS) were 3D printed through microgrooved and non-patterned nozzles. Scaffolds were imaged using SEM and tested for printing consistency and biomechanical properties. Human iPSCs were differentiated to MSC lineage using our published protocol (iMSCs) and lentivirally transduced with SCX-GFP. NPS and MS were seeded with iMSC^{SCX+} and cultured to assess cell alignment and gene expression. iMSC^{SCX+} seeded MS were tested in a rat model of Achilles tendon defect with the following groups: 1) Suture only, 2) MS only, and 3) MS+iMSC^{SCX+}. An Achilles defect was surgically induced and either sutured or repaired with MS only or with iMSC^{SCX+} seeded MS (Fig. 2a). For follow-up, gait analysis was performed. At 6 weeks post-surgery, the tendons were harvested for biomechanical testing and histological and immunofluorescent (IF) staining. SEM image analysis (Fig. 1e) showed consistency in scaffold filament size from 3D printing (Fig. 1b). Biomechanical testing of the scaffolds showed that MS had biomechanical properties comparable to native tendon (Fig. 1c). Gene expression analysis of iMSC^{SCX+} seeded on MS or NPS *in vitro* revealed a significant upregulation of tendon marker expression in the iMSC^{SCX+} grown on MS compared to 2D culture or NPS (Fig. 1d). These results were further validated by IF with cells appearing more linearly organized on the MS compared to the NPS (Fig. 1e and 1f). *In vivo,* gait analysis found that the MS+iMSC^{SCX+} group had significant improvements in functional gait recovery compared to the control groups (Fig. 2a). Biomechanical testing of the tendons showed a significant improvement in biomechanical properties in the MS+iMSC^{SCX+} group compared to that of the Suture and MS only groups (Fig. 2b). Regular tissue formation in MS+iMSC^{SCX+} group seemed to be observed in histology (Fig. 2b) and IF stainings (Fig. 2c). This study shows the potential of iMSC^{SCX+}-seeded microgrooved scaffolds as a viable alternative for current tendon defect treatments.

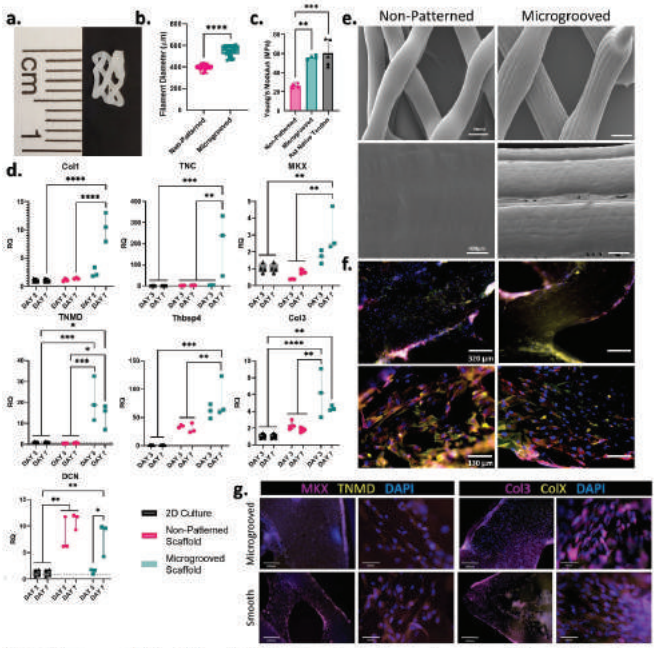

Fig 1: Microgrooved 3D printed scaffolds has biomechanical properties comparable to native tendon and increases tenogenic expression in iMSC^{SCX+}. (a) Scaffold macro-topography. (b) Filament diameter. (c) Scaffold vs native tendon elasticity. (d) Scaffold gene expression. (e) SEM images of non-patterned and microgrooved scaffold. (f) Cellular alignment imaging. (g) ICC staining of scaffold at 4x and 20x.

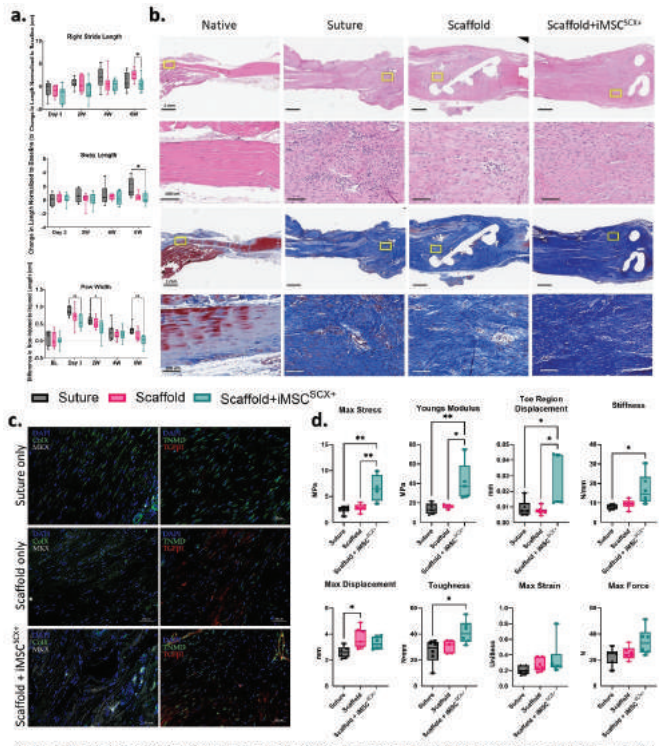

***Fig 2*: iTenocytes-seeded microgrooved scaffolds to regenerate Achilles tendon defect in rats.** *(a) Gait analysis. (b) H&E (top) and Massons Trichome staining (bottom) of Achilles tendon. (c) IF staining of Achilles tendon. (d) Biomechanical testing results.*

676 Investigation of Mortalin's Role in Aberrant Scar Formation Using Human Dermal Fibroblasts and Rat Incisional Scar Model

Chae-Ok Yun[1,2], Hyo Min Ahn[3]

[1]Gene-Medicine, Seoul, Korea, Republic of,[2]Hanyang University, Seoul, Korea, Republic of,[3]GeneMedicine, Seoul, Korea, Republic of

Wound healing is a complex multistep process, and dysregulation of this process causes formation of pathologic scars. In present report, we investigated the role of chaperone protein, mortalin, in scar formation and its interaction with interleukin-1α receptor using in vitro and in vivo scar formation models. A recombinant adenovirus expressing short hairpin RNA against mortalin (dE1-RGD/GFP/shMot) was generated and its effect on dermal fibroblasts were evaluated by assessment of cell viability, qRT-PCR, western blotting, immunofluorescence, and immunoprecipitation studies. An incisional wound model using rats were utilized to evaluate the effect of dE1-RGD/GFP/shMot on scar formation. *In vitro*, the mortalin-treated human dermal fibroblast displayed a significant increase in proliferation of type I collagen, α-smooth muscle actin, transforming growth factor-β, phospho-Smad2/3-complex, and NF-κB expression levels. Further, immunofluorescence staining revealed markedly increased mortalin and interleukin-1α receptor protein in keloid tissues compared to those of nonpathological normal tissues, demonstrating that mortalin and interleukin-1α receptor were responsible for the aberrant fibrosis of keloid tissues. *In vivo*, dE1-RGD/GFP/shMot treatment significantly decreased the scar size and type-I-collagen, α-SMA, and phospho-Smad2/3-complex expression levels in rat incisional scar tissues. Together, our findings demonstrate that mortalin and interleukin-1α contribute to aberrant fibrosis during wound healing process, and suppression of mortalin expression level by dE1-RGD/GEP/shMot can effectively inhibit the TGF-β/α-SMA axis and NF-κB signal pathways to prevent aberrant fibrosis during scar formation.

677 Use of Circular RNA Guides to Correct a Hotspot of Dominant-Negative Glycine Substitutions Causing Collagen VI-Related Dystrophies

Astrid Brull, Veronique Bolduc, Carsten G. Bonnemann

NINDS/NIH, Bethesda, MD

Collagen VI-related dystrophies (COL6-RD) are a group of congenital neuromuscular disorders for which there is no effective treatment. Dominant-negatively acting pathogenic variants, in particular glycine substitutions of the conserved collagenous Gly-X-Y motives, are common in the triple helical domains of the *COL6A1*, *COL6A2* and *COL6A3* genes. By virtue of their specific position in the triple helical domain they are capable of incorporating into the hierarchical assembly of the collagen α1, α2 and α3 (VI) chains and as a consequence, produce a dysfunctional collagen VI extracellular matrix. Two of the most common Gly substitutions, p.G284R and p.G293R are located in the alpha1(VI) chain, in a region that constitutes a hotspot for dominant-negative mutations. Most of glycine missense pathogenic variants are caused by a single guanosine (G) to adenosine (A) change, making them suitable for the use of an RNA editing approach using endogenous adenosine deaminases (ADARs). ADARs use double-stranded RNAs as a substrate to catalyze adenosine (A)-to-inosine (I), which mimics

G during translation. Here, we investigate the use of circular ADAR-recruiting RNAs to recruit endogenous ADAR enzymes to change a specific A to I, as a therapeutic approach for collagen VI-related dystrophies caused by G>A changes. RNA circularization improves RNA stability and increases resistance to cellular exonucleases, improving the efficiency and durability of programmable RNA editing. Strikingly, preliminary results in HEK293T cells with fluorescence reporters for both the p.G284R and p.G293R alleles showed percentages of RNA editing up to 22% and 25%, respectively, using a single circular ADAR-recruiting RNA to address both variants. This approach will be tested *in-vitro* in patient-derived fibroblasts and *in-vivo* in humanized mouse models we are generating.

678 Nuclease-Dead Cas9-Mediated Downregulation of alpha-Synuclein as a Disease-Modulatory Therapeutic Strategy for Parkinson's Disease

Birgitt Schuele[1], C. Alejandra Morato Torres[1], Faria Zafar[1], De'Angelo Hermesky[1], Jocelyn Palafox Vazquez[1], Desiree Piper[2], Danuta Sastre[3], Lei Stanley Qi[4], Laurie Sanders[5], Deniz Kirik[6]

[1]Pathology, Stanford Medicine, Stanford, CA,[2]Department of Biological Sciences, San Jose State University, San Jose, CA,[3]Biosciences Division, SRI International, Menlo Park, CA,[4]Bioengineering, Chemical & Systems Biology, Stanford University, Stanford, CA,[5]Neurology and Pathology, Duke Clinical Research Institute, Durham, NC,[6]Lund University, Lund, Sweden

Parkinson's disease and related alpha-synucleinopathies show growing numbers due to an aging society. However, no approved disease modulatory therapies exist that halt disease progression. Alpha-synuclein is a critical therapeutic target that is found as an aggregated form in Lewy bodies, the diagnostic hallmark of Parkinson's disease, and mere overexpression of alpha-synuclein in hereditary conditions leads to neurodegeneration. Here, we describe the development of a nuclease-dead S. aureus Cas9 (sadCas9) CRISPR interference (CRISPRi) system to downregulate alpha-synuclein in 1) a human induced pluripotent stem cell (iPSC)-derived neuronal model and 2) a transgenic humanized alpha-synuclein mouse model. The mechanism of action is based on the principle that a complementary single guide RNA (sgRNA) recruits sadCas9 mutant protein to the promoter region of alpha-synuclein and inhibits transcription resulting in reduced target gene expression. We want to test whether this approach has the potential to become a therapeutic strategy for disease modification in Parkinson's disease. We designed and screened 32 sgRNAs across the human *SNCA* promoter and identified several sgRNAs that mediate the downregulation of alpha-synuclein at varying levels in HEK cells and human iPSC models. CRISPRi downregulation of alpha-synuclein in patient iPSC-derived neuronal cultures showed reduced oxidative stress levels and mitochondrial DNA damage. Next, we tested a lead sgRNA in a humanized alpha-synuclein mouse using an all-in-one AAV9 construct from which we expressed sadCas9 and the lead sgRNA. Four months old mice were stereotactically injected with the AAV9 lead or control sgRNA and euthanized 1 or 6 months after surgery. We show robust expression of sadCas9 and reduction of alpha-synuclein (mRNA and protein) after unilateral stereotactic injection into the substantia nigra of adult mice. Initial microglia activation after one month subsided, and microglia marker Iba1 and CD16/32 did not significantly differ at six months between lead sgRNA and control conditions. We conclude that Cas9 interference technology facilitates alpha-synuclein mRNA and protein reduction in *vitro* and *in vivo*. This pre-clinical work shows promise in advancing to a regenerative medicine-based therapeutic genetic therapy for Parkinson's disease or related alpha-synucleinopathies.

679 Gene Therapy Using a CNS Dominant Human FMRP Isoform Rescues Seizures, Fear Conditioning, and Sleep Abnormalities in Fmr1 KO Mice

Hayes Wong[1], Alex Hooper[1], Hye Ri Kang[2], Shiron J. Lee[1], Jiayi Zhao[1], Chanchal Sadhu[3], Satinder Rawat[3], Steven J. Gray[2], David R. Hampson[1]

[1]Leslie Dan Faculty of Pharmacy, University of Toronto, Toronto, ON, Canada,[2]Department of Pediatrics, University of Texas Southwest Medical Center, Dallas, TX,[3]Taysha Gene Therapies Inc., Dallas, TX

Fragile X Syndrome (FXS) is a monogenic neurodevelopmental disorder caused by the loss of expression of the fragile X mental retardation protein (FMRP), a key mRNA binding protein required for brain function. FXS is the most prevalent single gene cause of autism and intellectual disability in males, affecting approximately 1:5000 men and 1:8000 women. Viral vector-mediated gene replacement therapy has been studied in the past as a potential viable treatment for the disorder. Although partial rescue of abnormal behaviors has been reported in Fmr1 KO mice and rats, complete rescue of the abnormal phenotypes has not been achieved, including certain salient features such as audiogenic seizures in Fmr1 KO mice. Here, the distribution pattern, therapeutic effects, and safety profile of a novel self-complementary adeno-associated viral (AAV) vector containing a major human brain isoform of FMRP were studied following intrathecal injection into neonatal wild-type and Fragile X KO mice at a clinically relevant dose. Widespread FMRP expression was observed throughout the brain at 1, 3 and 6 months after injection in AAV-treated KO mice. Expression was primarily in neurons with sparse expression in glia, similar to the endogenous expression profile in uninjected WT mice. In behavioral tests, AAV-treated KO mice showed robust suppression of audiogenic seizures and normalization of fear conditioning behavior. Multi-day monitoring of circadian locomotor activity revealed normalization of hyperactivity and sleep, while electroencephalographic recordings showed reversal of slow wave deficits. Further assessment of individual transgene expression and behavioral responses demonstrated correlations between the level of FMRP expression and drug efficacy. No significant adverse effects were observed in behavioral, serological or pathohistological markers up to 12 months after intrathecal injection into WT adult mice. These preclinical findings represent our most comprehensive assessment of AAV-mediated gene therapy in Fmr1 KO mice to date and further demonstrate the validity of its use for treating the most common genetic cause of cognitive impairment and autism in children.

680 AAVrh10 Mediated Gene Replacement Therapy Targeted to Schwann Cells to Treat CMT1X Demyelinating Neuropathy

Alexia Kagiava, Melina Christou, Irene Sargiannidou, Kleopas A. Kleopa

The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus

Introduction In previous work we demonstrated the efficacy of two different AAV serotypes, AAV9 and AAVrh10, to target the peripheral nervous system (PNS) and to transduce myelinating Schwann cells for the treatment of demyelinating neuropathies. X-linked Charcot Marie-Tooth disease type 1 (CMT1X) is the second most common form of CMT neuropathies resulting from loss of function mutations in the *GJB1* gene, which encodes the gap junction protein connexin 32 (Cx32). Cx32 is highly expressed in myelinating Schwann cells throughout the PNS forming gap junctions in non-compact myelin areas. To develop a gene replacement therapy for CMT1X, we performed a dose-response treatment trial using the AAVrh10 serotype to deliver the human *GJB1* gene into the *Gjb1*-null mouse model of CMT1X, under the control of the Schwann cell specific human myelin protein zero (MPZ) promoter. **Methods** AAVrh10-*MPZ.Egfp* (mock) and AAVrh10-*MPZ.GJB1* (therapeutic) vectors were delivered by lumbar intrathecal injection in wild type or *Gjb1*-null mice, respectively. The mock vector was tested at the dose of $2x10^{11}$ vg for biodistribution and EGFP expression, while the therapeutic vector was tested in three different doses ($1x10^{11}$, $2x10^{11}$, and $1x10^{12}$ vg) in order to evaluate biodistribution and Cx32 expression in PNS tissues. We then proceeded with a dose-escalation treatment trial in 2-month-old *Gjb1*-null mice and evaluated functional and morphological outcomes compared to mock-vector treated littermates. Functional analysis included behavioral testing at 2- and 4-months post-injection while electrophysiological and morphological analysis was conducted 4 months post-injection. **Results** Biodistribution and expression analysis of the mock vector showed widespread targeting of the PNS with vector genome copy numbers (VGCNs) reaching 3.3±0.79 in lumbar roots, 2.7±1.38 in proximal sciatic nerves and 0.1±0.02 in the distal parts of the sciatic nerve. EGFP expression rates reached 24.0±1.64 % in lumbar roots and 49.5±4.54 % in sciatic nerves. Biodistribution and expression analysis of the therapeutic vector showed a dose-dependent Schwann cell transduction with most efficient targeting of peripheral nerves in mid- and high-dose treated *Gjb1*-null mice. Cx32 expression rates in PNS Schwann cells of low-dose treated mice ranged between 23.5-30.7%, whereas they were significantly higher in PNS tissues of mid- and high dose treated animals, ranging between 72.1 and 82.6%. Functional outcomes showed improved grip strength and sciatic nerve motor conduction velocity in animals injected with the standard and high vector dose, but not with the low dose. Furthermore, in both anterior lumbar roots and peripheral nerves, we observed a statistically significant reduction of around 50% in morphological parameters evaluated including the ratio of abnormally myelinated fibers and the number foamy macrophages, in all three treatment groups (low, standard and high-dose AAVrh10-*hMpz-GJB1* groups) compared to the mock-treated controls. **Conclusion** This study demonstrates that a single lumbar intrathecal injection of clinically relevant doses of AAVrh10-*MPZ.GJB1* vector leads to adequate biodistribution to the PNS and high rates of Schwann cell-specific therapeutic gene expression, as well as significant therapeutic benefit evaluated by functional and morphological outcomes in the model of CMT1X demyelinating neuropathy.

681 Identifying Potential Clinical Outcomes for Future Clinical Trials for SLC13A5 Deficiency

Sydney Cooper[1], Kim Nye[2], Tanya Brown[2], Souad Messahel[1], Kimberly Goodspeed[1]

[1]UT Southwestern Medical Center, Dallas, TX,[2]TESS Research Foundation, Menlo Park, CA

Cellular metabolism is a complex process required for organisms to maintain life. Disruptions to citrate transport caused by biallelic loss of function variants in the *SLC13A5* gene leads to a rare genetic neurodevelopmental disorder called SLC13A5 deficiency (i.e. SLC13A5 Epilepsy, Citrate Transporter Disorder, Developmental Epileptic Encephalopathy-25). Gene therapy presents an opportunity to target the root cause of monogenic disorders such as SLC13A5 deficiency, and there is an AAV9-based gene therapy for this in preclinical development. Patients present with infantile epilepsy, severe motor impairments, limited language abilities, disruptive sleep problems, and teeth hypoplasia. Individuals typically present with seizures within the first few days of life, often have recurrent episodes of status epilepticus, and have severe developmental disability requiring lifelong dependence on caregivers. Treatment is currently limited to supportive care to manage seizures and other disease manifestations, and there is an unmet need to address the developmental aspects of the disorder. It is important to establish a disease concept model that characterizes the disease burden and most significant challenges. Caregiver perspective contributes to improved disease understanding and the identification of clinical outcomes that are meaningful for the affected individual and their caregivers. We conducted a cross-sectional survey of SLC13A5 deficiency caregivers with both Likert scale and free responses. Surveys were distributed to English-speaking families through the TESS Research Foundation caregiver network. Since this is an inherited disorder that was discovered in 2014, several caregivers have 2 or 3 affected children. Twenty-five caregivers submitted a total of 27 responses that each represent a unique affected child. The objectives of this qualitative and quantitative survey were to define the goals and concerns of the caregivers, and to describe the experience of caring for an individual with SLC13A5 deficiency. The symptoms identified as severely impactful by the caregivers were speech impairments (70.4%), motor disability (63.0%), cognitive impairments (48.1%), and seizures (48.1%). Differences in how SLC13A5 deficiency affects patients and caregivers were apparent between patient age groups. Caregivers of individuals younger than 7 years reported seizures and motor disability as major concerns, while those with older dependents focused more on developmental disability that limited their independence. Meaningful clinical outcomes identified include the affected individual gaining the ability to walk, dress, toilet, eat, speak, or read, as well as reductions in seizure frequency and severity for those with uncontrolled seizures. SLC13A5 deficiency is a primary epilepsy, yet there are other aspects of this disease that are important to patients and their families. In addition to seizure control, success for a gene therapy for SLC13A5 deficiency would demonstrate improvements in mobility, cognition,

and communication. Future clinical trials for this disorder should consider outcome measures that capture these symptoms. This study demonstrated that families of people affected by SLC13A5 deficiency value a broad spectrum of clinical outcomes, demonstrating the importance of including their perspective in therapeutic development.

682 Engineered Zinc Finger Transcriptional Regulators Enable Robust and Reliable Epigenetic Regulation in the Mouse Brain

Jisoo Lee, Kimberly Marlen, Qi Yu, Mihika Jalan, Hoang-Oanh Nguyen, Sarah Hinkley, Jason Eshleman, David Paschon, Mohammad Samie, Asa Hatami, Amy Pooler, Bryan Zeitler, Patrick Dunn

Sangamo Therapeutics, Inc., Richmond, CA

Genomic medicines have the potential to transform the treatment of neurodegenerative and neurodevelopmental diseases. Towards that end, we are developing zinc finger transcriptional regulators (ZF-TRs) to therapeutically modulate genes underlying neurological disorders. ZF-TRs are derived from naturally occurring human proteins and can be engineered to recognize specific genomic DNA sequences. Uncovering novel regulatory sites for highly specific epigenetic regulation (repression or activation) can require extensive empirical testing. Using our proprietary design algorithm, we generated hundreds of candidate ZF-TRs against multiple neurological disease targets to efficiently identify regulatory hot spots in both mouse and human genomes. We then developed an iterative and automated *in vitro* screening platform to test their on- and off- target activity in cell lines and cultured neurons before assessing their performance in animal models. In the first step of this workflow, we transiently transfected mRNA for hundreds of candidate ZF-TRs per target per species at multiple doses into human (SK-N-MC) or mouse (Neuro-2a) neuroblastoma cell lines. After 24 hours, we performed automated RT-qPCR analysis to assess changes in target gene expression. For each target, we identified unique regulatory sites permissive to regulation by a collection of active ZF-TRs. From these candidates, we selected dozens per target per species and manufactured AAV-ZF-TR vectors to examine their activity in primary (mouse) or iPSC-derived (human) neurons. We observed that ZF-TR performance in neurons was highly correlated with that in neuroblastoma lines. Notably, most of the ZF-TRs screened in neurons demonstrated potent and dose-dependent target gene regulation. Next, we evaluated AAV-ZF-TR specificity using high-throughput Affymetrix microarray analysis to examine the number of differentially expressed genes between ZF-TR and control-treated neurons. Using this approach, we identified several active ZF-TRs per target with few to no detectable off-targets. To confirm their activity *in vivo*, we delivered a subset of mouse-targeted AAV-ZF-TRs to wildtype adult mice and measured their impact on target gene expression in multiple brain regions by RT-qPCR analysis. All ZF-TRs tested showed robust target reduction in each of the brain regions examined. Our ability to engineer potent and selective ZF-TRs targeting novel regulatory sites for multiple targets and species highlights the potential of this epigenetic regulation platform to create genomic medicines for an array of nervous system diseases.

683 Too Much or Too Little: AAV-Based Gene Replacement Therapy for *SURF1*-Related Leigh Syndrome

Qinglan Ling, Matthew Rioux, Steven J. Gray

University of Texas Southwestern, Dallas, TX

SURF1(surfeit locus protein 1)-related Leigh syndrome (LS) is an early onset neurodegenerative disorder characterized by reduction in the assembly factor of complex IV, resulting in disrupted mitochondrial function. Patients with this disease show degenerations in multiple brain regions, including basal ganglia, diencephalon, brain stem and spinal cord. Here, we hypothesized that a functional gene replacement strategy could restore mitochondrial functions in LS caused by *SURF1* loss-of-function mutations. We have previously reported a codon-optimized version of the human *SURF1* (h*SURF1*) packaged within self-complementary adeno-associated virus serotype 9 (AAV9) viral vectors (AAV9/h*SURF1*) to drive strong and ubiquitous expression of *SURF1* in all organs (Vector-A), including the central nervous system (CNS). Our study suggested that Vector-A was effective in restoring abnormalities in the *SURF1* KO mice, and was safe in the WT mice for at least a year. However, the same vector led to inflammation and degeneration in multiple tissues of WT adult rats, including heart, liver, and dorsal root ganglion, most notably at 30 days post-dosing. In order to minimize the toxicity while maintaining the efficacy of the gene therapy, we modified the design of Vector-A to reduce the expression of *SURF1*, which led to the design of Vector-B, Vector-C and Vector-D. We compared the effectiveness of all four vectors in restoring complex IV activity in patient fibroblasts, which showed similar degrees of improvement. We further proceeded to test Vector-D (the vector that induces the lowest *SURF1* expression) in the *SURF1* KO mice. Our data suggested that Vector-D was able to improve COX activity in different tissues depending on the treatment age, dose and administration route, and it is safe in the WT rats. Our results further suggest that SURF1 overexpression may induce mitochondrial stress. Our ongoing studies involve optimizing the design of our transgene cassette to achieve ideal restoration of SURF1 in all tissues with a treatment scheme that can be safely and effectively translated to patients.

684 AAV1.NT3 Gene Therapy Ameliorates the Clinical Severity of Experimental Autoimmune Encephalomyelitis (EAE) Mouse through Immunomodulation

Lingying Tong[1], Burcak Ozes[1], Kyle Moss[1], Morgan Myers[1], Zayed Attia[1], Zarife Sahenk[1,2]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics and Neurology, Ohio State University, Columbus, OH

Introduction: Multiple sclerosis (MS) is a common demyelinating disease, affecting more than 2.5 million patients worldwide. MS is an autoimmune disease in which the patients' immune system attacks the myelin of the nerves in the brain and spinal cord, eventually causing demyelination and secondary axonal loss. The main causes of MS remain largely unknown, and there is currently no cure for the disease. Neurotrophin 3 (NT-3) is an important growth factor stimulating glial cell survival and differentiation, and stimulates axon growth and myelination. NT-3 is also known to have immunomodulatory and anti-inflammatory properties as we previously demonstrated in the

spontaneous autoimmune peripheral polyneuropathy (SAPP) mouse model for chronic inflammatory polyradiculopathy (CIDP) in humans. In this study, we used the chronic relapsing experimental autoimmune encephalomyelitis (EAE) mouse model to mimic MS disease and investigated the possibility of using AAV1.tMCK.NT-3 gene therapy, via intramuscular delivery into the EAE model to attenuate the disease process as a treatment approach. **Methods:** C57BL/6 mice at age of 8-12 weeks were immunized with synthetic myelin oligodendrocyte glycoprotein peptide (MOG_{35-55}, MEVGWYRSPFSRVVHLYRNGK) in complete Freund's adjuvant with Mycobacterium tuberculosis H37RA. For each mouse, 200 ug of MOG_{35-55} peptides and 200 ug H37RA were emulsified in CFA and injected subcutaneously into the flanks, followed by intraperitoneal injection of 400 ng pertussis toxin. A second dose of pertussis toxin was given after 48 h. AAV1.tMCK.NT-3 was delivered via intramuscular injection to the right gastrocnemius muscle (1.0xE11 vg in Ringer's lactate) at 21 days post EAE induction. This approach ensures continuous systemic effect of NT-3 through secretion from muscle into circulation. Mice were closely monitored using a clinical scoring system and functional studies and sacrificed at approximately 70 days post EAE induction. **Result:** Our data showed that AAV1. NT-3 gene therapy ameliorated the clinical severity of EAE. The clinical score showed substantial improvement of treated mice compared to untreated mice. The treated cohort performed significantly better in rotarod performance and grip strength tests compared to untreated counterparts. These data correlated with reduced expression of the pro-inflammatory cytokines, interleukin-1β (IL-1β), tumor necrosis factor (TNF-α), and interleukin-6 (IL-6) in both brain and spinal cord, in the NT-3 treated cohort. The treatment also increased the percentage of $CD3^+CD4^+CD25^+$and $Foxp3^+$ regulatory T cells (Tregs) in the spleens and lymph nodes of both male and female mice. When challenged by myobacterium, the dendritic cells from bone marrow of NT-3 treated mice also showed lower induction of TNF-α. **Conclusion:** In summary, our study demonstrated that AAV1.NT-3 gene therapy reduced the severity of EAE model of MS, possibly through modulation of the immune system. We show that circulating NT-3, following the transduction of muscle via AAV1.tMCK.NT-3 vector injection triggers tolerogenic immune responses by reducing the inflammation and increasing Treg cells in both spleen and lymph node. This proof-of-principle study demonstrates the potential of clinical translational path for AAV-delivered NT-3 for treatment of chronic progressive MS.

685 AAV9-Mediated Gene Therapy in a Knock-In Mouse Model of Infantile Neuroaxonal Dystrophy

Amy F. Geard[1], Sammie Whaler[1], Wenfei Liu[1], Giulia Massaro[2], Michael Hughes[1], Hemanth Nelvagal[1], Laura Poupon-Bejuit[1], Jessica Albutt[1], Krushni Lalji[1], Simon Waddington[2], Manju Kurian[3], Ahad A. Rahim[2]

[1]School of Pharmacy, University College London, London, United Kingdom,[2]University College London, London, United Kingdom,[3]UCL-Great Ormond Street Institute of Child Health, Great Ormond Street Hospital, London, United Kingdom

Introduction: Infantile neuroaxonal dystrophy (INAD) is a rare and lethal paediatric neurodegenerative disease. It is caused by biallelic mutations in the *PLA2G6* gene, which codes for the enzyme calcium-independent phospholipase A2. Patients present with progressive neurological symptoms between six months and three years of age, with mortality typically occurring by 10 years old. No disease modifying treatments are available and there is an urgent need to develop new therapies. Methods: We conducted an in-depth characterization of the *pla2g6-inad* knock-in mouse model. Following characterization, we investigated the therapeutic potential of an AAV9.h*PLA2G6* vector administered intracerebroventricularly to neonatal and juvenile *pla2g6-inad* mice. We investigated survival, behavioural parameters, and histological analysis to assess therapeutic efficacy. Results: The average lifespan of the model is reduced to approximately 14 weeks, with weight loss and behavioural decline from 9 weeks old. Neuropathology studies showed neuronal loss and neuroinflammation in the brain and spinal cord, along with autophagic and lysosomal accumulation. A long term-study over 30 weeks demonstrated that neonatally administered AAV9.h*PLA2G6* gene therapy resulted in a significant improvement in all parameters measured including survival, weight, locomotor function, and neuronal counts in both the brain and spinal cord. Furthermore, the autophagic function was restored and lysosomal accumulation was significantly reduced. Adult administrations to symptomatic mice have thus far shown increased survival of 21 weeks on average and improved behavioural function. Conclusion: This study provides novel insights into INAD disease pathology and cellular dysfunction in the CNS and suggests an AAV9-based therapy has potential to enable effective treatment of INAD. Further clinical translation studies are being undertaken with our industrial partner, Bloomsbury Genetic Therapies Ltd.

686 AAV9.CBA.BAG3 Gene Therapy Improves Survival and Function in the SOD1.G93A Mouse Model for ALS

Burcak Ozes[1], Lingying Tong[1], Kyle Moss[1], Morgan Myers[1], Zayed Attia[1], Zarife Sahenk[1,2]

[1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics and Neurology, Nationwide Children's Hospital and The Ohio State University, Columbus, OH

Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease caused by the degeneration of upper and lower motor neurons. While majority of ALS cases are sporadic, 10% of the cases are familial. Mutations in superoxide dismutase 1 (SOD1) gene, commonly seen in familial cases, cause production of misfolded proteins which form aggregates in cells, leading to loss of motor neurons. Misfolded proteins can be degraded using ubiquitin-proteasome system or autophagy-lysosome pathway (ALP), depending on several factors, such as state of the misfolding and abundance of aggregates. BCL2-associated athanogene 3 (BAG3) is one the cochaperones in ALP, shown to be upregulated in *in-vitro* and *in-vivo* models with mutant SOD1. In this study, we tested if overexpression of BAG3 mitigates motor neuron death, and consequently increases survival in the SOD1.G93A mouse model for ALS, alone or combined with Neurotrophin-3 (NT-3), a known supporter of neuronal survival. SOD1.G93A mice received AAV9.CBA.BAG3 ($4x10^{12}$ total vg) systemically at 40 (BAG3-40, n=3) and 70 (BAG370, n=4) days of age, prior to prominent intraneuronal aggregate formation (AF), and at day 100 (BAG3-100, n=5) when intraneuronal AF is obvious. The efficacy of circulating NT-3 secreted from muscle was tested with AAV1.tMCK.NT-3 ($1x10^{11}$ total vg) gene therapy via intramuscular injection (IM) at day 40 (NT-3-40, n=3), or as

part of the combinatorial therapy where both vectors were administered at day 40 (Combo-40, n=4) and day 70 (Combo-70, n=9). Ringer's lactate injected cohort (n=7) served as untreated (UT) control group. Mice were tested on rotarod and for grip strength weekly, starting at the time injection, and were perfused at endpoint with formalin. Anterior horn neurons were quantified in cresyl violet-stained cross sections. Survival of SOD1.G93A mice increased significantly in BAG3-100, NT-3-40, and Combo-70 cohorts. The mean age of death (days) was 141.9 ± 2.7 for UT, while it increased to 155.8 ± 2.0 in BAG3-100 (p=0.0073), 160.7 ± 1.3 in NT-3-40 (p=0.0019), and 153.4 ± 2.4 in Combo-70 (p=0.0099) cohorts. BAG3 gene therapy initiated on days 40 and 70, prior to notable AF did not increase the survival compared to BAG3-100 cohort, suggesting that time of BAG3 treatment is critical. BAG3-only cohorts and NT-3-40 performed significantly better in rotarod and grip strength, compared to UT cohort for various time points during the course of the study. Combo-40 surpassed the BAG3-40 and NT-3-40 cohorts, and Combo-70 exceeded the BAG3-70 cohort suggesting that combinatorial treatment approach is more beneficial than BAG3 or NT-3 alone. The quantitative histopathology assessing the number of neurons in the anterior horn area of lumbar segments from each cohort revealed that large neurons (>15 μm) were better preserved in Combo-40, Combo 70, BAG3-100 and NT-3-40 cohorts. We found no further motor neuron loss in these cohorts compared to UT, which died 2 weeks earlier, suggesting that the treatment decreased the natural rate of decline in number of neurons. This study shows that systemic AAV9.CBA.BAG3 gene therapy in the SOD1.G93A mouse model for ALS significantly improved survival and function, when introduced at the time of prominent intraneuronal AF associated with clinical signs of early paralysis. Our combinatorial gene therapy with AAV1.tMCK.NT-3, via IM delivery, further improved the function in this model. We believe this approach might offer therapeutic potential for other protein aggregate-related neurodegenerative disorders.

687 Intracerebroventricular AAV9 Gene Therapy in Neonates Improves Lifespan and Disease Progression over Later Treatment in a Mouse Model of Niemann-Pick Disease, Type C

Benjamin E. Epstein, Gabrielle M. Soden, Cristin D. Davidson, Arturo A. Incao, William J. Pavan

National Human Genome Research Institute, National Institutes of Health, Bethesda, MD

Niemann-Pick disease, type C1 (NPC1) is a rare, monogenic neurodegenerative disease affecting approximately 1:100,000 births in the United States causing severe neurological degeneration as well as peripheral symptoms, including hepatosplenomegaly. Though small molecule trials are currently in progress, there are currently no FDA-approved therapies for NPC1. AAV-based gene therapy has been shown to significantly extend lifespans and slow symptom progression in mouse models of NPC1. However, clinical realities may impact the preferred choice of delivery route and age of administration, and the specific relative impacts of treating the central nervous system (CNS) and the periphery has not been clearly shown. To establish the optimal delivery parameters for an efficacious AAV-based gene therapy for NPC1 and determine the relative significance of treating the CNS and peripheral organs, we compared the survival and disease phenotype progression of mice injected with AAV-NPC1 constructs at three different age/delivery route combinations. We found that while all treatments improved outcomes in mice, those treated as neonates via an intracerebroventricular (ICV) injection survived more than 2-fold longer and showed significantly slowed disease progression compared with mice treated at weaning age with either systemic or ICV delivery. We also found that treatment with an AAV8-NPC1 construct that does not reach the CNS had a significantly smaller impact on survival and disease phenotype than all treatments that reached the CNS. However, we observed that splenomegaly, a symptom common in NPC patients but rarely observed in NPC1 mouse models, can in fact appear as well in older neonatal ICV-treated mice. These findings suggest that earlier treatments focused on the CNS are optimal for extending survival and slowing disease progression in NPC1. They also demonstrate that while targeting the CNS is crucial for the most significant measures of disease progression, treatments that reach the periphery may also be important for further improving overall efficacy as well as for addressing liver and spleen pathology, among the most common clinical symptoms of NPC1.

688 Safe and Efficient Intra-CSF Delivery of AAV Vector in Nonhuman Primates

Chunjuan Song, Shai Huang, Jiayi Xu, Qian Lu, Xin Xin, Ying Zhou, Wei Hu, Hui Wang, Lijun Wang, Zhenhua Wu, Guo-Jie Ye

Exegenesis Bio Inc., Lower Gwynedd, PA

It has been challenging for adeno-associated virus (AAV) to efficiently transduce central nervous system (CNS) after intravenous (IV) administration, though novel blood-brain barrier (BBB)-crossing serotypes have been actively studied. Therefore, it is still highly needed for clinical applications to identify a safe and effective route of AAV administration to target CNS. To achieve CNS distribution, several ROAs have been applied, such as intraparenchymal, intracerebroventricular, and intrathecal (cisterna, or lumbar). Studies have demonstrated promising results that intrathecal AAV infusion leads to significant gene expression in the CNS, however recent studies conducted in nonhuman primates (NHPs) to compare intra cisterna magna (ICM) and intrathecal lumbar (IT) demonstrated discrepancies. In this study, self-complimentary AAV9-mediated gene expression of green fluorescent protein (GFP) driven by chicken beta actin (CBA) promoter at a dose of $3x10^{13}$ vector genome (vg)/animal was assessed in cynomolgus macaques with necropsy at Day 14 post dosage to compare ICM and IT lumbar administration. We characterized the AAV genome biodistribution by quantitative PCR (qPCR) and GFP protein expression by enzyme-linked immunosorbent assay (ELISA) and immunohistochemistry (IHC) in the CNS and peripheral system following ICM or IT lumbar dosage. AAV distribution and transgene expression (GFP) were high in spinal cord and dorsal root ganglia (DRG) after ICM or IT administration, and there were no significant difference of transgene expression in these tissues or peripheral tissues /nerves between ICM and IT injection. However, the transgene expression was higher in the brain when the AAV was infused in cisterna magna via ICM than lumbar area through IT administration. Intrathecal delivery via lumbar is a convenient dosing route due to the easy access and minimal invasiveness. However, the delivery strategy of ICM administration via suboccipital puncture in NHPs or translation to clinical practice is challenging because of the high risk of severe or

sometimes even fatal complications in animals or patients due to the medullary injury impedes. To overcome this hurdle, we utilized the catheter-mediated cisterna magna delivery strategy by adapting an intravascular microcatheter which can safely navigate in the spinal canal from lumbar section to the cisterna magna under fluoroscopic guidance. In this study, delivery of AAV into cisterna magna area when applied with microcatheter was as safe as IT dosing. No adverse effects were observed during infusion or post-dosage. These results suggest that both ICM and IT lumbar administration of AAV are excellent ROAs when AAV transduction in spinal cord or DRG is needed, whereas if the neurological disease requires brain neuronal transduction, ICM is a better ROA than IT lumbar. Remarkably, with the adaptation of microcatheter, the ICM delivery technique is a safe and minimally invasive alternative to direct infusion into the cisterna magna, achieving the distribution of AAV gene transfer to the brain.

689 Developmental Age Effects for AAV9/SLC6A1 Gene Therapy in a Mouse Model of SLC6A1 Related Disorder

Weirui Guo, Matthew Colby Rioux, Frances Shaffo, Yuhui Hu, Steven J. Gray

University of Texas Southwestern Medical Center, Dallas, TX

The human SLC6A1 gene encodes the highly conserved gamma-aminobutyric acid (GABA) transporter GAT-1, which is responsible for the reuptake of GABA into presynaptic neurons and glia. It is a key regulator for GABAergic signaling in the central nervous system (CNS). A subset of patients presenting with rare forms of infantile encephalopathy with intellectual disability (ID) have been shown to be heterozygous for loss-of-function mutations in SLC6A1. To test our hypothesis that broad delivery of the human SLC6A1 gene across the CNS using adeno-associated virus type 9 (AAV9) to restore normal GABAergic signaling can provide an effective treatment and long-term therapeutic benefit for SLC6A1-Related Disorder, we designed two AAV9 vectors with different promoters (one is a weak universal promoter - JeT; the other is a neuronal-specific promoter - MeP229) and conducted preclinical gene therapy studies using SLC6A1 knockout (KO) mice, a mouse model of SLC6A1, at different developmental ages. The two AAV9/SLC6A1 vectors were tested separately via intracerebroventricular (ICV) administration at neonate age and lumbar intrathecal (IT) administration at the age of postnatal day (PND) 7-10 or 28-35. Neonatal ICV administration of both vectors ($3x10^{11}$ vg per mouse) resulted in significantly reduced seizures assessed by EEG in both SLC6A1 KO and heterozygous mice, as well as improvement in several behavioral tests (fear conditioning, nest building, rotarod performance, and hindlimb clasping) in homozygous KO mice. However, some adverse effects (including death) were noted with both constructs after neonatal ICV treatment. IT administration ($7.5x10^{11}$ or $7.0x10^{11}$ vg for JeT and MeP229 constructs, respectively) to PND7-10 SLC6A1 KO mice showed moderate improvement, but treatment at PND 28-35 had no apparent treatment benefit. The treatment was tolerated well following IT administration at PND 7-10 or PND 28-35 in both KO and WT mice up to one year post-injection. It is not clear whether the stronger efficacy and toxicity seen by neonatal ICV administration is due to the much higher transduction efficiency by this route and age, or whether the earlier intervention was the main driver of efficacy and adverse effects. To increase the transduction efficiency at an older age, the MeP229-SLC6A1 construct was packaged into AAV-PHP.eB and dosed into PND23 mice by intravenous (IV) administration. All the PHP.eB/SLC6A1 treatments ($2x10^{10}$, $2x10^{11}$ or $1x10^{12}$ vg per mouse) still failed to reduce seizures in SLC6A1 KO or heterozygous mice, and the $2x10^{10}$ or $2x10^{11}$ vg doses only showed a moderate nest building behavioral improvement (the 1 $x10^{12}$ vg group wasn't assessed). While AAV-PHP.eB treatment increased the transduction efficiency of SLC6A1 at PND23, no adverse effects were observed across all the IV treated animals. Overall, our data demonstrate compelling efficacy when mice are treated at the newborn age, which is contrasted with a degree of adverse effects specific to this treatment age. Treatment at any older ages (PND7-10, PND23, and PND28) has thus far yielded only modest benefits, although treatment at these ages has lacked any adverse effects. It remains an open question as to which is the key driver of safety and efficacy with this approach: age of intervention or transduction efficiency.

690 An Engineered β-glucocerebrosidase with Improved Stability and Cross-Correction for the Potential Treatment of Gaucher Disease

Jacob Artz, Rachel Cathleen Botham, Christopher Schmitt, Victorino Miguel, Joseph Chen, Oluwayomi Akinkugbe, Londen Johnson, Kaysay Gebretsadik, Elizabeth Del Greco, Faezeh Sedighi, David Homan, Xingxiu Chen, Doug Millar, Jeremiah Heredia, Ouma Onguka, Hassibullah Afeeke, William Casey Hallows, Adam Silverman

Codexis, Inc., San Carlos, CA

Gaucher Disease (GD) is an inherited autosomal recessive lysosomal storage disorder resulting from mutations in the *GBA1* gene that lead to loss of function of the lysosomal enzyme β-glucocerebrosidase (GCase). The resulting accumulation of glucosphingolipids in peripheral macrophages (non-neuronopathic, Type 1) and neuronal cells (neuronopathic, Type 2 acute and Type 3 sub-acute) drives disease pathology in the periphery (splenomegaly, hepatomegaly, thrombocytopenia, and bone infarctions) and central nervous system (neuroinflammation), respectively. Although there are approved enzyme replacement therapies (ERT) for Type 1, there exists a clear unmet need for Types 2 and 3. In addition, the bimonthly burden of ERT infusion, the progression of symptoms despite treatment, and the persistence of bone lesions for some patients warrants development of a gene therapy with durable efficacy. GCase ERT bears a modified glycan structure relative to natively expressed protein, which is required for effective uptake into target cells. Further, wild-type (WT) GCase expresses poorly and is rapidly inactivated in human serum. Our approach to circumvent the intrinsic limitations of GCase protein was to identify GCase variants with exceptional expression efficiency, stability in circulation, and efficient uptake into macrophages. We applied our CodeEvolver® protein engineering platform to screen >5,000 GCase variants over three rounds of iterative directed evolution. The lead GCase variant expresses approximately 200-fold more active protein than WT GCase from Expi293 cells, is more stable in serum, and has increased activity in treated macrophages. Treatment of *GBA1* knockout macrophages with the engineered GCase variant clears glucosphingolipids from the cells efficiently. Finally, we discuss the translational potential for

the evolved *GBA1* transgene delivered to a mouse model of Gaucher disease via AAV. Collectively, our findings highlight the benefit of protein sequence optimization to generate GCase enzyme variants as the next generation of therapies to improve patient outcomes.

691 CNS Gene Therapy Spatially and Temporally Modulates Transcriptional Expression of Neurons and Oligodendrocytes in Canavan Disease

Anoushka Lotun[1], Morgan Mooney[1], Guangping Gao[1,2], Dominic J. Gessler[1,2]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Co-Corresponding, Author, MA

Gene replacement for neurodegenerative diseases using recombinant adeno-associated viruses (rAAVs) has made great strides in recent years, enabling clinical trials and the first FDA approved gene therapies. Neurodegeneration is progressive and key aspects for clinical intervention include insight into differential responses of gene therapy on brain regions and identifying disease stages that are too advanced for treatment. Using a progressive neurodegenerative disease model, Canavan disease (CD), we characterized region-specific effects of gene replacement on disease reversal and identified treatment stages at which neuropathological recovery is achievable. CD is caused by genetic mutations in aspartoacylase (ASPA), an enzyme found in oligodendrocytes. Defective ASPA affects oligodendrocyte and neuronal homeostasis, triggering progressive loss of both cell types. CNS expression of rAAV-delivered ASPA (rAAV-ASPA) in CD mouse models prevents cellular loss and rescues disease phenotypes. However, brain region response to treatment and the limits of treatment age on therapeutic effect is not known. We hypothesize that disease reversal is age-related and dependent on transcriptomic regulation following region-specific gene correction. Using symptomatic CD mice, we treated juvenile, adult, and mature adult ages with rAAV-ASPA to characterize region-specific transcriptional response of oligodendrocyte and neuronal lineages in an age-dependent manner. Without gene therapy, juvenile CD mice had more PDGFRa+ precursor oligodendrocytes, but significantly reduced pre-myelinating (Olig2+) and mature myelinating (MBP+) oligodendrocytes, two essential cell types required for axonal myelination. Remarkably this phenotypic shift in oligodendrocyte lineage was reversed as early as one-week in juvenile rAAV-ASPA mice and normalized by four-weeks, a finding which paralleled electron microscopy detection of augmented axonal myelination. These effects were largely brain-region dependent; i.e. the corpus callosum, a densely myelinated brain region affected in CD, exhibited significantly elevated PDGFRa+, Olig2+, and MBP+ cells post rAAV-ASPA, suggesting a potentially novel mechanistic effect of remyelination post-gene therapy. Interestingly, this increase of mature oligodendrocytes corresponded with greater expression of mature myelinated (RbFox3+) neurons and neuronal growth cones (Gap43+) in treated mice. Extent of disease progression plays a big role in gene therapy response. We found that adult CD mice with rAAV-ASPA achieved partial restoration of motor function and near-normalized neuropathology. However, therapeutic effect in mature adult CD mice was less pronounced, suggesting late-stage gene-therapy intervention may be difficult to achieve. In conclusion, rAAV-directed ASPA in the CNS can alter the transcriptional regulation of oligodendrocyte and neuronal lineage in a brain-region and age-dependent manner. These changes correlated with observed corrected histopathology, particularly of myelination, in the brain. By leveraging gene therapy in this age-dependent approach, we can better address avenues to treat advanced neurodegeneration in a clinical setting.

692 Determining the Role of CTCF Loops in Neuron Specific Paternal Imprinting of *UBE3A*

Orangel Gutierrez Fugon

UC Davis, Davis, CA

Angelman syndrome (AS) is a neurogenetic disorder caused by loss of *UBE3A*. Expression is biallelic in non-neurons but undergoes paternal imprinting in neurons. An antisense transcript is responsible for this silencing, but it is currently unknown how it is regulated. This transcript originates upstream at *SNRPN*, extends past *IPW* and continues antisense to *UBE3A* (*UBE3A-ATS*), however in non-neurons it terminates at *IPW*. The presence of binding sites for CTCF within this region suggest that it may perform a boundary function. The design strategy for *UBE3A* unsilencing to treat AS is limited by the lack of understanding of how tissue-specific imprinting is controlled at this locus. We have developed an innovative system to study this critical boundary region using epigenetic editing tools and a human neuronal precursor model. Since CpG methylation inhibits CTCF's binding and subsequent looping activity, I hypothesize that CTCF creates a chromatin loop in non-neurons that prevents the extension of *UBE3A-ATS* past *IPW*. Furthermore, CTCF is evicted by DNA hypermethylation in neurons, allowing extension of the antisense transcript past *IPW*. The objective of this research is to characterize the tissue-specific differences in methylation and chromatin structure at *IPW* that determine how *UBE3A* imprinting is controlled by CTCF loops. An immortalized human dopaminergic neuronal precursor cell line (LUHMES) that is not derived from neoplasia presents an epigenome that's closer to wild type. Using the undifferentiated LUHMES as a model for non-neurons and differentiated LUHMES to represent neurons reduces confounding variables and approximates a more direct comparison. Results show that *UBE3A-ATS* is only expressed in neuronally differentiated LUHMES, increases exponentially after day 4 and peaks at day 7 of being in differentiation media. To establish differences in CTCF loops between neuronal precursor cells and mature dopaminergic cells a HiChIP was performed on differentiated and undifferentiated LUHMES cells. The data was analyzed and compared using individual and concatenated samples at 5 kb bins. Four novel CTCF loop interactions unique to neurons were discovered for the Angelman locus. A 4C experiment has also been performed to validate the tissue specific differential looping seen in the HiChIP. In the future we will use dCas9 epigenetic editing to determine if these loops are sufficient and necessary to stop the extension of *UBE3A-ATS* past *IPW.* Use of the LUHMES cell culture model has the potential to accelerate the study of this *UBE3A* boundary region and reveal the role that chromatin loops may play in its regulation of *UBE3A-ATS*.

693 Extracellular Vesicle-Based Delivery of Silencing Sequences for the Treatment of Machado-Joseph Disease | Spinocerebellar Ataxia Type-3

David Rufino-Ramos[1], Kevin Leandro[1], Vítor Carmona[1], Inês Martins[1], Patrícia Albuquerque[1], Rita Fernandes[1], Carina Henriques[1], Diana Lobo[1], Rosário Faro[1], Rita Perfeito[1], Liliana Mendonça[1], Dina Pereira[1], Rui J. Nobre[1,2], Luis Pereira de Almeida[1,2,3,4]

[1]CNC-UC - Center for Neuroscience and Cell Biology of the University of Coimbra, University of Coimbra, Coimbra, Portugal,[2]ViraVector-Infrastructure of Viral Vectors Production for Gene Transfer, Coimbra, Portugal,[3]CiBB - Center for Innovative Biomedicine and Biotechnology, Coimbra, Portugal,[4]Faculty of Pharmacy of the University of Coimbra, Coimbra, Portugal

Machado-Joseph disease (MJD)/Spinocerebellar Ataxia Type 3 (SCA3) is the most common autosomal dominantly inherited ataxia worldwide. It is caused by an overrepetition of the trinucleotide CAG within the ATXN3 gene which confers toxic properties to the ataxin-3 (ATXN3) mRNA and protein. Despite no disease modifying treatment is available up to date, RNA interference technology has shown promising therapeutic outcomes but still lacks an efficient non-invasive delivery method to the brain. Extracellular vesicles (EVs) are cell-derived lipid membranes emerging as a promising delivery strategy due to their capacity to deliver small nucleic acids, such as miRNAs. miRNAs were found to be enriched into EVs due to specific signal motifs designated as ExoMotifs. In this study, we aimed at investigating whether ExoMotifs would promote the packaging of engineered miRNA-based silencing sequences into EVs to be used as therapeutic vehicles to the brain to treat MJD/SCA3 upon daily intranasal administration. We found that miRNA-based silencing sequences, associated with the ExoMotif GGAGGAG and the ribonucleoprotein A2B1 (hnRNPA2B1), retained the capacity to silence mutant ATXN3 (mutATXN3) and were 2.5-fold enriched into EVs.Furthermore, the bioengineered EVs containing the neuronal targeting peptide RVG on the surface significantly decreased mutATXN3 mRNA and protein levels in primary cerebellar neurons from MJD YAC 84.2 and in a novel dual luciferase MJD reporter animal model, upon daily intranasal administration. Altogether, these findings indicate that bioengineered EVs carrying miRNA-based silencing sequences can be used as a promising delivery vehicle for brain therapy.

694 Gene Editing Therapy in a Humanized *SOD1^{G93A}* Mouse Model of Amyotrophic Lateral Sclerosis

Linyu Shi[1], Dong Yang[1], Shenglin Xiao[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Amyotrophic lateral sclerosis (ALS) is a rapidly progressing neurodegenerative disease that usually causes respiratory failure and death within two to five years following disease onset. In Europe and the United States, about 2 to 5 out of 100,000 people are suffering from ALS. The estimated number of 2020 ALS cases across the 22 countries is 121,028 prevalent and 41,128 incident cases. About 10% of ALS patients are familial, and most of them are caused by mutations in genes such as *C9orf72, SOD1, TDP-43, and FUS*. Mutations of *SOD1* are associated with ~20% of familial ALS and ultimately induces neuronal death in both the brain and spinal cord. Knockdown of *SOD1* can effectively inhibit the death of motor neurons caused by the accumulation of mutant SOD1; therefore, SOD1 has become an important target for the treatment of ALS. At present, there are ASO and AAV-miRNA drugs targeting *SOD1* in clinical trials phase; however, no effective therapeutic drugs have been approved. **Methods**: To investigate the treatment efficacy of AAV carrying the system of high-fidelity Cas12i (hfCas12Max) and gRNAs targeting *SOD1* (gSOD1), we administrated AAV-hfCas12Max-gSOD1 in neonatal humanized *SOD1^{G93A}* mice (Day 0 to 1) via intrathecal (IT) injection. The indel efficiency and knockdown level of SOD1 protein were tested by PCR plus sequencing and western blot in spinal cord and the whole brain of humanized *SOD1^{G93A}* mice. The lifespan of humanized *SOD1^{G93A}* mice with or without AAV-hfCas12Max-gSOD1 was observed. **Results**: We evaluated the efficiency of *SOD1* knockdown in spinal cord and the whole brain and observed that indel ratio of *SOD1* gene reached 20.3% in lumbar (Fig. 1A). Additionally, the knockdown efficacy of SOD1 protein level was more than 90% in spinal cord of humanized *SOD1^{G93A}* mice at 2 weeks post injection (Fig. 1B), compared with that in control mice. Median survival for low-dose injected humanized *SOD1^{G93A}* mice was 49 days longer compared with humanized *SOD1 ^{G93A}* mice with PBS injection (153.8±5.96 days, representing a 32.8% extension of survival (Fig. 1C). Four of the twelve humanized *SOD1^{G93A}* mice treated with AAV-hfCas12Max-gSOD1 survived over 200 days, whereas no humanized *SOD1^{G93A}* mice treated with PBS lived past 161 days. **Conclusions:** Our findings provide a strong foundation and promising approach for the clinical application of AAV-hfCas12Max-gSOD1 to treat ALS patients with *SOD1* mutations. Our gene editing strategy may potentially increase the lifespan and improve motor function of patients with ALS for an impactful treatment in the near future.

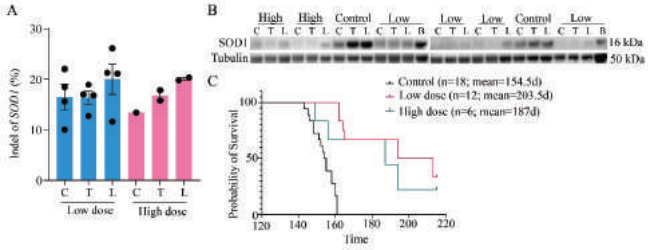

Figure 1. The treatment effect of AAV-hfCas12Max-gSOD1 in the humanized *SOD1^{G93A}* mice

695 Development of AAV-GBA1 Gene Replacement Therapy via Single-IV-Delivery with a Blood Brain Barrier Penetrant AAV Capsid

Charlotte Chung, Cassie Retzlaff, Jeff Thompson, Alexis Bloedel, Amy Bruce, Abigail Ecker, Joseph Clement, Elisabeth R. Knoll, Brian C. Ezell, Brett Hoffman, Tatiana Knox, Mathieu E. Voyager Therapeutics, Cambridge, MA

Lysosomal enzyme β-glucocerebrosidase (GCase) is encoded by the *GBA1* gene and loss of function (LOF) mutations in GBA1 result in a deficit of GCase activity. This leads to accumulation of glycosphigolipid-substrate such as glycosylsphingosine and glycosylceramide. Bi-allelic GBA1 mutations result in Gaucher disease (GD). Interestingly, heterozygous LOF mutations in GBA1 are also one of the greatest genetic risk factors for Parkinson's disease (PD) and Lewy Body Dementia. Enzyme replacement therapy (ERT) or substrate reduction therapy (SRT) are currently prescribed for GD patients to alleviate clinical impact in the peripheral organs. However, ERT/SRT are often unable to adequately cross the blood-brain barrier (BBB). Adeno-associated viral (AAV)-based gene replacement therapies using a BBB penetrant capsid could provide sustained correction of lysosomal storage disorders affecting the central nervous system (CNS). Successful transduction in areas affected in PD could potentially alleviate GCase activity deficits, reduce glycosphingolipid-substrate accumulation, and improve clearance of alpha-synuclein pathology. Optimized GBA1 transgenes were screened via *in vitro* and *in vivo* assays to demonstrate broad CNS biodistribution and target engagement in WT and GBA1 LOF mouse model. Single-intravenous delivery of top transgene candidates packaged into a mouse BBB-capsid (PHP.eB) were compared in the GBA1 LOF mouse model. Our data show increased biodistribution, expression, and GCase activities, accompanied by reduced neurofilament light chain, and rescue in motor impairment. These data support the testing in non-human primates (NHPs) to select optimal novel BBB-penetrant capsid(s), where we were able to show successful transduction in key areas affected in PD patients.

696 A Novel Small NPC1 Promoter Enhances AAV-Mediated Gene Therapy in Mouse Models of Niemann-Pick Type C Disease

Michael P. Hughes[1], Hemanth R. Nelvagal[1], Oliver Coombe-Tennant[1], Dave Smith[2], Claire Smith[2], Giulia Massaro[1], Laura Poupon-Bejuit[1], Frances M. Platt[2], Ahad A. Rahim[1]

[1]University College London, London, United Kingdom,[2]University of Oxford, Oxford, United Kingdom

Introduction: Niemann-Pick Type C Disease (NP-C) is a lethal monogenic neurovisceral lysosomal storage disease. In 95% of cases, it is caused by mutations in the *NPC1* gene that encodes for the lysosomal transmembrane protein, NPC1. There is currently no major disease modifying treatment available. We have previously demonstrated the potential of AAV9-mediated gene therapy as a treatment for NP-C. However, the large size of the *NPC1*cDNA sequence requires a small but efficient promoter to remain within the AAV packaging size limitation. Here, we investigated the ability of a minimal endogenous NPC1 promoter to reduce the size of the expression cassette and drive efficient human *NPC1* gene expression. **Methods:** We designed and investigated the therapeutic efficacy of a novel, minimal NPC1 endogenous promoter sequence compared to other commonly used promoters in gene therapy studies and clinical trials in mouse models of NP-C. Survival, locomotor function and neuropathology were assessed as readouts of efficacy. **Results:** Following neonatal intracerebroventricular injection into the CNS of both Npc1 KO mice and an Npc1 missense point mutant model, our minimal NPC1 promoter provided optimal therapeutic efficacy compared to all other promoters including a significant increase in survival, improved behavioural phenotypes, and attenuated neuropathology. Interestingly, the promoter activity was only optimal on an NPC1 deficient background and not in wildtype cells or wildtype mice, suggesting a specific activity that responds to disease phenotype. **Conclusion:** Our NPC1 minimal promoter is optimal compared to other commonly used promoter sequences in driving human *NPC1* gene expression in mouse models of NP-C. It is also small enough to allow efficient packaging of the AAV genome and suggests an AAV9-based gene therapy has potential for clinical development to enable effective treatment of NP-C. Further clinical translation studies are being undertaken with our industrial partner, Bloomsbury Genetic Therapies Ltd.

697 Engineering Ligand-Gated Ion Channels for Chemogenetic Modulation of Hyperexcitable Circuits in Neurological Disorders

Sania Therapeutics, London, United Kingdom

The fundamental cause of many neurological disorders can be attributed to the abnormal electrical activity of specific neural circuits. Normalizing activity in these dysfunctional neurons should therefore be a valuable avenue for the development of therapeutics, and ultimately the treatment of various nervous system conditions. However, for this to be a successful therapeutic approach, specific targeting is required so that anomalous neuronal activity can be corrected in the dysfunctional circuits without altering the properties of neighboring cells and brain regions. To advance the treatment of neural circuit disorders, Sania Therapeutics is leveraging a combination of intersectional technology platforms that allow for the targeted delivery of chemogenetic proteins through engineered AAV capsids and promoters. This approach will allow us to specifically modify neural circuit activity in disease states while minimizing side effects associated with current therapies. Chemogenetics refers to the alteration of electrical activity in neurons via the use of a genetically delivered protein that responds to a systemically delivered ligand. From a therapeutic perspective, the ideal chemogenetic system would have several properties. i) Minimal effects on baseline neuronal activity without the presence of an activator; ii) Potent and titratable effects on neuronal activity in response to

an activator; iii) validated efficacy in humans.Here we present data showing the efficacy of two chemogenetic cargo candidates for reducing excitability in hIPSC neurons. Using patch clamp electrophysiology, we assessed the effect of cargo expression on baseline neuronal excitability (no activator) and sensitivity to low doses of a specific cargo activator. Our data show that AAV-mediated expression of our lead candidate, SRX-C490, has no effect on baseline firing in hIPSC neurons, but low doses of activator significantly reduced excitability. In contrast, the activator has minimal effect on GFP transfected control neurons. Next, we attempted to increase activator potency using a rational design approach to mutate the genetic cargo, named SRX-C500. SRX-C500 showed increased sensitivity to the activator for threshold (rheobase) and sub-threshold (resting membrane potential) metrics, with larger effect sizes seen at the same doses of activator used with SRX-C490. However, SRX-C500 expression also potently suppressed baseline action potential firing, suggesting additional modifications are needed to reduce the baseline effect whilst maintaining activator sensitivity. Both chemogenetic proteins provide a potent means to develop new therapies based on altering neuronal activity. Due to the lack of effect on baseline excitability and high sensitivity to activator in hIPSC-derived neurons, SRX-C490 is now being tested as an intramuscular delivered, AAV treatment for motor neuron hyperexictability in an in vivo mouse model of spasticity.

698 Low-Dose Intracerebroventricular Delivery of a Second-Generation AAV Gene Therapy for Spinal Muscular Atrophy Achieves Efficient and Toxicity-Free Motor Function Rescue in Mice

Xiupeng Chen[1], Qing Xie[1], Hong Ma[1], Yijie Ma[2], Leila Jalinous[2], Jun Yang[2], Yunxiang Zhu[2], Qin Su[1], Phillip WL Tai[1], Guangping Gao[1], Jun Xie[1]

Onasemnogene abeparvovec (brand name Zolgensma®) is an FDA-approved adeno-associated virus (AAV) vector gene therapy that has been a significant breakthrough for treating infants with SMA. The vector produces ubiquitous expression of the human survival motor neuron 1 transgene under the cytomegalovirus enhancer/chicken β-actin promoter (*CMVen/CB-hSMN1*). However, the high intravenous (IV) dose required for efficacy (1.1E+14 vg/kg) can cause systemic adverse events, most commonly gastrointestinal (elevated liver transaminases and vomiting), but also hematologic (thrombocytopenia, thrombotic microangiopathy, increased prothrombin time) and cardiac (elevated troponin I). The US prescribing label for onasemnogene abeparvovec includes a black box warning of acute liver injury and acute liver failure. To improve upon the safety and efficacy of gene therapy for SMA, we developed a novel second-generation (2nd-gen) *hSMN1*-AAV gene therapy vector consisting of the endogenous *SMN1* promoter and a codon-optimized *hSMN1* transgene. In a previous head-to-head comparison, our 2nd-gen vector showed therapeutic advantages over a "benchmark" vector, whose design is identical to onasemnogene abeparvovec when administered intravenously to SMA mice, including longer life span, absence of liver toxicity, and better restoration of muscle function. To identify the capsid and route of administration that provides the best delivery to brain and spinal cord, we tested the 2nd-gen and benchmark constructs packaged into AAV9 or AAVrh10 capsids and delivered by intracerebroventricular (ICV) injection into SMA mice at P0. We compared the therapeutic outcomes of the four vectors at 3.3E+13 vg/kg (high dose) or 1.1E+13 vg/kg (low dose). At the high-dose, the AAV9-2nd-gen vector outperformed the other three vectors in survival, weight gain, righting reflex and the rotarod test, whereas the AAVrh10-2nd-gen vector performed the best in the grid test. At the low dose, the AAV9-2nd-gen vector also performed the best, followed by the AAVrh10-2nd-gen, AAV9-benchmark, and AAVrh10-benchmark vectors. We conclude that the 2nd-gen vector provides better efficacy than the benchmark vector following ICV delivery in both AAV9 and AAVrh10 serotypes. Western blot analysis demonstrated higher SMN1 protein expression in the brain and spinal cord of SMA mice treated with the 2nd-gen vector than with the benchmark vector, irrespective of the capsid used. Abundant SMN1 protein expression occurred in the dorsal root ganglia (DRG) of SMA mice in all treatment groups, but no clear evidence of DRG-related toxicity was observed during the 90-day study period. We injected the AAV9-2nd-gen vector into wild type mice at a dose of 1.0E+14 vg/kg by ICV and found no abnormalities associated with DRG toxicity for up to one year. Intravenous delivery of AAV9-2nd-gen at 3.3E+14 vg/kg and ICV delivery at one-tenth the dose (3.3E+13 vg/kg) produced similar rescue of lifespan and body weight gain. Importantly, ICV delivery achieved better motor function improvement than IV delivery, as determined by the righting reflex, grid test and rotarod test. Conversely, IV delivery was more efficient in reducing SMA disease-related complications observed in peripheral tissues, such as tissue necrosis of the ear, eye, and tail. In summary, we have engineered novel AAV based 2nd-gen vectors for SMA gene therapy with transgene expression that better mimics the physiological levels of SMN1 in transduced tissues. When delivered by ICV administration, the AAV based 2nd-gen vectors have the potential to be a safer, more effective, and more efficient clinical approach for treating SMA.* **G.G., and J.X are co-corresponding authors**

699 Characterization of In-Vivo Models of the Pediatric Neurodegenerative Disorder BPAN

Maria Carla Carisi[1], Martha Bishop[1], Madison Sangster[1], Louis-Jan Pilaz[2], Brandon L. Meyerink[2], Yulia Grishchuk[1]

[1]Center for Genomic Medicine, Massachusetts General Hospital and Harvard Medical School, Boston, MA,[2]Pediatrics and Rare Diseases Group, Sanford Research Institute, University of South Dakota, Sioux Falls, SD

Beta-Propeller Protein-Associated Neurodegeneration (BPAN) is a rare neurologic disease associated with early developmental delays and progressive neurodegeneration with movement disorder starting in adolescence. This X-linked disease is caused by mutations in the WDR45 gene encoding WIPI4, a WD40 repeat-containing PtdIns(3)P binding protein involved in autophagosome formation. There is currently no therapy for this disease, and little is known about the molecular mechanisms behind its pathological manifestations. The goal of this study is to test whether AAV-mediated WDR45 gene expression can rescue disease phenotype in BPAN mouse and cell models. To achieve this goal, we first set out to characterize BPAN mouse and cell models and establish disease-relevant outcome measures. BPAN

mouse model, *WDR45* $^{c.ex9+g>a/Y}$ mice, were obtained from the national public repository system for mutant mice (MMRRC) and mimic the human variant c.830+1G>A documented in a BPAN patient. The mice were successfully bred to establish an in-house colony, and their phenotype has been evaluated using a battery of tests. In the open field test, starting at two months of age *WDR45* $^{c.ex9+g>a/Y}$ mice exhibit increased track length, ambulatory events and walking time compared to litter-, sex- and age-matched WT controls. This trend persists in older naïve mice tested in the open field test at 11.5 months of age. The observation of increased ambulatory activity is indicative of hyperactivity in BPAN mice and is consistent with clinical observations of attention deficits and hyperactivity in BPAN children, and therefore can be a disease-relevant outcome measure for assessing preclinical efficacy in this model. Starting at 2 months, mice were tested monthly in the rotarod apparatus, until they reached 11 months of age. No difference was detected in the younger animals, while at 11 months *WDR45* $^{c.ex9+g>a/Y}$ mice fall of the rod sooner compared to controls, suggesting a motor function, balance and coordination deficits later in the course of disease. However, worsening of the rotarod performance was paralleled by weight gain in *WDR45* $^{c.ex9+g>a/Y}$ mice that become significant starting at 9 months of age. Weight gain in *WDR45* $^{c.ex9+g>a/Y}$ mice may be a confounding factor for rotarod performance in mice, and therefore evaluation of motor function, balance and coordination warrants further investigation. In addition to behavioral tests, we used a "neuroexam" panel of short tests to evaluate overall neurologic health, including righting reflex, crossed extensor reflex, forelimb and hindlimb placing responses, grasp, postural, rooting reflexes, placing, visual placing, eye blink and acoustic startle responses and negative geotaxis. Neuroexam showed no significant differences between *WDR45* $^{c.ex9+g>a/Y}$ and *WDR45* $^{+/Y}$ mice, suggesting intact basic sensory function. Our histopathological analysis of post-mortem brain tissue revealed astrogliosis and microgliosis in the cortex of 3-month-old *WDR45* $^{c.ex9+g>a/Y}$ mice, and in the striatum at 6 months of age. Evaluation of histopathological hallmarks of neuronal health/neurodegeneration is currently in progress. Overall, our data show that *WDR45* $^{c.ex9+g>a/Y}$ mouse model mimic major manifestations of the human disease, and is a great tool for BPAN gene therapy efficacy testing.

700 AAV-Mediated Gene Therapy to Target the Progressive Neurodegeneration in a Mouse Model of Xeroderma Pigmentosum - Cockayne Syndrome (XP-CS)

Audrey L. Daugherty[1], Monika Chauhan[1], Fatemeh (Ellie) Khadir[1], Alexandra Hoffman[2], Silveli Suzuki-Hatano[1], Skylar A. Rizzo[3], Wilbert P. Vermeij[4,5], Jan H. J. Hoeijmakers[4,5,6], Peter B. Kang[1], Christina A. Pacak[1]

[1]Department of Neurology and Paul and Sheila Wellstone Muscular Dystrophy Center, University of Minnesota, Minneapolis, MN,[2]University of Maryland, Baltimore, MD,[3]Medical Scientist Training Program, Mayo Clinic, Rochester, MN,[4]Princess Maxima Center for Pediatric Oncology, Utrecht, Netherlands,[5]Oncode Institute, Utrecht, Netherlands,[6]Department of Molecular Genetics, Erasmus University Medical Center, Rotterdam, Netherlands

The process of DNA repair is critical for the maintenance of genome integrity and stability within cells throughout an organism. Pathogenic variants in genes expressing proteins involved in DNA repair mechanisms can lead to serious multi-organ dysfunction. Xeroderma pigmentosum (XP) and Cockayne Syndrome (CS) are rare autosomal recessive disorders arising from deficiencies in proteins involved in the nucleotide excision repair (NER) pathway, a key component of DNA repair. Patients with XP and CS have no disease altering therapy available, beyond supportive care. Xeroderma pigmentosum complementation group G (XPG) is a DNA endonuclease responsible for the 3' incision made during NER. XPG is encoded by the *ERCC5* gene and pathogenic variants in *ERCC5* result in a disorder with characteristic skin photosensitivity. Approximately 30% of XP patients develop a more severe form of the disease that includes accelerated aging, neurodegeneration and other symptoms similar to those observed in CS patients including microcephaly, growth defects, hearing loss, and cognitive disability. This more severe form of the disease is referred to as XP-CS. The goals of this study were to characterize XP-CS related physiological and neurological outcome measures in an XPG mouse model to provide a platform for assessing the safety and efficacy of adeno associated virus (AAV)-mediated gene therapies, and then to test a candidate AAV gene therapy in this model. Age matched Xpg-/- and wild-type (WT) sibling control mice were evaluated for the following over a 12-week period: body length, weight, ataxia, tremors, and kyphosis. Xpg-/- mice showed significant growth defects from birth as compared to sibling controls. By 10 weeks of age all Xpg-/- mice had developed severe ataxia, tremors, and kyphosis. The severity of neurodegeneration as evaluated through weekly hind limb clasping scores, showed a significant increase in score for Xpg-/- mice as compared to WT controls. Further assessments included locomotor activity tracking (ActiTrack) and indirect calorimetry. Xpg-/- mice were hypokinetic, travelled significantly shorter distances, and displayed a reduced metabolic rate compared to WT mice. Tandem mass tagging (TMT) based global proteomic analyses of Xpg-/- mouse brains identified a total pf 2748 proteins, out of which 198 showed significantly altered levels ($p<0.01$). An *AAV9-ERCC5* gene therapy vector was administered to 6-week-old Xpg-/- mice through intrathecal (IT) injections at a dose of $1x10^{12}$ vg/kg. This treatment strategy delayed the onset of disease symptoms and led to a longer lifespan in treated mice as compared to untreated Xpg-/- controls. Full tissue evaluations are underway. In parallel, continued refinement of the physiological and neurological outcome measures in this animal model and further preclinical testing of our gene therapy strategies will promote further development of this approach towards future human clinical trials for this group of DNA repair disorders.

701 Engineered Human Blood-Brain Barrier Microfluidic Model for Assessing Permeability of Cell and Gene Therapies into the CNS

Munzareen Khan[1], Andrew Brady[2], Lakshmi Raj[3]

[1]NIBR Biologics Center, Novartis Institutes of BioMedical Research, Cambridge, MA,[2]NIBR Informatics, Novartis Institutes of BioMedical Research, Cambridge, MA,[3]NIBR Biologics Center, Novartis Institutes for BioMedical Research, Cambridge, MA

Efficient delivery of cell and gene therapies following noninvasive delivery to the central nervous system (CNS) remains a formidable challenge posed by various anatomical and physiological barriers within CNS, most notably, the blood-brain barrier (BBB). Due to

challenges in translating results from animal models to the clinic, relevant *in vitro* human BBB models are needed to assess permeability and enable design and selection of BBB-penetrant therapies for neurological disorders. To address this, we are developing an *in vitro* microfluidic human BBB model for screening and evaluation of therapeutics targeting the CNS. Microfluidic 3D co-culture models can mimic the physiological microenvironment of the BBB and address discordant performance of drugs observed between species. Moreover, implementation of this platform during early stages of drug discovery can accelerate the development of therapies. Thus, our *in vitro* BBB model is a promising tool to study transport mechanisms and aid in the development of cell and gene therapies with increased brain penetrance.

702 A Novel Gene Therapy Approach for ALS by Overexpressing the Pleiotropic Chronokine α-Klotho

Sergi Verdés[1,2,3], Mireia Herrando-Grabulosa[1,4,5], Rubén Guerrero-Yagüe[1,2,3], Joan Roig-Soriano[1,2,3], Núria Gaja-Capdevila[1,4,5], Marc Leal-Julià[1,2,3], Andrea Onieva[1,2,3], Laura Rodriguez-Estevez[1,2,3], Javier Del Rey[1,2,3], Neus Hernández[1,4,5], Miguel Chillon[1,2,3,6,7], Xavier Navarro[1,4,5], Assumpcio Bosch[1,2,3,5]

[1]Institute of Neuroscience, Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain,[2]Department of Biochemistry and Molecular Biology, Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain,[3]Mixed Unit UAB-VHIR, Vall d'Hebron Research Institute, Barcelona, Spain,[4]Department of Cell Biology, Physiology and Immunology, Universitat Autònoma de Barcelona (UAB), Cerdanyola del Vallès, Spain,[5]Centro de Investigación Biomédica en Red Enfermedades Neurodegenerativas (CiberNed), Instituto de Salud Carlos III, Madrid, Spain,[6]Viral Vector Production Unit (UPV), Bellaterra, Spain,[7]Institut Català de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

In amyotrophic lateral sclerosis (ALS), muscle denervation and degeneration of motoneurons result in progressive muscle weakness and atrophy. Motor impairment leads to loss of autonomy, need for intensive care and early death of the patients, without effective treatments being available. Preventing axonal detachment from muscles, protecting motoneurons and promoting reinnervation are key to improve the functional outcome of ALS. For preserving neuromuscular function in the SOD1^{G93A} mouse model, we synergically influenced on motoneuron terminals and muscles by boosting the secretion of α-Klotho in skeletal muscles. α-Klotho is a pleiotropic chronokine with an excellent profile as neuroprotective and myoregenerative agent by means of anti-oxidative and anti-inflammatory properties, promoting myelination, protecting from excitotoxicity, and maintaining mitochondrial ultrastructure and function. To overexpress α-Klotho in the skeletal muscles of SOD1^{G93A} mice, AAV8 vectors were systemically administered at a dose of 3x10^{14} vg/kg at an early stage of the disease. Secretion of α-Klotho by muscles enhanced motor function and strength of the animals and delayed the onset of the disease. Neuromuscular functional improvement was reflected as increased compound muscle action potential (CMAP) amplitudes and by larger size and number of functional motor units of hindlimb muscles compared to mock-treated controls. α-Klotho-treated SOD1^{G93A} mice showed more surviving motoneurons and a significant reduction in microglial and astroglial reactivity in the ventral horn of the spinal cord. A greater amplitude of the motor evoked potentials (MEPs) also evidenced improved connections between corticospinal and spinal motoneurons. At the neuromuscular level, there was a higher number of occupied motor endplates and a preserved mass of the muscles. In view of the high doses of AAV8 needed to reach therapeutic efficacy, we moved to a myotropic AAV vector. With a 20-fold decrease in the dose, we achieved higher preservation of neuromuscular connectivity, motor performance and strength, and delayed the disease onset in SOD1^{G93A} mice, even further than with the AAV8-α-Klotho treatment. More importantly, when SOD1^{G93A} mice were treated at 11 weeks of age, when already symptomatic, muscle overexpression of α-Klotho slowed down the progressive decline of the neuromuscular and motor function characteristic of SOD1^{G93A} mice. Overall, our results provide evidence that the overexpression and secretion of α-Klotho in muscles can promote functional improvement in ALS and may open a new avenue for the treatment of this devastating disorder.

703 Development of an AAV Gene Therapy for Hereditary Spastic Paraplegia Type 4 (SPG4-HSP)

Erin F. Hall[1], Jillian Gallagher[1], Toloo Taghian[1], Abby McElroy[1], Hector Ribeiro Benatti[1], Rachel Prestigiacomo[1], Stephanie Bertrand[2], Emanuela Piermarini[3], Liang Qiang[3], Peter Baas[3], Miguel Sena-Esteves[1], Heather L. Gray-Edwards[1]

[1]Horae Gene Therapy Center, University of Massachusetts Chan Medical School, Worcester, MA,[2]Tufts University Cummings School of Veterinary Medicine, North Grafton, MA,[3]Department of Neurobiology & Anatomy, Drexel University College of Medicine, Philadelphia, PA

Hereditary spastic paraplegia type 4 (SPG4-HSP) is an inherited neurodegenerative disorder and is the most common form of hereditary spastic paraplegia (HSP). SPG4-HSP is an autosomal dominant disease caused by mutations in the SPAST gene that encodes the microtubule severing enzyme spastin. It is considered that SPAST mutations not only disrupt the physiological functions of spastin, but elicit toxic gain-of-functions by the mutated gene products. Different mutations in the SPAST gene have been described, however the genotype-phenotype correlation remains unclear, even among affected members of the same families. SPG4-HSP has been classified in two major forms, termed pure and complex. Pure SPG4-HSP is the most common and is characterized by progressive spasticity of the legs, leading to stiffness and gait defects. Symptoms of complex SPG4-HSP include muscle weakness in the legs but can also include loss of sensation in the feet, and cognitive impairment among others. The age of symptom onset is variable, but most commonly begins in early adulthood. We have developed several dual function AAV vectors encoding wild-type human spastin and a micro RNA (miRNA) to silence the endogenous alleles. We delivered these AAV vectors into wild-type mice (n=10) by neonatal intracerebroventricular injection (4E10 vg/mouse) at postnatal day 1 and sacrificed them at 4 weeks of age. We are assessing spastin expression, silencing of the endogenous spastin mRNA, and biodistribution in the CNS and peripheral organs using western blot and qPCR. Our team is also conducting efficacy

studies in an SPG4 mouse model using a first generation AAV-SPG4 vector. A similar disease has been described in Brown Swiss cattle, also caused by a mutation in the SPAST gene, called Bovine Spinal Dysmyelination (BSD), more commonly known amongst farmers as Spinal Dysmyelination (SDM). Notably, the bovine disease presents a more severe phenotype than humans and affected calves are unable to stand at birth. We have obtained cattle with BSD to use as a large animal model of SPG4 and further test the efficacy of our vectors. Altogether, these combined studies in small and large animal models will help develop a treatment for patients with SPG4-HSP.

704 High-Throughput Quantitative Neurohistology for Gene Therapy Vector Evaluation

Chris Martin Hempel

Expressive Neuroscience, Syracuse, NY

In order to effectively treat disease, in vivo gene therapy vectors need to restore normal expression levels of the disease-relevant protein. This requires not only that the vector cross the blood brain barrier, but also that it deliver the payload to the appropriate regions of the brain, and the appropriate cell types. Furthermore the correct level of expression must be acheived in a sufficient portion of the targeted cells. Among all the preclinical methods commonly used to measure gene therapy payload delivery , neurohistology is uniquely positioned to illuminate all of the questions above. However, neurohistology as typically practiced is neither quantitative or capable of high throughput data generation and analysis. Expressive Neuroscience has created a platform that reenvisions histology for gene therapy discovery. Using streamlined lab protocols in conjunction with machine-learning assisted informatics we are able to automate measurement of target protein expression in thousands of cells in a typical experiment. Here we show, in the context of a rodent Rett syndrome model, how our platform can be used to quantitatively map payload expression across the brain at a cellular scale to support gene therapy discovery efforts.

705 Increased CNS Transduction is Realized Following Peripheral Injection in Animals Suffering from Experimental Autoimmune Encephalomyelitis

Geoffrey D. Keeler[1], Cristina D. Gaddie[2], Christopher Chan[2]

[1]University of Florida, Gainesvile, FL,[2]University of Florida, Gainesville, FL

Multiple Sclerosis (MS) is the prototypical neuro-inflammatory demyelinating disease. Within MS, the development focal lesions is considered a hallmark and leads to axonal damage, axonal death, and progressive disability in late disease stages. Current MS therapies supress the inflammatory response within the CNS, only a portion of disease. Currently, there are no FDA approved treatments for combating demyelination.Remyelination is the regenerative process where new myelin sheaths are formed and axonal function is restored. Within MS, remyelination occurs but is inefficient and ultimately fails in the majority of lesions. Thus, induction of remyelination has been postulated as an effective treatment for MS. This is supported by the fact that patients with a higher capacity to remyelinate show lower levels of disability. However, many obstacles impede the development of effective therapeutics to induce remyelination. Two such obstacles include: (i) crossing the blood brain barrier (BBB), (ii) delivering therapeutics specifically to the site where they are needed, the demyelinating lesion. Adeno-associated virus (AAV) is one of the most widely used vector platforms. Some AAV serotypes are capable of crossing the BBB. Of these, AAV9 is the leading serotype for targeting the CNS. Importantly, AAV9 efficiently transduces astrocytes, a major cellular component of demyelinating lesions. Thus, the AAV platform represents a novel treatment modality capable of delivering therapeutics to lesions to induce remyelination. However, AAV9 is inefficient at crossing the BBB when injected i.v. Instead, direct CNS injections are often required for sufficient transduction. These techniques are invasive in nature and have poor CNS bio distribution. An ideal technique would be one that was minimally invasive, resulted in high CNS transduction levels, and achieved excellent biodistribution throughout the CNS.In MS, and its animal model experimental autoimmune encephalomyelitis (EAE), perturbations in the BBB occur allowing entrance of immune cells into the CNS. We hypothesized that this could be leveraged by AAV to gain access to the CNS resulting in improved expression and transduction. In previous work, we showed increased transgene expression in EAE animals though it was unclear if this was due to improved AAV transduction or a result of neuronal inflammation present in our model. Here we show that improved CNS transduction is realized in animals suffering from EAE following a peripheral injection (Fig 1). In the brain, ~6 fold increased transduction was seen in EAE animals as compared to non-EAE controls that received AAV (Fig 1A). In the spinal cord, the primarily affected CNS region in EAE, a ~56 fold increase was seen in EAE animals as compared to controls (Fig 1B). Further, excellent biodistribution of transgene expression resulted with expression being seen in all regions of the brain (Fig 1C) and spinal cord (Fig 1D). Thus, peripherally injected AAV holds promise as a therapeutic for the induction of remyelination in multiple sclerosis.

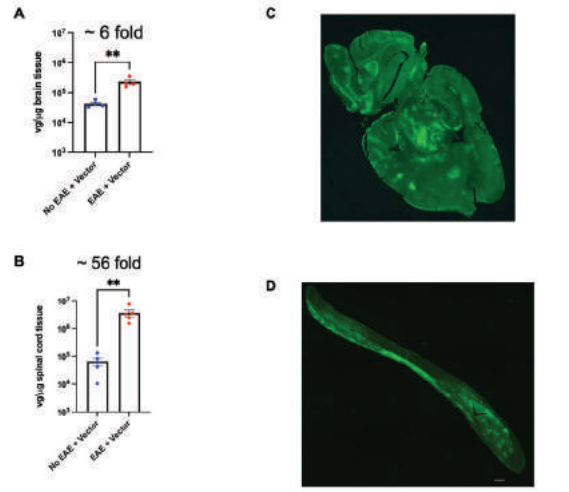

Figure 1: Transduction was evaluated in the CNS of animals following a single peripheral injection. In the brain, a ~6 fold increase in transduction occurred in EAE animals as compared to controls (**A**) In the spinal cord, a ~56 fold increase was seen in EAE animals as compared to controls (**B**). Transgene (eGFP) was also seen in all regions of the brain (**C**) and spinal cord (**D**) showing excellent biodistribution of our vector throughout the CNS. Green is eGFP expression under the control of a truncated GFAP promoter, images taken at 2x, scale bar = 500 µm.

706 AAV Gene Therapy for *GNAO1* Disorders

Tyler Mola[1], Hannah Villeneuve[1], Dasha Khvorova-Wolfson[1], Simon Wentworth[2], Pamela St Louis[1], Rrita Daci[3], Ana Rita Batista[1], Miguel Sena-Esteves[3]

[1]Neurology / Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]University of Massachusetts Medical School, Worcester, MA,[3]UMass Chan Medical School, Worcester, MA

Introduction: Mutations in the *GNAO1* gene cause severe neurologic disability including epilepsy and motor dysfunction. The *GNAO1* gene encodes for the $G\alpha_o$ subunit of a heterotrimeric G protein, comprising two isoforms. The pathophysiology related to this monogenetic defect is not fully understood and can be related to gain of function or loss of function. Here we will use a heterozygous knock-in GNAO mouse model ($GNAO^{+/R209H}$) that is genetically similar to humans, and test the therapeutic effect associated with either increasing, or silencing and replacing *GNAO1*. Firstly, we will utilize AAV to supplement GNAO1 isoforms. Alternatively, we will use a dual function AAV vector encoding artificial miRNA to silence endogenous mutated *GNAO1* and express the normal gene. Our goal is to simultaneously understand disease origin and create treatment modalities. **Methods:** We built two monocistronic AAV vectors, each encoding a GNAO1 isoform (GNAO1.1 and GNAO1.2) driven by a CBA promoter. In parallel, we designed a bicistronic AAV vector encoding both GNAO1 isoforms from a centrally located bidirectional promoter. All vectors were transiently transfected into human HEK293T cells, followed by western blot analysis of GNAO1, HA-tag or myc-tag. We then analyzed AAV-derived GNAO1.1 and GNAO1.2 expression levels in transfected cells by qRT-PCR using isoform-specific Taqman assays. To move these experiments *in vivo*, we utilized the $GNAO^{+/R209H}$ mouse model to first study its natural history and then understand treatment efficacy and toxicity. We tested the AAV-GNAO1 vectors by neonatal ICV injection in our mouse model, as well as in WT animals for toxicity assessment. Open field test was utilized to assess phenotypic differences between AAV injected mice and PBS controls. **Results**: Western blot analysis from *in vitro* transfection of monocistronic (scAAV9-GNAO1.1 and scAAV9-GNAO1.2) and bicistronic (AAV9-GNAO1.1/1.2) vectors demonstrated expression of respective GNAO isoforms and qRT-qPCR data revealed appropriate mRNA from AAV-derived GNAO protein i*n vitro.* However, behavioral tests, namely open field test, showed no phenotypic differences between treated and untreated mice. Whereas a comparison study between WT and Hz mice had shown a significantly increased hyperactive state in the Hz mice. There was no evidence of vector toxicity. We are now working on our second approach using the dual vector strategy, and we have selected candidate miR sequences to silence endogenous GNAO1 mRNAs. **Conclusions**:Our data shows that all GNAO1 vectors are expressed in HEK293T cells, as evidenced by protein expression of GNAO, and by qRT-PCR. In our natural history study, we found that heterozygous $GNAO1^{+/R209H}$ mice have increased hyperactivity on the open field behavioral test. Our hypothesis is that altered signaling in the striatum of heterozygous $GNAO1^{+/R209H}$ mice is the major driver of their hyperactivity phenotype. Although our initial treatment study analytics showed no difference in mouse behavior, increasing vector dose may have an effect, and therefore we are currently enrolling more animals in a higher dose studyThis study also provides the most efficient miR^{GNAO1} which we will use to create dual function AAV vectors capable of silencing the endogenous GNAO1 mRNA and expressing normal $G\alpha_o$ protein. Therefore, paving the way for a potential treatment for this devastating disease.

707 Development of an Optimized AAV Gene Therapy Treatment for XLRP Caused by RPGR

Qiutang Li[1], Chao Cheng[2], Ting Liu[2], Bin Li[2]

[1]Neurophth Therapeutics Inc, San Diego, CA,[2]Wuhan Neurophth Biotechnology Limited Company, Wuhan, China

Introduction: Retinitis pigmentosa (RP) is one of the most severe forms of retinal degeneration, which affects 1 in 3000-3500 individuals. X-linked retinitis pigmentosa (XLRP) is generally early onset and severe form of RP, 70% of XLRP cases are caused by mutation in gene encoding retinitis pigmentosa GTPase regulator (RPGR). Half of patients with mutations in RPGR gene become legally blind at 45 years old yet there is still no effective treatment. The retinal-specific isoform RPGRORF15 localized at photoreceptor connecting cilium involving in modulating cargo trafficking, loss of this protein affects phototransduction proteins in the outer segments (OS). Here we utilized a photoreceptor-targeted gene therapy to restore RPGRORF15 expression and inhibit retinal degeneration with subretinal injection in murine model. **Methods:** The human *RPGRORF15* cDNA was codon-optimized and constructed into pAAV2 vector and driven by a photoreceptor specific promoter hRK (human rhodopsin kinase) and packaged in AAV5 serotype. Dose-dependent expression of RPGRO RF15 was examined in 661W cells and in murine retina by western blot. In vivo cellular localization of human RPGRORF15 at mouse photoreceptor was examined by immunofluorescence with human RPGR specific antibody. The safety study was performed in both C57/BL6 mice and New Zealand White (NZW) rabbits at 1 month and 2 months after subretinal injection of AAV5-hRK-*RPGRORF15* respectively. The function of AAV5-hRK-*RPGRORF15* was tested in RPGR knockout mice. **Results:** RPGRORF15 is highly unstable and prone to lose fragments due to its guanine-adenine rich 3' terminal, we developed and optimized *hRPGRORF15* cDNA with high stability without truncation. Dose-dependent expression of hRPGRORF15 in 661W cells after AAV5-hRK-*hRPGRORF15* transduction was confirmed by western blot, similarly in *in vivo* mouse retina after subretinal injection. The cellular localization of human RPGRORF15 was detected in mouse photoreceptor outer segments by immunofluorescence. Safety study in both C57/BL6 mouse and NZW rabbit show subretinal injection of rAAV-RPGRORF15 was well tolerated *in vivo*, no abnormal retinal structure and inflammatory infiltration were observed. RPGR knockout mice showed gradual thinning of the outer nuclear layer, whereas AAV5-mediated RPGRORF15 expression can alleviate the phenotype. **Conclusion:** Our data provides proof-of-concept to the use of AAV ocular gene therapy for the treatment of XLRP caused by RPGR mutation.

708 Discovery and Characterization of a Safe and Efficacious Gene Replacement Therapy for Treating Bietti Crystalline Dystrophy

Lu Guo[1], Tingting Shen[1], Bin Qu[1], Nan Huang[1], Liang Lu[1], Xi Zhu[1], Wei Li[2], Xiaoping Zhao[1], Shin-Shay Tian[1]

[1]Vitalgen BioPharma, Shanghai, China,[2]Institute of Zoology, Chinese Academy of Sciences, Beijing, China

Bietti Crystalline Dystrophy (BCD, MIM 210370) is an autosomal recessive inherited disease, which was named for its distinguishing yellow-white crystalline deposits observed in patient's fundus. BCD is one of the most prevalent degenerative retinal diseases in East Asia, especially in China, where the frequency is estimated to be 1 in 20,000. *CYP4V2* has been identified as the disease-causing gene of BCD. *CYP4V2* loss-of-function mutation causes a dysregulation of lipid metabolism. BCD patients are characterized by vision loss and night blindness between 20 and 40 years of age and eventual progression to legal blindness between the ages of 50 and 60. Currently, there is no treatment available for BCD. Our laboratory has generated a knockout mouse model of *Cyp4v3*, the homolog of human *CYP4V2* gene. Changes in the ERG a- and b-waves in the *Cyp4v3*$^{-/-}$ mice were observed after 24 weeks of age, with retinal lesions in the fundi of the mice exhibiting ERG changes. The phenotypes of the *Cyp4v3*$^{-/-}$ mice are milder than those of the BCD patients but consistent with the slow natural course of this degenerative eye disease. To evaluate whether *CYP4V2* gene replacement therapy could be beneficial to BCD patients, we generated and evaluated a recombinant scAAV8 to deliver sub-retinally a human *CYP4V2* gene expression cassette. Its efficacy was demonstrated in the *Cyp4v3*$^{-/-}$ mice and published by our group previously (Qu et al., Gene Therapy, 2020, 27(7-8): 370-382). Recently, an improved *CYP4V2* expression cassette was constructed by codon-optimization and promoter screening to generate a *CYP4V2* transgene recombinant AAV named as VGR-R01, which showed significantly increased expression of the CYP4V2 protein in comparison to the previously published construct**.** Pharmacology and toxicology studies were conducted to evaluate the *in vitro* and *in vivo* efficacy, pharmacokinetic, and safety of VGR-R01. *In vitro* cell-based studies showed that VGR-R01 mediated the expression of functional CYP4V2 protein in cell lines and *CYP4V2*$^{-/-}$ iPSC-RPE cells. An *in vivo* proof-of-concept efficacy study was conducted in the *Cyp4v3*$^{-/-}$ mice, and the results showed that ERG amplitudes of both eyes were significantly improved following a single subretinal injection of VGR-R01 in the unilateral eye at a dose of 4.0×10^{7} vg/eye. A safety pharmacology assessment was incorporated into a 13-week GLP-compliant toxicology study in Cynomogous monkeys, and the results showed that VGR-R01 had no effects on cardiovascular or respiratory systems. In the 13-week GLP-compliant toxicology studies in both New Zealand Rabbits and Cynomolgus monkeys, after a single subretinal injection, VGR-R01 was well tolerated in both species and the MTD (maximum tolerate dose) was 1.6×10^{11} and 2.4×10^{12} vg/eye, for rabbits and monkeys (the highest evaluated dose in each species), respectively. No test article related systemic toxicities or T cell immune responses to the capsid or transgene product were observed. Both species developed antibodies to the capsid, but not to the transgene product. Ophthalmic examination and ocular histopathology findings were most likely resulted from the surgery procedure from the subretinal drug adminstration. Following a single administration, VGR-R01 mainly distributed in the ocular tissues, with no obvious changes in the pattern of distribution in the retina over time. In summary, VGR-R01, a safe and efficacious AAV-based gene therapy for treating BCD has been developed. Encouraging results from preliminary investigator-initiated-trials (IITs) have been obtained with Phase I/II trial patient enrollments ongoing in China.

709 A Bi-Cistronic AAV Vector Aimed at Addressing the Complex Pathology Associated with Geographic Atrophy

Peter Widdowson[1], Emily Warner[1], Laura Vaux[1], Kara Boyd[1], Andrew Osborne[1], Katie Binley[2]

[1]Ikarovec, Norwich, United Kingdom,[2]Ikarovec Limited, Norwich, United Kingdom

PurposeStrategies that target components of the complement cascade display variable degrees of success in reducing GA growth and are associated with varying degrees of neovascularisation pathology. Metabolic stress to retinal pigment epithelial (RPE) cells, acting through the NLRP3 inflammasome, is hypothesised to play a pivotal role in this disease. We have developed a bi-cistronic viral vector, IKC159V, capable of enhancing expression of membrane co-factor protein (MCP/CD46) and pigment epithelium-derived factor (PEDF) which are both reduced in individuals with GA. As PEDF has anti-angiogenic, retinoprotective, and anti-inflammatory properties, loss of this protein reduces the ability of the RPE to withstand oxidative stress. Loss of endogenous CD46 leaves the retina highly susceptible to complement attack. We report on the *in vivo* efficacy of IKC159V which aims to provide greater efficacy against GA than sole anti-complement approaches. **Methods**IKC159V was evaluated in multiple rodent GA models. Transgene protein expression levels were examined by retinal immunohistochemistry and vitreal ELISA or Western blot after intravitreal or subretinal delivery. Efficacy was evaluated via fluorescein angiography (FA) and choroidal flat-mount analysis 7 days post laser CNV. Functional activity of soluble CD46 (sCD46) was determined through vitreal C3b cleavage assays and PEDF retino-protection was demonstrated 7-days after intravitreal NMDA induced toxicity or 2-days after intravenous sodium iodate (SI) treatment. **Results**Functional activity of sCD46 expressed from the IKC159V vector resulted in significantly more cleavage of C3b to iC3b (IKC159V = 47%, Null = 8% P<0.001) and was as efficacious as a vector expressing CFI only (CFI = 59%). The SI model specifically causes oxidative damage and degeneration of RPE and PRs that model GA pathology. IKC159V was able to show significant RPE sparing following systemic SI measured 2 days later (IKC159V = 44% RPE loss, Null = 71%, p<0.001). In the laser CNV model, IKC159V reduced the proportion of leaky lesions compared to Null vector (IKC159V = 52%, Null = 76%, P<0.001) and attenuated the neovascular area (IKC159V = 8782 ± 1870 pixels, Null = 17403 ± 4520 pixels; P = 0.08). Finally, elevated PEDF levels correlated with retinal ganglion cell neuroprotection from 30nmol NMDA insult (IKC159V = 780 cells, Null = 358 cells P<0.001).**Conclusion**IKC159V leads to expression of functional sCD46 and PEDF that show a reduction in the activation of the complement cascade and protection of retinal cells respectively. Our data suggests that expression of PEDF in combination with sCD46 may slow GA progression and reduce VEGF-induced leakage in addition to neovascularisation. These data support the therapeutic potential of IKC159V for the treatment of GA.

710 Intraocular and Systemic Gene Therapy for Gyrate Atrophy of the Choroid and Retina

Fabio Dell'Aquila[1], Roberto Di Cunto[1], Iolanda Boffa[1], Elena Marrocco[1], Simone Notaro[1], Nicola Brunetti-Pierri[1,2], Alberto Auricchio[1,3]

[1]Molecular Therapy, TIGEM, Pozzuoli, Italy,[2]Department of Translational Medicine, University of Naples Federico II, Naples, Italy,[3]Scuola Superiore Meridionale "SSM", University of Naples "Federico II", Naples, Italy

Gyrate atrophy of the choroid and retina (GACR) is due to ornithine aminotransferase (*OAT*) deficiency which causes hyperornithinaemia leading to retinal pigment epithelium (RPE) toxicity and impaired vision. Adeno-associated viral (AAV) vector-mediated *OAT* liver gene transfer lowers ornithinaemia in the *Oat*$^{-/-}$ mouse model of GACR and protects retinal structure and function but without full normalization. We investigated whether restoration of retinal OAT expression improves the retinal phenotype of *Oat*$^{-/-}$ mice. A single subretinal administration of an AAV vector encoding human OAT (AAV-*OAT*) results in intraocular OAT expression, reduced RPE abnormalities and improved thickness of the outer nuclear layer in *Oat*$^{-/-}$ mice up to 12 months of age. However, retinal electrical activity remained reduced, suggesting that hyperornithinaemia, which is not decreased by subretinal AAV delivery, impairs retinal function. We are currently testing if the combination of retinal and liver Oat gene transfer provides higher therapeutic benefit than each of the two separate approaches.

711 Engineered Melanopsin Mutants for Optogenetic Vision Restoration

Cameron K. Baker, Patrick Cervantes, Jodie Jacobs, Morgan Burke, Alex Tai, Ali Aghajanirefah, Andy Phung, Jie Ma, Ruslan N. Grishanin, Gustavo de Alencastro, Brigit E. Riley

Adverum Biotechnologies, Redwood City, CA

There are limited treatment options for blindness caused by the irreversible death of photoreceptors. Without photosensitive cells, the retina cannot send light information to the brain. One strategy to restore light perception in these patients is through optogenetics, where DNA for a light sensitive protein is delivered to the remaining retinal cells, essentially making new pseudo-photoreceptors. Visual resolution is proportional to the number of pseudo-photoreceptors created, so an AAV capable of achieving pan retinal expression through intravitreal injection, like AAV2.7m8, is potentially most advantageous. Previous work in optogenetic vision restoration has demonstrated that both light sensitive ion channels (channelrhodopsins like ChR2 and ChrimsonR) and G-protein-coupled receptor (GPCR) opsins like rhodopsin and the cone opsins have strengths and weakness, and as such, neither are ideal as light sensors. For example, cells expressing channelrhodopsins are much less light sensitive than those with rhodopsin or the cone opsins. These channelrhdopsins are so light insensitive that medical devices such as light amplifying goggles and implantable LED arrays are often required to generate sufficient light for a visual response. Besides being sensitive to ambient light, GPCR opsins can also adapt to light making their overall range of light sensitivity much greater than that of their ion channel counterparts. However, rhodopsin and the cone opsins, when expressed outside of photoreceptors, are extremely slow at responding to the removal of light, reducing visual acuity. In contrast, the channelrhodopsins respond more quickly to light withdrawal and can also more easily source and regenerate their own light sensitive chemical, retinal. Rhodopsin and the cone opsins rely on specific processes supplied by retinal pigmented epithelial (RPE) cells to regenerate retinal that are difficult to impossible to recapitulate when expressed outside of non-photoreceptor cells. The inability to source or regenerate retinal could impair the ability to respond to light over time. Potentially a better light sensor candidate to generate pseudo-photoreceptors for optogenetic vision restoration is melanopsin, the light sensor for circadian rhythm and pupil dilation, which has both the light sensitivity of rhodopsin and the cone opsins as well as the ability to source and regenerate retinal. However, its extremely slow kinetics prevents it from being the ideal light sensor for optogenetic vision restoration. To improve the kinetics of melanopsin, close to one hundred mutants were developed and screened through *in vitro* fluorescent calcium imaging. Mutations to phosphorylation sites, particularly on the c-terminus (CTD), which becomes more likely to bind to signal terminating beta arrestins after phosphorylation, showed improved kinetics over wildtype. Other mutational strategies targeting signal termination and beta arrestin binding through truncation of the CTD as well as substituting it for the CTD of other GPCRs also yielded mutants with faster light response termination. The improved kinetics in these engineered melanopsin mutants suggests they could be utilized as a therapeutic transgene for optogenetic vision restoration.

712 Compact CRISPR/Cas12-Based Mutation Independent Therapy Strategy for Rhodopsin-Associated Autosomal Dominant Retinitis Pigmentosa via Single AAVs

Luyao Li[1], Xiangfeng Kong[1], Jinhui Li[1], Guixiang Yang[1], Yuqin Yao[1], Weizhi Liu[1], Lingqiong Cai[1], Jianlong Chen[1], Xing Wang[1], Shaoran Wang[1], Linyu Shi[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Retinitis Pigmentosa (RP), a group of inherited, retinal degenerative diseases resulting in vision loss and blindness, is the most common inherited retinal disease, affecting 1 in 3000-7000 individuals. Mutations in over 60 known genes have been found to be causative factors of RP, among which mutations in the rhodopsin (*RHO*) gene are the most common cause and are associated with 25%~35% of autosomal dominantly inherited RP (adRP), affecting 7,500 patients in US and 12,100 patients in EU and UK. More than 150 different mutations in the *RHO* gene have been identified to cause RHO-adRP with progressive loss of rods followed by loss of cones and the apoptosis of the photoreceptor cell, resulting in the loss of the visual function. Currently, there are no curative therapy for RHO-adRP. Here we developed a gene editing based therapy strategy to knockout the endogenous *RHO* gene independent of the mutations via proprietary compact CRISPR/Cas12 system then introduce a normal exogenous copy to maintain the rod normal function via single AAVs - a "knockout and replace" therapy to treat RHO-adRP. **Methods**: We constructed a humanized RHO mouse model, with part of the mouse *Rho* gene

sequence replaced with human *RHO* gene sequence. An all-in-one AAV vector, comprising a rod-specific promoter fragment, a miniature CRISPR-Cas12 system and an optimized exogenous human *RHO* cDNA fragment (exo-RHO) with the highest expression efficiency (Cas12-hRHO), was constructed to develop a therapeutic strategy that rescues the visual function by knocking out the endogenous *RHO* gene (endo-RHO) independent of the mutations and supplementing with an exogenous human *RHO* copy. 6-week-old humanized RHO mice were subretinally injected with AAVs. We further tested this approach in human retinal explants and the cynomolgus monkey retina. **Results:** In the humanized RHO mice, Cas12-hRHO efficiently edited the endo-RHO, resulting in ~70% mRNA knockdown. Furthermore, the exo-RHO mRNA was successfully expressed to ~50% of the normal level (Figure 1A). Similar results were also observed in human retinal explants infected with Cas12-hRHO. Moreover, efficiency of Cas12-hRHO was tested in the cynomolgus monkey retina by subretinal injection (Figure 1B). Although our gRNAs had mismatches with the cynomolgus monkey genome, we still observed approximately 20% editing efficiency. The amount of endogenous *RHO* transcripts decreased by nearly 70%, and the amount of exogenous *RHO* transcripts was approximately 150% that of the endogenous controls. **Conclusions**: Our study provides an alternative CRISPR/Cas12-based treatment for RHO-adRP. Further demonstration of *in vivo* treatment effects using the disease mouse model will verify the potential of Cas12-hRHO as a therapeutic strategy for RHO-adRP with the potential to treat any of the over 150 dominant gain-of-function mutations with a single injection.

713 Restoration of Retinal Function and Structure in an *Rpe65*-Deficient Murine Model via Gene Replacement Therapy

Weiwei Wu[1], Sheng He[1], Qi Yang[1], Chenhua Yang[1], Jingyu Zhang[1], Jipeng Song[1], Mengke Zhu[1], Linyu Shi[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Mutations in *RPE65* block the visual cycle, resulting in a congenitally inadequate supply of chromophore to both rod- and cone-photoreceptors. The *RPE65*-mediated inherited retinal dystrophy (IRD) spectrum therefore exhibits common clinical findings, initially characterized by night blindness that begins in early childhood followed by progressive degeneration of retinal structure and function. Here, we reported HG004, a novel investigational AAV based-gene therapy drug, for the treatment of *RPE65*-IRD and evaluated its efficacy in a *Rpe65*-deficient murine model. **Methods:** We independently-developed a *Rpe65*-deficient murine model by proprietary CRISPR genome-editing system. These animals (1 to 2-month-old or 10-month-old) were randomized into groups and administrated with either HG004 or vehicle by a single subretinal injection. Efficacy was evaluated by retinal optical coherence tomography (OCT), electroretinography (ERG), and histochemical staining. **Results:** Scotopic b-wave responses in all treated groups were significantly recovered at all time points, compared with vehicle-injected control eyes of *Rpe65*$^{-/-}$ mice ($p<0.01$) after the injection of HG004 (Fig. 1a). The restoration ratio at 3×10^8 vg/eye was over 60% of the wildtype (WT) level, and the durability of the therapeutic effect maintains for at least 34 weeks (Fig. 1a). At week 35 post-injection, the retinal thickness of *Rpe65*$^{-/-}$ mice treated with HG004 at 3×10^8 vg/eye could be maintained at about 85% of the WT level (Fig. 1b), compared with the untreated eyes (67% of the WT level). Furthermore, at week 15 post-injection of HG004 at 6×10^8 vg/eye, the ERG amplitude of the treated eyes in 10-month-old *Rpe65*$^{-/-}$ mice could recover to 38.7% of WT mice at the same age (Fig. 1c). The retinal thickness of these eyes could be maintained at about 62% of the WT level, while the untreated eyes were only 53%. In contrary to the abnormalities in the retinal structure of untreated *Rpe65* deficient mice, the photoreceptor cells of the treated eyes were neatly arranged, and the OS density was consistent with that of the WT animals at week 16. **Conclusions:** Our findings demonstrated that HG004 could significantly restore the function of RPE cells and photoreceptor cells and maintain the integrity of retinal structure in *Rpe65*$^{-/-}$ mice. Furthermore, the durability of the therapeutic effect was sustained for at least 34 weeks. Although the retina of 10-month-old *Rpe65*$^{-/-}$ mice had shown irreversible photoreceptor cell degeneration, the treatment of HG004 could still restore the functions of the remaining photoreceptor cells and RPE cells, resulting in the prevention of the retinal outer segment disc disorder and further degeneration of the photoreceptor cells. These results strongly support the hypothesis that HG004 may provide benefits to *RPE65*-IRD patients. Importantly, our data generated by *Rpe65*-deficient murine model support the recent HG004 IND clearance by US FDA.

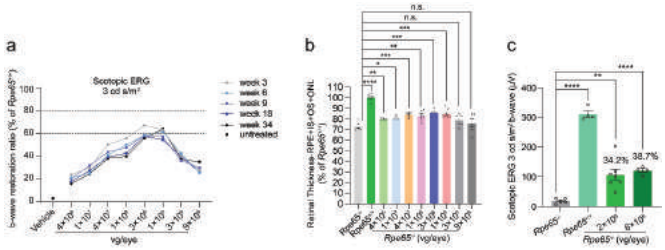

Figure 1. Efficacy of HG004 in *Rep65*-deficient murine model

714 COMET-Mediated Delivery of C^{3}DNA in Human Cell-Based *In Vitro* Models of Retinal Pigment Epithelium

Rachelle Prantil-Baun[1], Rosario Fernandez-Godino[1], Nathan Sorensen[1], Stefania Lenna[1], Pranal Dakle[1], Ricardo Saldana-Meyer[2], Jaka Cemazar[1], Gayathri Ramaswamy[3]

[1]Drug Discovery and Disease Biology, Intergalactic Therapeutics, Inc., Cambridge, MA,[2]Molecular Design, Intergalactic Therapeutics, Inc., Cambridge, MA,[3]Drug Discovery and Disease Biology, Intergalactic Therapeutics, Cambridge, MA

Introduction Inherited retinal diseases, such as Stargardt disease (STDG1), are a large group of genetically and clinically heterogeneous conditions which lead to blindness. Stargardt disease (*ABCA4*- related) is the most common form of juvenile macular dystrophy characterized by the accumulation of lipid-rich deposits (also known as lipofuscin) in the retinal pigment epithelium (RPE), RPE atrophy, and photoreceptor cell death. It was shown recently that lack of *ABCA4* function disrupts lipid homeostasis in the RPE cells leading to lipofuscin formation, which is a hallmark of STDG1. STDG1 is autosomal recessive and polymorphic with > 900 known mutations in the human *ABCA4* gene. Delivery of full-length wild type copy of human *ABCA4* gene may provide an ability to treat the spectrum of *ABCA4*-related retinopathies in a mutation agnostic manner. However, the large size of the wild type human *ABCA4* gene makes its delivery unamenable to AAV mediated delivery. Intergalactic's proprietary non-viral C^{3}DNA (covalently closed circular DNA) allows for the design and delivery of DNA payload beyond the size limitation of canonical viral cargo. Additionally, Intergalactic's proprietary electro-transfer system, COMET, enables the local delivery of genes to the relevant cell type. To assess the functional effect of delivery of full length *ABCA4* to the retinal cells in vitro, it is important to establish a relevant cellular model system. The *Abca4* knock-out mouse model shows lipofuscin accumulation in the RPE. To recapitulate the human RPE dysfunction phenotype, we generated a CRISPR knockout of the *ABCA4* gene in human inducible pluripotent stem cells (IPSCs) and differentiated them to RPE cells (iRPE). Our goal was to utilize the iRPE cells that were null for *ABCA4* to investigate the effect of COMET-mediated delivery of C^{3}DNA expressing full length, wildtype ABCA4 protein on RPE function. **Methods** Wild type (WT) iRPE cells were derived from a commercially available IPSC cell line using previously reported methods. CRISPR gene editing was used to generate an *ABCA4* knock-out (*ABCA4* KO) iRPE cell line that was null for *ABCA4*. Both WT and *ABCA4* KO cell lines were confirmed to be differentiated RPE cells using flow cytometric analyses for progenitor markers, PAX6 and MiTF, and mature RPE markers, BEST1 and RPE65. Additionally, the two cell lines were assessed for RPE function based on their ability to phagocytose labeled photoreceptor outer segments. WT and ABCA4 knock out iRPE cell lines were transfected with C3DNA expressing full length human *ABCA4* gene using COMET. Post-transfection, both WT and ABCA KO iRPE cultures were assessed for transepithelial electrical resistance (TEER), phagocytosis, protein expression of ABCA4, and lipid dysregulation. **Results and Discussion** There was no difference between wild type and *ABCA4* KO cells in barrier function with TEER and phagocytic uptake of FITC-labeled photoreceptor outer segments. Assessment of lipid dysregulation in *ABCA4* KO cells showed an increased intracellular accumulation of cholesterol as indicated by filipin staining and a significant increase in neutral lipid formation, indicated by BODIPY staining. These data suggest that *ABCA4* may have a role in lipofuscin formation, which is rich in lipids. Based on the above results, *ABCA4* KO RPE cell line could serve as an appropriate in vitro model system to assess the effect of COMET-mediated delivery of C^{3}DNA expressing full length, wildtype *ABCA4* protein on RPE function.

715 *In Vivo* Production of Full-Length ABCA4 Protein Following Cre-Mediated Recombination from Dual AAV Vectors in ABCA4$^{-/-}$ Mice

Olga Kourennaia, Joseph Fogerty, Rachel M. Stupay, Alyna Cascone, Linas Padegimas, Paul T. Wille, Brian M. Kevany

Product Development, Abeona Therapeutics, Cleveland, OH

Autosomal recessive Stargardt disease is caused by mutations in the retina-specific ABCA4 gene. Decreased central vision due to loss of photoreceptors in the macula and increased fundus autofluorescence are hallmarks of the disease. Due to the limited packaging capacity of AAV vectors, the 6.8 kilobase human ABCA4 open reading frame cannot be packaged into a single viral particle. As an alternative, we developed a dual vector strategy that uses a Cre-mediated recombination between two partial sequences to produce full-length hABCA4. We were able to express full-length hABCA4 protein both in vitro via viral transduction of HEK293 cells and in vivo in photoreceptor cells after subretinal dual AAV injection into ABCA4$^{-/-}$ mouse eyes. We confirmed fidelity of Cre-mediated recombination of ABCA4 by sequencing the transgenic RNA from transfected HEK293 cells as well as from AAV-dosed animals. Immunohistochemistry results confirmed correct localization of recombinant hABCA4 protein into photoreceptor outer segments of dosed animals. Our results showed that Cre-mediated recombination of dual AAV vectors was safe and effective in delivery and expression of full-length ABCA4 in a knockout mouse model, paving the way for a novel therapeutic approach for treating Stargardt disease that could be used as a universal approach for multipartite large gene delivery.

716 ELOVL2 Gene Therapy: Photoreceptor Lipid Restoring Strategy to Treat Dry Age-Related Macular Degeneration (AMD)

Christopher L. Chavez, Martin Emanuele

Visgenx, Santa Cruz, CA

Dry age-related macular degeneration (dry AMD) is a slowly progressing debilitating retinal disease which leads to the loss of macular cone photoreceptors. It is the third leading cause of blindness in the world with a prevalence similar to that of cancer and more than twice that of Alzheimer's. People with advanced stages of dry AMD struggle with everyday tasks such as reading and facial recognition. Currently there are no approved treatments. Elongation of very-long-chain fatty acids-like 2 (ELOVL2) enzyme is the rate limiting elongase involved in the elongation of long-chain (C22->C24) polyunsaturated fatty acids (LC-PUFAs). ELOVL2 is involved in the production of docosahexaenoic acid (DHA) 22:6n-3 as well as very-long-chain PUFAs (VLC-PUFAs). DHA is the most abundant polyunsaturated fatty acid

(FA) in mammals, constitutes approximately 35% of total FAs in the retina and is the most abundant FA in rod outer segments (50-70% of FAs). Within photoreceptor outer segment disk membranes, these LC-PUFAs provide a crucial and specialized environment for the proper functioning of opsins in the visual pathway. Knockout of ELOVL2 in mice, results in a phenotype similar to AMD; diminished ERG, drusen formation and complement accumulation within the retina of young mice. As mice age, the ELOVL2 promoter becomes increasingly methylated resulting in decreased ELOVL2 expression. In humans, a CpG island within the promoter of ELOVL2 becomes progressively methylated with age and is one of the most robust biomarkers of age. Diminishing ELOVL2 expression and the concomitant decline in DHA and VLC-PUFA production associated with aging, we believe is a major factor underlying susceptibility to AMD. To test this, we designed and constructed a series of optimized ELOVL2 expression cassettes as candidate therapeutics for dry AMD related vision loss and we pursued both viral and non-viral approaches. One-year old C57BL/6J mice were treated with a single subretinal AAV8-optELOVL2 administration or with saline vehicle in the contralateral eye and followed for six months. Compared to vehicle, treated eyes were protected against aging related loss of vision as evidenced by: 1) ERG a and b waves of greater magnitude and shorter latency and 2) reduced thinning of the outer retina photoreceptor layer (a hallmark of dry-AMD) as measured by OCT. Efficacy at higher dosages was limited by toxicity which we believe to be promoter related. Second-generation viral constructs which are high expressing and better tolerated were also tested and provided protection from thinning of the outer retina photoreceptor layer in mice. The results from a non-human primate study using AAV-ELOVL2 are currently being collected and analyzed and will be presented. To overcome some of the limitations of AAV as a delivery vehicle, a novel method for creating DNA constructs with payloads of any size is being developed. These synthetic constructs have been delivered non-virally using lipid nanoparticles and have demonstrated strong and durable expression *in vitro*. The results from a planned mouse study will be presented to further evaluate the efficacy of this new method.

717 Best Time for Adeno-Associated Virus (AAV) Neutralizing Antibody (NAb) Prescreening of NHPs Prior to Gene Therapy Studies

Rajeev K. Dhawan, Connor Balzer, Lachelle Campbell, Brittany Egan, Donald Nicholson

Charles River Laboratories, Wilmington, MA

Following recent approval of AAV based drugs by FDA, a huge increase in the number of gene therapy trials employing AAV based viral vectors has been observed. Efficacy of AAV drugs can be compromised by the presence of neutralizing antibodies (NAb) in both humans and NHPs as a result of immune responses to previous exposures to AAV. Therefore, it's very important to prescreen NHPs prior to selection for gene therapy studies as NAbs may interfere with the biodistribution of the AAV drugs, potentially impacting the outcome of clinical trials. Prescreening of NHPs is routinely performed at the vendor site or during quarantine at the study site; however, determining how far in advance to test these NHPs to avoid seroconversion between testing and the start of a study remains an important question. To begin to answer this question, we performed two separate studies tracking seroconversion in NHPs. In the first study, 100 cynomolgus macaques were sourced from a single Asian supplier. They were housed in separate rooms and occasionally were grouped with cohorts from other suppliers. Sera was collected from NHPs at 0, 4 and 7 months post arrival. The sera samples from 20 NHPs, 12 males and 8 females, were tested by AAV2, AAV8, AAV9 and AAVrh74 NAb screening assays at sample dilutions of 1/10, 1/20 and 1/40. While the majority of NHPs showed no significant change in AAV NAb titer over the course of the study, a small number of animals showed an increase in NAb titer greater than 4-fold in 4-7 months. In a second study, 300 male and 300 female cynos from a single supplier were screened on arrival (week 0) with 76 of them negative for AAV8 NAbs. Another round of AAV8 NAb screening was performed at week 8 with 13/76 sera showing seroconversion. Additionally, these 13 seroconverted NHPs (week 0 vs 8) were screened by AAV2 and AAV9 NAb assays showing a reduced rate of seroconversion for these two serotypes indicating seroconversion for different serotypes was not similar in individual NHPs. Both studies confirmed seroconversion occurs in NHPs with time. This suggests that, in addition to prescreening, a second round of confirmatory screening is highly recommended, preferably within a month prior to beginning gene therapy studies.

718 Neutralizing Antibody Seroprevalence of Six Adeno-Associated Virus Serotypes Relevant to Gene Therapy in the United States

John E. J. Rasko[1], George Bashirians[2], Christos Petropoulos[3], Terri Wrin[3], Suryanarayan Somanathan[2], Yuvika Paliwal[4], Peter V. Henstock[5], Candida da Fonseca Pereira[6], Priya Patel[7], Ian Winburn[8], Amit Chhabra[7]

[1]Gene and Stem Cell Therapy Program, Centenary Institute, and Faculty of Medicine and Health, The University of Sydney, Camperdown, Australia; Royal Prince Alfred Hospital, Sydney, Australia,[2]Pfizer Inc, Cambridge, MA,[3]Labcorp-Monogram, South San Francisco, CA,[4]Pfizer Inc, Collegeville, PA,[5]Pfizer Inc, Andover, MA,[6]Pfizer Australia, Sydney, Australia,[7]Pfizer Inc., New York City, NY,[8]Pfizer Ltd., Walton on the Hill, United Kingdom

Introduction: Adeno-associated virus (AAV) mediated gene therapy for several indications have been approved, although pre-existing neutralizing antibodies (NAbs) against AAV serotypes can interfere with efficacy. This subset analysis of an international, noninterventional, observational, retrospective, cross sectional study focused on the NAb prevalence of 6 AAV serotypes in individuals aged ≥16 and <16 from the United States. Methods: Serum samples from the Pfizer Biobank were obtained from participants that were enrolled in previous non-gene therapy clinical studies conducted between 2015 and 2019. Matching participant-level data on demographics and clinical characteristics were obtained from each clinical trial database. NAb seroprevalence for 6 AAV serotypes (AAV1, AAV5, AAV6, AAV8, AAV9, AAVRh74var[AAV-Spark100]) was estimated at a range of dilutions (from 1:1 to 1:50,000), and NAb titer levels were determined using anti-AAV NAb assays based on cell transduction inhibition (ID50). Results: There were 50 samples from patients ≥16 years of age. At 1:1 dilution, NAb prevalence was lowest for AAV9 (48%) and AAVRh74var [Spark 100] (48%); 86% for AAV1, 68% for AAV5, 66%

for AAV6, 50% for AAV8. At 1:2 serum dilution, NAbs against AAV1 and AAV6 were the most prevalent (48% and 54%, respectively). At 1:2 and subsequent dilutions, AAV5 had the lowest seroprevalence among the AAV serotypes. At 1:4 serum dilution, NAbs against AAV5 (18%) and AAVRh74var (34%) presented the least prevalence, while NAbs against AAV1 remained the most prevalent. At 1:2,000, 1:10,000, and 1:50,000 dilutions all NAbs against the 6 AAVs were undetectable. There were 31 samples from patients <16 years of age. At 1:1 dilution, NAb prevalence was lowest for AAV8 (39%) and AAV9 (39%); 68% for AAV1, 55% for AAV5, 52% for AAV6, 42% for AAVRh74var. At 1:2 serum dilution, NAbs against AAV1 (42%) was the most prevalent and least prevalent for AAV5 (26%). Similar to adults, at 1:2,000, 1:10,000, and 1:50,000 dilutions all NAbs against the 6 AAVs were undetectable. Conclusions: The seroprevalence of NAbs against 6 different AAV serotypes in the US was determined using a robust cell transduction inhibition assay. Overall, children exhibited lower seroprevalence compared with adult samples, consistent with natural environmental exposure. Our results indicate variation within the US across different AAVs, with implications for clinical gene therapies.

719 Optimized CRISPR Engineering of the IgH Locus in Non-Human Primate Hematopoietic Cells for Induced Humoral Immunity

Jack M. P. Castelli[1,2], Rachel A. Cunningham[1,2], Molly E. Cassidy[1], Katrina Poljakov[3], Matthew D. Gray[3], Mark R. Enstrom[1], Justin J. Taylor[3,4], Jennifer E. Adair[1,2]

[1]Translational Science and Therapeutics Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA,[3]Vaccine and Infectious Diseases Division, Fred Hutchinson Cancer Center, Seattle, WA,[4]Department of Immunology, University of Washington, Seattle, WA

B cell editing has enabled expression of engineered antibodies conferring anti-viral protection in murine models. CRISPR/Cas systems can target the immunoglobulin heavy chain (*IgH*) locus, replacing endogenous antibodies with transgenes delivered by viral vectors[1]. While this approach could replace repeated antibody infusions, it remains unclear how long a gene edited B cell immune response can last. A potential solution is engineering hematopoietic stem and progenitor cells (HSPC), precursors to all B cells. A large-animal model such as non-human primates (NHP) could permit more clinically relevant, autologous studies with infectious challenge. Here, we evaluated editing to introduce transgenic sequences at the *IgH* locus of NHP. We isolated HSPC and sequenced the *IgH* locus from two different species, *Macaca mulatta* and *Macaca nemestrina*, to design optimal CRISPR components. We observed 99.2% identity between the two species and 84.2% identity to human sequences in the *IgH* constant region. To identify optimal CRISPR guide RNAs, sequences predicted to result in ≥3 bp deletions were selected as preferential for homology-directed repair (HDR) outcomes[2]. A total of 10 RNA guides out of hundreds were synthesized for testing, n=5 each for Cas9 and Cas12a. We purified CD34$^+$ HSPC using immunomagnetic separation on whole bone marrow aspirate from healthy donor animals (n=2). HSPC were electroporated using equal ribonucleoprotein concentrations for each nuclease. Next-generation sequencing demonstrated higher indel frequencies with Cas12a than Cas9, with editing rates up to 2.3% when accounting for background mutations and a targeted quantification window (Fig.a). Indel types observed for Cas12a aligned with higher likelihood of HDR events. To test this, a DNA template (JMPC01) encoding a GFP reporter was used to evaluate HDR at the optimal Cas12a target site. This template was co-delivered with Cas12a via electroporation in an NHP B cell line (LCL 8664) as plasmid DNA, double-stranded DNA (dsDNA), and end-biotinylated dsDNA (Bio5P dsDNA), resulting in 1.0%, 2.6%, and 1.9% GFP+ cells at day +10, respectively (Fig.b). We are now applying this editing strategy in primary NHP HSPC to assess engraftment and differentiation into B cells in the MISTRG mouse strain. Based on experience in primatized MISTRG mice, B cell progeny will be evaluable in the next month. Further studies in pre-clinical NHP models will assess the safety and efficiency of this approach for achieving long-term humoral immunity in diseases for which there are no vaccines.

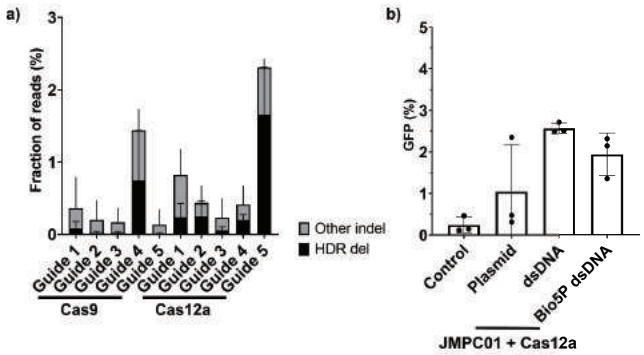

Figure. a) Frequency of indels and HDR-like deletions (HDR del ≥3 bp deletions) at the cut site in HSPC. b) GFP expression in LCL 8664 at day +10, comparing JMPC01 with Cas12a to control without nuclease.

720 Genetic Vaccine Induced T Cells Can Partially Control SARS-CoV-2 Replication

Gustaf Ahlén[1], Jinyi Yan[1], Sofia Appelberg[2], Lars Frelin[3], Ali Mirazimi[1], Matti Sallberg[1]

[1]Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden,[2]Folkhälsomyndigheten, Stockholm, Sweden,[3]Karolinska Institutet, Stockholm, Sweden

Vaccine or infection induced SARS-CoV-2-specific neutralizing antibodies (NAbs) show a poor cross reactivity between SARS-CoV species and SARS-CoV-2 variants and often fail to protect against infection. However, protection against severe disease and death suggests a protective role for cross-reactive T cells. To better understand the role of Nabs and T cells, we generated genetic and protein vaccines containing the complete spike, the receptor binding domain (RBD), the membrane (M) and/or nucleoprotein (N) that induced only T cells, or both NAbs and T cells. In three challenge models with homologous or heterologous challenge, high levels of vaccine induced SARS-CoV-2 NAbs did not protect against infection or histological signs of disease but conferred a rapid viral control and a mild limited histological damage. In the absence or low levels of cross-reactive NAbs, vaccine-

primed T cells were able to partially control viral replication to promote a NAb recall-responses. T cells alone did not protect against histological damage, most likely due to more extensive viral spread the absence of NAbs, and instead a partial control mediated by the elimination of infected cells by T cells. Overall, vaccine or infection induced Nabs will most likely never confer a long-term sterile immunity against SARS-CoV-2, as has become evident from real life studies. More realistically, multi component SARS-CoV vaccines should strive for both broadly cross-reactive NAbs and T cells. Importantly, cross-reactive T cells primed by multi component vaccines and/or natural infection, may offer a long term protection against severe disease and death during the current and future pandemics.

721 Extreme Inter-Individual Variability of Subretinal AAV-Induced Immune Response Even in a Highly Standardized Context

Duohao Ren[1,2], Audrey Pineiro[1], Gaelle Chaveau[1,2], Julie Vendomele[1], Divya Ail[2], Deniz Dalkara[2], Giuseppe Ronzitti[1], Anne Galy[1], Sylvain Fisson[1,2]

[1]GENETHON, INSERM, Evry/Paris-Saclay University, Evry, France,[2]Institut de la Vision, INSERM, Paris, France

Introduction. Ocular gene therapies that use adeno-associated viruses (AAVs) to deliver genes have been successfully applied in some inherited retinal diseases. However, inflammation resulting from immune responses to the AAV or the transgene remains an important concern. Anti-transgene and anti-capsid immune responses has been reported in some patients who received AAV gene therapy, which adversely can affect safety and efficiency of the therapy. At present, immunomonitoring and finding pertinent biomarkers are crucial challenges for patient management. Heterogeneity in the strength of the immune response between patients is traditionally thought to be the consequence of genetic background diversity and previous exposure to different pathogens. In a syngeneic murine model, we have previously reported that a single subretinal injection of AAV8 induces a systematic anti-transgene T-cell response, but with with different levels of intensity. Here, we analysed complementary innate and adaptive immune components to have a better understanding of the immune consequences subsequent to a subretinal AAV injection and the degree of individual diversity in a standardized context. Methods. Transgene cassette encoding the HY male antigen, containing MHC class I- and MHC class IIrestricted T-cell epitopes, immunodominant in female H-2b background, was packaged into AAV8 under the ubiquitous PGK promoter. Several experiments were done with a single subretinal injection of high dose AAV8-HY was performed at day 0 in immunocompetent adult female wild type C57BL/6 (H-2b) mice. At day 21, RT-droplet digital PCR (ddPCR), ELISpot, in vivo cytotoxicity and ELISA were done to evaluate the transgene expression, antigen presenting cell markers, T-cell responses and antibody production. Principle component analysis, correlations, and diversity index have been calculated based on the data from each readout. Results. Surprisingly, we found a very strong variability of the immune response between mice of the experiments, despite a steady local and systemic immune reactivity following the subretinal injection of AAV8-HY. Indeed, none of the mice display the same immune response profile albeit the identical genetic background, injected product, housing conditions, and surgery being performed by the same individual. Conclusions. We provide experimental evidence on the extreme inter-individual variability of local and systemic immune responses following a subretinal AAV injection on syngeneic mice and in a highly standardized context. This suggests that in patients subjected to ocular gene therapy, in addition to variable genetic backgrounds and different immune history, immunomonitoring should take into account that inter-individual immune responses are basically very heterogeneous, and no individual immunological parameter can predict the evolution of the immune response behaviour alone.

722 Enabling *In Vivo* Therapeutic Antibody Production through Hematopoietic B Cell Engineering

Anne-Sophie Kuhlmann[1], Nawal Madkhali[1], Eliana Moskovitz[1], Jacob E. Parrott[1], Sowmya Reddy[1], Rasika Venkataraman[1], Matthew D. Gray[2], Justin J. Taylor[2], Christopher W. Peterson[1], Hans-Peter Kiem[1]

[1]Stem Cell and Gene Therapy Program, Clinical Research Division, Fred Hutchinson Cancer Center, Seattle, WA,[2]Vaccine and Infectious Disease Division, Fred Hutchinson Cancer Center, Seattle, WA

Persistent therapeutic protein production has tremendous potential for a myriad of malignant, genetic and infectious diseases. B cells are among the most proficient protein-secreting cell types in the body and are highly specialized for expression of antibodies. Recent studies demonstrate that *ex vivo* and *in vivo* gene-edited human and murine B cells can efficiently produce therapeutic proteins, including antibodies. However, few studies have explored this approach in immunocompetent large animal models, which most closely model and predict therapeutic potential in patients. Therefore, we have been developing a nonhuman primate (NHP) model of B cell gene therapy to assess the function and persistence of engineered B cells *in vivo*. Considering our longstanding experience with persistent HIV-1 acquisition in the NHP model, our experiments have focused on the reprogramming of distinct hematopoietic cell types with HIV-specific broadly neutralizing antibodies (bNAbs). NHP hematopoietic stem and progenitor cells (HSPCs) and B cells were modified *ex vivo* with bNAb-encoding lentiviral vectors (LV) or CRISPR-Cas9/AAV6 donors, respectively. Both LV and AAV6 donors encoded VRC01, an anti-HIV bNAb that has been extensively investigated in clinical studies. AAV6-VRC01 donors were targeted to the endogenous immunoglobulin heavy chain (IGH) locus. PCR- and flow cytometry-based methods were used to quantify gene-modified cell products *ex vivo* and their persistence *in vivo*, while antibody production was assessed by ELISA. A pilot experiment focused on autologous transplantation of VRC01 bNAb LV-modified HSPCs. Although modified cells and VRC01 mRNA expression persisted, secreted VRC01 antibody was detected at low concentrations in the blood before declining to undetectable levels 2 months post-transplant. Anti-drug antibodies (ADA) directed against the exogenously expressed proteins were also detected. Considering these results, we then investigated B cell editing as an alternative approach to augment bNAb expression and persistence while decreasing immunogenicity issues in the NHP model. The editing approach demonstrated an MMEJ:NHEJ ratio associated with efficient HDR and resulted in 80-90% indels efficiency. Integration of the VRC01 donor at the targeted IGH locus was confirmed by in-out PCR. Up to 15% of the B cells expressed VRC01 bNAb at the

cell surface as detected by flow cytometry 5 to 8 days post-editing. Our data demonstrate efficient macaque B cell engineering for anti-HIV bNAb production and lay the foundation for the evaluation of this approach in our immunocompetent NHP model. Targeted modification of the IGH locus in B cells provides many advantages over lentivirus modifications or repeated antibody injections such as acquisition of tolerance, non-immunogenic glycosylation pattern, antigen-inducible protein production, affinity maturation and antibody delivery to tissues of interest. The recent development of *in vivo* editing approaches designed to enhance scalability and feasibility in low and middle income countries could greatly accelerate the development of B cell-based therapies. Although these studies focused on treatments for people living with HIV, our approach holds promise for many chronic diseases in which standard of care includes repeated injections of antibody protein.

723 Neonatal Fc Receptor Inhibition Enables Adeno-Associated Virus Vector Gene Therapy Despite Pre-Existing Humoral Immunity

Makoto Horiuchi[1], Christian J. Hinderer[1], Lili Wang[1], Claude Warzecha[1], Hailey N. Shankle[1], Peter M. Hayashi[1], Jessica A. Chichester[1], Casey Kissel[1], Peter Bell[1], Rick A. Finch[2], Katrina M. Ralph[2], Luke J. Segura[2], Kathryn Shelton[2], Cecilia D. Dyer[1], Jenny A. Greig[1], James M. Wilson[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]MD Anderson Cancer Center, Bastrop, TX

Advances in adeno-associated virus (AAV)-based gene therapy are transforming our ability to treat rare genetic disorders and address other unmet medical needs. However, the natural prevalence of anti-AAV neutralizing antibodies (NAbs) in humans currently limits the population who can benefit from AAV-based gene therapies. Neonatal Fc receptor (FcRn) plays an essential role in the long half-life of IgG, a key NAb. Researchers have developed several FcRn-inhibiting drugs, including monoclonal antibodies, to treat autoimmune diseases, as inhibiting the FcRn-IgG interaction can reduce circulating IgG levels to 20%-30% of the baseline. We evaluated the ability of one such monoclonal antibody, M281 (nipocalimab), to reduce pre-existing NAb levels and thereupon enhance gene delivery to the liver and heart upon systemic administration of AAV gene therapy in mice and rhesus macaques (newborns and adults). M281 treatment prevented human NAb-mediated reduction in liver transduction by 83% (p=0.0039) following intravenous AAV administration in humanized FcRn transgenic mice to which pooled human IgG was passively transferred. In newborn rhesus macaques, M281 rapidly eliminated maternally derived anti-AAV antibodies and NAbs to below the detection limit. In adult rhesus macaques, M281 transiently reduced pre-existing NAb titers from 1:40-1:80 to 1:10 or lower along with total IgG levels; M281 treatment also enhanced gene delivery to the liver by 7.4-fold and to the heart by 61.4-fold after intravenous AAV administration in NAb-positive animals. These results indicate that mitigating pre-existing humoral immunity via disruption of the FcRn-IgG interaction may render AAV-based gene therapies effective in NAb-positive patients.

724 Preliminary Study of AntiAAVrh74 Seroprevalence Following Gene Transfer

Eleonora D'Ambrosio, Lingying Tong, Burcak Ozes, Kelly Lehman, Zarife Sahenk, Jerry R. Mendell

Gene Therapy, Nationwide Children's Hospital, Columbus, OH

The increasing number of gene therapy studies and exclusion of candidates from clinical trials highlights the potential importance of pre-existing antibodies targeting viral capsid. Viral antibodies block transduction and preclude expression of the transferred gene. Provoked immune response could also be a threat to safety. Testing patients for pre-existing antibodies, either neutralizing (Nabs) or total/binding (TAbs/BAbs), prior to gene transfer is a critical step in the initiation of a clinical trial. Previous studies assessed the seroprevalence of antibodies against different AAV subtypes in the general population and in patients receiving gene transfer. Our gene therapy studies for muscular dystrophy (DMD, LGMD) have currently shown promise for efficacy and safety, but we don't know if vector shedding post gene delivery affects the antibodies titer in family members of trial participants. This is particularly relevant for siblings who might become next gene therapy candidates. This pilot study included 115 subjects divided in three separate cohorts. Group 1 consisted of hospital personnel without known prior work exposure to rAAVrh74 (control group, 23 subjects). Group 2 were hospital-based personnel with known work exposure to rAAVrh74 (through pre-clinical and clinical studies, or direct contact with patient's specimen, 35 subjects) and Group 3 were relatives of patients receiving rAAVrh74 as part of a gene transfer trial (57 subjects). Enzyme-linked immunosorbent assay (ELISA)-based detection was used to identify anti-AAVrh74 total antibodies. Titers of 1:50 and 1:400 were reported, considering the range of titers used for enrollment in different trials. We found that parents of patients receiving gene transfer had a 3-fold greater risk of AAVrh74 seropositivity at 1:50 compared to the control group: 33.3% AAVrh74 positive (19/57 subjects) vs 13% negative (3/23 subjects), with a relative risk of 2.6%. Additionally, we observed that there were no statistically significant differences between two hospital personnel cohorts, non-exposed (Group 1) and exposed (Group 2), in terms of antibody positivity to AAVrh74. Finally, antibody titers at 1:400 were not different between Groups 1,2, or 3. These preliminary results serve as a caution to family members caring for children undergoing AAV gene transfer, warning that viral shedding following gene transfer can have an effect on the antibody titers. Prospective studies are on the way, with greater sample size, inclusive of pre- and post-treatment testing, and with the objective of establishing both the antibodies cut-off titers and the risk for acquiring immunity that could preclude gene transfer.

725 Specific Pharmacological Blockade of IRAK4 Suppresses AAV Induced Immunogenicity

Mincheol Park, Mona Motwani, Margaret Hennessy, Sourav R. Choudhury

AAV Technologies Laboratory, Genomic Medicine Unit, Sanofi, Waltham, MA

Immune responses to adeno-associated viruses (AAVs) pose a major challenge for successful clinical translation of gene therapy. Studies

based on several mouse models show that the innate immune DNA sensor TLR9 recognizes CpG-rich hypomethylated DNA in the transgene of AAV vectors. TLR9-triggered signaling cascade activates adaptive immune responses that ultimately lead to clearance of transgene induced cells by T cell mediated cell cytotoxicity. In line with this, data from hemophilia clinical trials reveal that reduction in total number of CpG bases reduces the need for pharmacological immunosuppressants and show reduced cytotoxic T lymphocyte responses in hemophilia patients. While broadly acting immune suppressants have been successful in improving AAV delivery in clinical trials, they still result in loss of transgene expression and present with side effects and risk of opportunistic infections. Developing vectors with no CpG nucleotides is challenging because non-codon optimized vectors (i.e., vectors with no or low CpG content) typically exhibit poor transgene expression. Hence, what is needed is a different class of immune modulators that show enhanced specificity and low side effects. IRAK4 is a key kinase within the TLR9 pathway, which is critical for mounting an effective innate immune response. We hypothesized that inhibiting IRAK4 by kinase inhibitors or degraders should result in a specific blockade of TLR pathway resulting in immune modulation favorable for AAV treatment. To this end, we tested commercially available inhibitors/degraders of IRAK4 to block TLR9 signaling in-vitro. We utilized primary human monocyte derived dendritic cells (moDCs) that were either untreated or pre-treated with IRAK4 inhibitor/degrader before AAV infection. We have previously described the detection of a consistent statistically significant increase in cytokine 'signature' (IL1b, TNFa and IL6) resulting from AAV administration to moDCs. Here, we observed that moDCs pre-treated with IRAK4 inhibitor or degrader showed significant reduction in AAV induced signature cytokines as compared to cells that were not treated with IRAK modulators. In addition, both the IRAK4 inhibitor and degrader were not cytotoxic to primary human dendritic cells and resulted in more than 50% IRAK4 degradation. To further extend these novel findings we are testing different doses of both IRAK4 inhibitor/degrader delivered one time either as pre-treatment (prior to AAV infusion) in an in-vivo mouse model of AAV immunogenicity. Applicability of this strategy has the promise to be pan-indication, such as Huntington disease, metachromatic leukodystrophy, amyotrophic lateral sclerosis, hemophilia A, and enable successful clinical translation of AAV gene therapy.

726 Neutralizing Antibody Depletion with Imlifidase - A Potential Way to Enable AAV Based Gene Therapy in Seropositive Patients

Nathalie Uzcátegui, Catja Freiburghaus, Xingmei Zhang, Eva Erlandsson, Sara C. Nilsson, Fatima Ahmad, Annika Sundberg, Anna Runström, Christian Kjellman, Lena Winstedt

Hansa Biopharma, Lund, Sweden

Pre-existing neutralizing antibodies towards adeno associated virus (AAV) based gene therapy are a major problem, as they are present in 30-60% of patients, making them ineligible for successful gene therapy treatment. However, these neutralizing antibodies can be effectively depleted by imlifidase, an IgG cleaving cysteine protease originating from *Streptococcus pyogenes*. Imlifidase, with the tradename Idefirix®, has been granted a conditional marketing authorization in Europe* for desensitization of highly sensitized adult kidney transplant patients. In addition, there are several ongoing clinical trials in a variety of indications, with IgG antibodies and Fc-mediated effector responses as their common denominator. More than 99% of all IgG is efficiently cleaved within a few hours after dosing with one or two doses of the clinically used dose of 0.25 imlifidase mg/kg body weight. Newly synthesized IgG starts to show 5-7 days after dosing of imlifidase, thus creating an antibody-free window of approximately one week. IgG levels are normally restored to their initial levels after 2-6 months. Imlifidase has demonstrated an acceptable safety profile in clinical trials in kidney transplantation, anti-GBM disease and Guillain-Barré syndrome (GBS) with the most common adverse events being infection (16.5%) and infusion related reactions (5.6%), resolving within 90 min. The most common treatment related serious adverse events reported in this population were pneumonia (6%) and sepsis (4%). There were no serious adverse events reported in all 35 healthy subjects treated with imlifidase. All in all, antibody depletion with imlifidase could offer a simple and elegant way to enable gene therapy in seropositive patients with AAV antibodies and supports the rational for further clinical studies. The therapeutic effects of imlifidase established in various indications are thus being further evaluated in AAV based gene therapy in collaboration with gene therapy companies, including Sarepta Therapeutics and AskBio.
*EU/EEA, UK and Switzerland

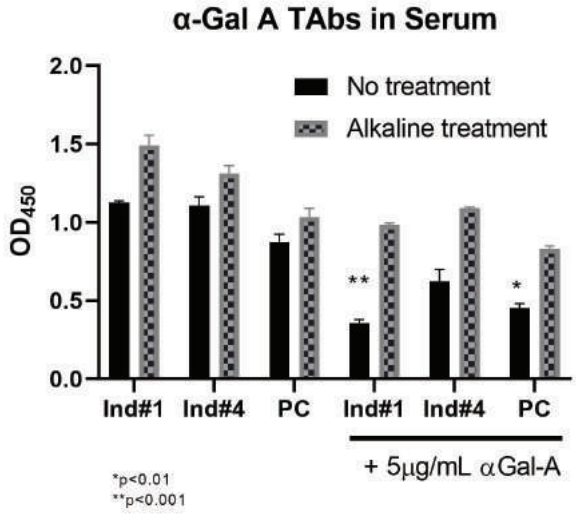
727 Overcoming the Effect of Previous Enzyme Replacement Therapy on the Detection of Anti-Transgene Protein Antibodies after Treatment with Gene Therapy

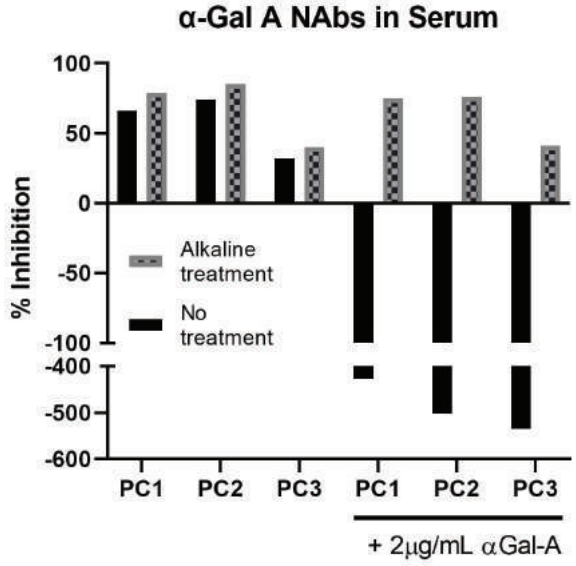
Josh Holter, Ruby Cheung, Khaled Hettini, Jing Hu, Yanmei Lu, Liching Cao

Sangamo Therapeutics, Inc., Brisbane, CA

The increasing interest of *in vivo* gene therapy using recombinant adeno-associated virus (AAV) brings new bioanalytical challenges for assessing immunogenicity. Many AAV gene therapies in the clinic target lysosomal storage disorders with patient populations that are being treated with enzyme replacement therapy (ERT). Patients often develop high levels of persistent anti-drug antibodies (ADA) to the recombinant enzyme products that may have an impact on later gene therapy treatments. As such, there is a need to appropriately measure ADA and its potential impact on pharmacokinetics, pharmacodynamics, safety, and efficacy. Additionally, it is important during gene therapy drug development to be able to monitor relative ADA levels to assess the induction of tolerance or treatment-boosted ADA production for patients with pre-existing ADA. Typical methods for detecting ADA to lysosomal enzymes are generally intolerant to low levels of circulating enzyme. In order to appropriately determine ADA levels, it is required to assess at washout, which is not possible after administration with AAV gene therapy. In patients with Fabry disease, treatment with gene therapy results in continuous expression of lysosomal transgene enzyme, alpha galactosidase A (α-Gal A), which can interfere with the detection of ADA and assessment of changes in ADA levels. In order to address this interference, novel assay methods were developed to improve the enzyme tolerance of our anti-α-Gal A total antibody (TAb) and neutralizing antibody (NAb) assays. Specifically, inclusion of a sample

pre-treatment with alkaline buffer dissociated α-Gal A ADA immune complexes and selectively denatured circulating α-Gal A, thereby leaving ADA intact and free for detection in our TAb and NAb assays.





Improvement of anti-α-Gal A antibody assays with the incorporation of an alkaline pretreatment step.The left figure shows improvement in TAb detection Fabry patient serum as well as positive controls. The right figure shows improvement in NAb detection in three different positive control antibodies. *p<0.01 ; **p<0.001 ; PC-Positive Control ; Ind-Individual With this novel approach we demonstrate an improvement in circulating enzyme tolerance to microgram per milliliter levels in serum for both the TAb and NAb assays, with elimination of enzyme interference in the NAb to the highest α-Gal A level tested. The alkaline treatment was able to remove enzyme interference with positive control antibodies as well as with Fabry patient samples with pre-existing ADA to ERT, thus leading to a more accurate detection of ADAs regardless of the on-board α-Gal A enzyme levels. This method provides high enzyme level tolerance and allows for the detection of changes in ADA level due to treatment or immune tolerance. Due to the similar nature and functional pH of lysosomal enzymes, we believe this method is applicable for accurate antibody detection for other lysosomal storage diseases and may be invaluable in determining the impact of AAV gene therapy on pre-existing anti-ERT immunogenicity.

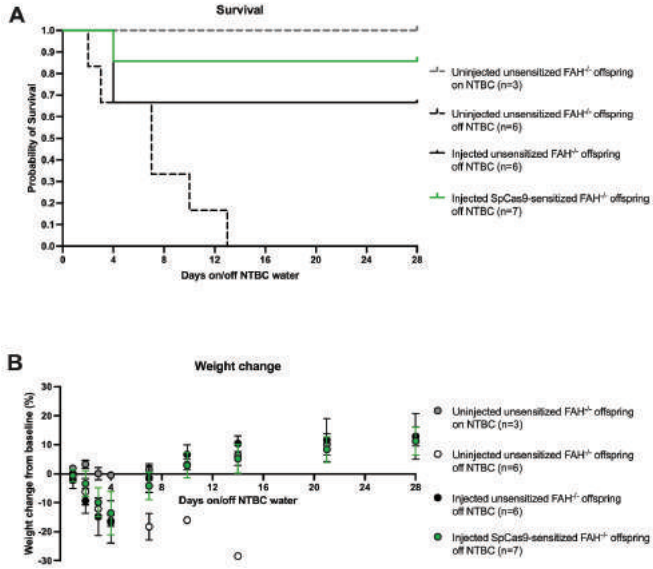
728 CRISPR-Cas9 In Utero Correction of Murine Tyrosinemia is Not Impaired by Pre-Existing Maternal Immunity to Cas9 Endonuclease

John S. Riley[1], Valerie L. Luks[1], Cara L. Berkowitz[1], Ana Maria Dumitru[1], Philip W. Zoltick[1], William H. Peranteau[2]

[1]Center for Fetal Research, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Center for Fetal Research, The Children's Hospital of Philadelphia, Philadelphia, PA

PURPOSE: In utero gene editing (IUGE) is an experimental treatment for inherited metabolic liver diseases including hereditary tyrosinemia type 1 (HT1). We have previously reported phenotypic correction in a mouse model of HT1 by means of in utero base editing of the *Hpd* gene, which codes the enzyme 4-hydroxyphenylpyruvate dioxygenase upstream in the tyrosine catabolism pathway, thereby preventing the lethal accumulation of toxic metabolites (Rossidis et al. *Nat Med* 2018). Pre-existing immunity to Cas9 endonuclease causes cytotoxic T cell-mediated destruction of CRISPR-Cas9-edited hepatocytes in adult mouse models (Li et al. *Mol Ther* 2020). Here we investigate whether pre-existing maternal immunity to Cas9 endonuclease impairs therapeutic gene editing of the fetal liver for HT1.
METHODS: Nitisinone (NTBC) is a medication that blocks the activity of 4-hydroxyphenylpyruvate dioxygenase. *Fah*$^{-/-}$ mice, a model of HT1, universally develop hepatitis, failure-to-thrive, and death in the absence of NTBC delivered via their mother's breast milk prior to weaning and in their water supply thereafter. We designed an adeno-associated virus serotype 9 (AAV9) containing the *Strep pyogenes* Cas9 endonuclease (SpCas9) transgene and a guide RNA for induction of indels in the murine *Hpd* gene (AAV9.SpCas9.Hpd). Maternal immunity to SpCas9 was induced by intramuscular injection of SpCas9 protein with saponin adjuvant 28 and 21 days prior to fetal injection of AAV9.SpCas9.Hpd, with successful induction of maternal cellular immunity confirmed by delayed-type hypersensitivity reaction. Gestational day 16 *Fah*$^{-/-}$ fetuses were injected with 10^{14} vg/kg of AAV9.SpCas9.Hpd. Offspring were maintained on NTBC until 6 weeks of age. Subsequent survival off NTBC was compared among experimental and control groups using the Log-rank (Mantel-Cox) test of equality of survival curves, and weight change from baseline was compared using analysis of variance. Fetal survival to birth was compared using Chi-square. Age-matched uninjected *Fah*$^{-/-}$ mice maintained on NTBC and taken off NTBC served as healthy and disease controls, respectively.
RESULTS: In utero injection of AAV9.SpCas9.Hpd resulted in 67% survival off NTBC among offspring of unsensitized *Fah*$^{-/-}$ dams (Figure 1A). Transient weight loss was observed in the first 4 days off NTBC with recovery to baseline by 7 days and continued weight gain above baseline thereafter (Figure 1B). Injected offspring of SpCas9-sensitized dams demonstrated equivalent survival off NTBC compared to injected offspring of unsensitized dams (86% vs. 67%, P=0.6). Weight change off NTBC followed a similar trajectory and was equivalent at all

timepoints (P≥0.32). Additionally, pre-existing maternal immunity to SpCas9 was not associated with adverse pregnancy outcomes and did not affect fetal survival to birth (53% vs. 67%, P=0.38). **CONCLUSION:** Pre-existing maternal immunity to SpCas9 does not impair in utero gene editing of the *Hpd* locus via AAV delivery of SpCas9 and *Hpd* targeting gRNA with rescue of the HT1 disease phenotype. This suggests a possible immunologic advantage for a fetal gene editing approach.



729 Non-Canonical Nucleic Acid Structures for Regulating the Immunostimulatory Effect of mRNA Therapeutics/Vaccines

So Ra Son, Minsa Park, Kyuri Lee

Gyeongsang National University, Jinju-daero, Jinju-si, Gyeongsangnam-do, Korea, Republic of

The modulation of PRRs-mediated recognition of exogenously delivered mRNA is important in the development of mRNA vaccine. The PRRs-mediated immune stimulation can be beneficial for the vaccine effect but can activate antiviral responses that limit antigen expression. In the context of RNA structures, long dsRNA and dsRNA with 5´triphosphate groups can be recognized by MDA5 and RIG-I, stimulating immune reaction but reducing antigen expression efficiency. To compromise this issue, current mRNA vaccines utilize the chemical modification technique for reducing immune stimulation and increasing antigen expression efficiency. To improve the current mRNA vaccine effect, it is crucial to find a way to induce immune stimulation without losing antigen expression efficiency. In this study, we developed non-canonical nucleic acid structures that can regulate the immunostimulatory effect of mRNA. The immunostimulatory effect of the developed nucleic acid structures was evaluated by measuring type I interferon (IFN) and secreted alkaline phosphate (SEAP) activities in the macrophage-like THP-1 Dual cells. By introducing the designed non-canonical nucleic acid structures into mRNA structure, the immunostimulatory effect of mRNA was controlled without chemical modification technique.

730 Liver-Specific Transgene Expression Attenuates Pre-Existing T Cell Responses but Fails to Prevent Transgene Loss

Nicholas Giovannone, Nyanza Rothman, Laura Johnsen, Aris Economides, Andrew Baik, Katherine Cygnar

Regeneron Pharmaceuticals, Tarrytown, NY

Liver is viewed as a tolerogenic organ at steady-state, favoring induction of regulatory immune responses over pro-inflammatory responses. In the context of gene therapy, restricting transgene expression to the liver using liver-specific promoters has emerged as a potential strategy to attenuate *de novo* anti-transgene immune responses. However, while many studies have shown that liver-specific expression can promote immune tolerance to transgene in naïve mice, fewer studies have examined whether liver transgene expression can therapeutically suppress pre-existing anti-transgene immunity, and to what extent. Here, we investigated whether liver-restricted transgene expression could suppress strong pre-existing immunity in mice. Using an AAV8 vector, we expressed a foreign transgene (anti-human CD63 scFv fused to human acid alpha-glucosidase, "scFv:GAA") under a liver-specific transthyretin promoter, in either naïve Pompe (GAA-deficient) mice or mice previously immunized with scFv:GAA protein in Complete Freund's adjuvant (CFA). We found that while AAV-mediated liver expression protected previously naïve mice from developing antibody and T cell responses to scFv:GAA, even following CFA-adjuvanted immunization, antigen-experienced mice showed persistently high anti-GAA antibody titers, lymphocytic liver infiltrates (B and T cells), and partial transgene loss after AAV treatment. Functionally, high-titer pre-existing anti-GAA antibodies blocked therapeutic correction of tissue glycogen storage, including in heart and skeletal muscle. However, despite transgene loss and impaired glycogen clearance, there was evidence of a counter-regulatory response, including persistent PD-1 expression on liver T cells, upregulation of PD-L1 in the liver microenvironment, increased liver regulatory CD4+ T cells, and attenuation of systemic transgene-specific T cell responses by IFN-gamma ELISpot. Collectively, these data suggest while liver expression may suppress systemic transgene-specific T cell responses, it alone is insufficient to reverse entrenched, high-titer antibody responses and prevent liver transgene loss. While translatability to humans remains to be established, these results suggest the clinical benefit of liver-induced immune tolerance in liver-directed AAV gene therapies may depend on the strength of pre-existing immunity to transgene.

731 The HLA Class-II Immunopeptidomes of AAV Capsids Proteins

Carlos Andres Brito Sierra[1], Megan Lannan[1], Laurent Malherbe[2], Robert Siegel[1]

[1]Eli Lilly & Company, Indianapolis, IN,[2]Eli Lilly and Company, Indianapolis, IN

Introduction: Gene therapies are using Adeno-associated viruses (AAVs) as vectors, but immune responses against the capsids pose challenges to their efficiency and safety. Helper T cell recognition of capsid-derived peptides bound to human leukocyte antigen (HLA) class II molecules is an essential step in the AAV-specific adaptive immunity.**Methods:** Using MHC-associated peptide proteomics, we

identified the HLA-DR and HLA-DQ immunopeptidomes of the capsid proteins of three different AAV serotypes (AAV2, AAV6, and AAV9) from a panel of healthy donors selected to represent a majority of allele usage.**Results:** The identified sequences span the capsids of all serotypes, with AAV2 having the highest peptide count. For all the serotypes, multiple promiscuous peptides were identified and displayed by both HLA-DR and -DQ. However, despite high sequence homology, there were few identical peptides among AAV2, AAV6, and AAV9 immunopeptidomes, and none were promiscuous.**Discussion:** Results from this work represent a comprehensive immunopeptidomics research of potential CD4+ T cell epitopes and provide the basis for immunosurveillance efforts for safer and more efficient AAV-based gene therapies.

732 Improving Lentiviral Gene Therapy by Inhibiting the Innate Immune Response

Eric J. Warga[1], Jacob Elmer[2]

[1]Chemical and Biological Engineering, Villanova University, Villanova, PA,[2]Villanova University, Villanova, PA

With the advent of CAR-T therapy and other *in vivo* gene therapies like Zynteglo, lentiviral gene delivery has become a successful way to address severe chronic disorders. Lentivirus-derived vectors integrate their therapeutic transgenes into patient cells with generally high efficiency. However, sometimes extreme interpatient variability in lentiviral transduction efficiency is observed, and this can lead to suboptimal transduction in some cases (e.g. 34%-76% of patient cells transduced in clinical trial NCT03233854). While the adaptive immune response is known to hinder *in vivo* gene therapy, our research focuses on how the **innate** immune response of cells can negatively affect lentiviral transgene expression, even *ex vivo*. (Figure 1)

Figure 1. Potential inhibition of steps in the lentiviral gene delivery process by known AVGs. IFITM3 is a known inhibitor of the entry of lentiviral vectors into cells. AVGs IFI16 and Sp100 are involved in the silencing of foreign genetic material, even post-integration, and could potentially be responsible for the lack of transgene expression. MT1H is the only gene with any known antiviral role to significantly increase in expression because of lentiviral transduction. **In this study, we sought to elucidate the genes in the immune response that impact lentiviral gene delivery the most, then leverage this knowledge to design novel small molecule inhibitors for these genes. These inhibitors, once developed, will be inexpensive and easy to implement into lentiviral gene delivery processes for improved transduction efficiency.** Our study thus far has involved performing extensive mRNA sequencing to measure transcriptome-wide host cell gene expression of healthy donor PBMCs during the CAR-T manufacturing process and comparing this data to the transcriptome of HEK-293T cells, which have a consistently high transduction efficiency. The results indicated that several antiviral genes (AVGs) that are known to restrict lentiviruses were absent from HEK-293T cells but expressed at high levels in the PBMCs regardless of transduction throughout the entire *ex vivo* culture process. Analysis of the mRNA-seq data and extensive literature review yielded an ordered list of AVGs that are the most potent against lentiviral transgenes, and the top 4 were selected from this list for Cas9 KO and inhibition with siRNAs and/or small molecule inhibitors (SMIs), to determine if inhibiting these targets can improve transduction efficiency or transgene expression. (Table 1)

733 Xork-Fc, an Engineered IgG Protease, Shows Low Cross-Reactivity to Pre-Existing Antibodies in Human Serum and Enables Efficient AAV Transduction in an *In Vivo* Model of Passive Transfer of Neutralizing Human Serum

Ning Li[1], Alicia M. Michaud[1], Teresa Capela[1], Houqing Yu[1], Jingping Ge[1], Pooja Swami[1,2], Maria Nordgren[3], Rolf Lood[1], Sheldon S. Leung[1], Petr O. Ilyinskii[1], Kei Kishimoto[1]

[1]Selecta Biosciences, Watertown, MA,[2]Northeastern University, Boston, MA,[3]Genovis, Lund, Sweden

Pre-existing neutralizing antibodies against AAV are highly prevalent and are a major exclusion factor for enrollment into many gene therapy trials. New strategies are needed to expand access of critical gene therapies to patients with pre-existing anti-AAV antibodies. Recently, bacterial-derived proteases specific for human IgG have been proposed as a method to transiently clear IgG from circulation and open a window within which AAV can be administered. We describe here the development of a novel IgG-specific protease, IdeXork (Xork). In contrast to IdeS, an IgG protease derived from the common human pathogen Streptococcus pyogenes, Xork is derived from a Streptoccocus species that is not known to infect humans. Consequently, levels of pre-existing antibodies against Xork are low or absent in normal human serum compared to the moderate-high levels of pre-existing antibodies that are prevalent against IdeS. We demonstrate that Xork cleaves human IgG in vitro with the same specificity and mechanism as IdeS. The in vivo activity of Xork was optimized by creation of an Fc fusion protein to extend its half-life. Near-complete (up to 97%) inhibition of AAV transduction in vivo by passive transfer of human serum with pre-existing anti-AAV antibodies was efficiently prevented by treatment with Xork-Fc. Combining Xork-Fc with ImmTOR tolerogenic nanoparticles has the potential to prevent de novo formation of anti-Xork antibodies and enable re-dosing of Xork.

734 Investigation of Hindlimb Clasping Following Intrathecal AAV9 Delivery

Meghan Eller, Krishanna Knight, Irvin T. Garza, Rachel M. Bailey

UT Southwestern Medical Center, Dallas, TX

With the growing advancements in AAV gene therapy and FDA-approved treatments, researchers are increasing their focus on possible adverse events following AAV delivery. Intrathecal delivery of AAV9 is often used to treat neurological and neuromuscular diseases. Despite promising therapeutic benefit, preclinical studies across different species have identified dorsal root ganglia (DRG) pathology following delivery of AAV9 by this route. Immune responses underlie DRG

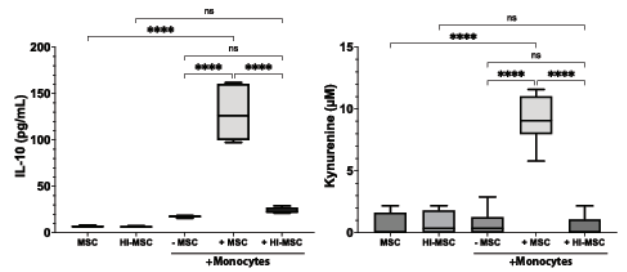
toxicity, which may be caused by the capsid, transgene expression, or poor vector quality. Further studies are needed to understand this phenomenon. While DRG toxicity has been observed in non-human primates following AAV delivery, this has not yet been seen in mouse models. In this study, we aimed to investigate factors that may contribute to DRG toxicity: high viral doses, high transgene expression, and genome heterogeneity within manufacturing. In all studies, wildtype mice were treated with self-complementary AAV9 at post-natal day 10 via intrathecal lumbar puncture and were monitored weekly for weight, survival, and hindlimb clasping. At 8-weeks post-injection, tissues were harvested for quantification of transgene expression and histopathology assessments. To examine the effect of transgene expression, we administered vectors containing a weak or strong ubiquitous promoter to drive differential expression of the same transgene. To test the influence of genome size on DRG toxicity, mice were treated with vectors carrying the same promoter and transgene, but either 1.3kb or 2kb of DNA sequence between the inverted terminal repeats. A GFP coding sequence was added downstream of the transgene of interest in the 1.3kb construct to generate the 2kb construct, which is closer to the optimal packaging size of 2.4kb for self-complementary vectors. Across treatments or compared to vehicle, no differences in weight or survival were observed. Notably, progressive hindlimb clasping developed 4 weeks after administration in 60% of mice treated with the 1.3kb construct and was absent in mice treated with the 2kb vector. This behavior was independent of sex and litter and occurred in animals that were treated on different days. Hindlimb clasping has previously been associated with spinal cord atrophy in mouse models of ALS, however to our knowledge this behavior has not been directly associated with AAV. We did not find any relationship between transgene expression and hindlimb clasping, suggesting excess protein expression is not responsible. We hypothesize that the small genome size of 1.3kb resulted in packaging of DNA backbone past the ITRs, which was recently reported to cause adverse immune responses. Single molecule, real-time (SMRT) sequencing will be used to determine the DNA content that was packaged. Histopathological assessments of the DRG and additional organs are ongoing and will be reported. The findings from this study emphasize the importance of expression cassette design and size when developing AAV vectors for gene therapy and caution greater scrutiny of the packaged product.

735 Monocytes That Efferocytose Viable, but Not Heat Inactivated, MSCs Adopt a Distinct Immmunoregulatory Phenotype

Michael V. Schrodt, Riley M. Behan-Bush, Jesse N. Liszewski, Lauren K. Boland, Madeleine E. Humpal-Pash, James A. Ankrum

Roy J. Carver Department of Biomedical Engineering, University of Iowa, Iowa City, IA

Intravenously infused MSCs are rapidly cleared from the body, yet a potent immunotherapeutic response is still observed. Recent work suggests that monocytes contribute to the clearance of MSCs via efferocytosis which begs the question of how variations in MSC health affect monocyte phenotypic response. We sought to characterize viable and HI-MSC efferocytic-licensed human monocytes by surface marker and soluble factor analysis to determine their phenotypic response. Human PBMCs and umbilical-cord MSCs were co-cultured for 24hr in complete culture media in polypropylene V-bottom microplates. To assess monocyte efferocytosis of MSCs, MSCs were stained with CellBrite Orange (CBO) membrane dye prior to co-culture. MSCs were either viable or heat-inactivated prior to the 24hr co-culture. Heat-inactivation was performed by 30-minute incubation of cells in a 50°C water bath. Following 24hr MSC:PBMC co-culture, monocytes were stained with fluorescent antibodies for CD14, CD16, CD86, CD163, and CD206 to assess changes in surface marker expression due to efferocytic-licensing by either viable or HI-MSCs. To assess monocyte soluble factor changes due to efferocytic-licensing with either viable or HI-MSCs, monocytes were isolated from PBMCs by negative selection prior to co-culture with MSCs. Viable MSC, HI-MSC, and monocyte only controls were plated as well. After the 24hr culture, all samples were re-plated to a polystyrene flat-bottom microplate with complete media supplemented with 200μM L-tryptophan. The samples were allowed to culture for an additional 2 days after which media was collected from all samples and assessed for IDO activity by kynurenine production and IL-10 by ELISA. All data was analyzed using GraphPad Prism 9 and all flow cytometry data was processed using FlowJo prior to statistical analysis. Surface marker analysis of monocytes following efferocytic-licensing with viable and HI-MSCs showed no significant difference in CD14 or CD16 expression compared to control. Expression of CD86 increased significantly in classical and intermediate monocytes efferocytically-licensed with viable MSCs while both viable and HI-MSC efferocytic-licensing resulted in significant CD86 expression of non-classical monocytes compared to control. CD163 expression significantly decreased for classical and intermediate monocytes that were efferocytically-licensed with viable MSC compared to control. Efferocytic-licensing of monocytes with viable MSCs, but not HI-MSCs, resulted in significant increases in IL-10 production and IDO activity compared to controls. Our work shows that efferocytic-licensing of human monocytes by MSCs results in distinct immunosuppressive phenotypic profiles depending on the health of the MSC utilized. The combination of increased CD86 expression, IL-10 production, and IDO activity with decreased CD163 expression is indicative of a potent immunosuppressive monocyte phenotype in response to efferocytosis of viable MSC. The combination of a slight increase in CD86 expression and no change in CD163 expression, IL-10 production, or IDO activity is indicative of a mild change in monocyte phenotype in response to efferocytosis of HI-MSC. This extends our understanding of MSC therapy by showing that efferocytosis of viable MSCs leads to immunosuppression by monocytes mediated by IL-10 and IDO.



Viable MSC efferocytic-licensed monocytes adopt an immunoregulatory phenotype. Monocytes cultured with viable MSCs for 24hr exhibit significant increases in IL-10 production and IDO activity compared to controls. HI-MSCs had no effect on IL-10 production or IDO activity.

736 Single Marker cMPL Enriches Long-Term Repopulating Human Hematopoietic Stem Cells

Daisuke Araki, Christi Salisbury-Ruf, Andre Larochelle
National Institutes of Health-NHLBI, Bethesda, MD

Current gene therapy protocols for the treatment of inherited human blood disorders mostly rely on *ex vivo* genetic correction of mobilized peripheral blood (MPB) CD34+ hematopoietic stem and progenitor cells (HSPCs), a heterogenous cell population with predominantly lineage restricted progenitors and rare long-term repopulating hematopoietic stem cells (LTR-HSCs). Strategies to enrich LTR-HSCs within MPB CD34+ HSPCs could improve the efficiency of gene correction in these cells and enable broad clinical accessibility by reducing reagent cost. In humans, hematopoietic cells with a CD34+CD38-CD45RA-CD90+CD49f+ immunophenotype represent a population with the highest reported purity of LTR-HSCs. However, this subset remains heterogenous (Huntsman, Blood 2015) and the complex combination of markers precludes identification of LTR-HSCs in tissue sections. The hematopoietic cytokine thrombopoietin and its cognate receptor cMPL act as primary regulator of HSPC function. Surface expression of cMPL can enrich LTR-HSCs in mice, but its utility for purification of human LTR-HSCs has not been investigated. In this study, we sought to investigate whether cMPL can serve as a reliable and simpler marker to enrich LTR-HSCs in human adult CD34+ HSPCs. We first obtained MPB CD34+ cells from healthy volunteers and confirmed that surface cMPL expression measured by flow cytometry was significantly higher within the CD34+CD38-CD45RA-CD90+CD49f+ cell fraction relative to bulk CD34+ cells. To determine whether cMPL can enrich functional LTR-HSCs, we used fluorescence-activated cell sorting to partition human MPB CD34+ cells into $cMPL^{high}$ (top 10%) and $cMPL^{low}$ (bottom 10%) populations, and transplanted these cells into immunodeficient NBSGW mice. Serial peripheral blood (PB) sampling of primary xenografted mice revealed a striking difference in patterns of hematopoietic reconstitution over time between the two groups. In mice transplanted with $cMPL^{high}$ cells, human cell chimerism increased gradually throughout the 16-week engraftment period, while a progressive decline in engraftment was observed in the $cMPL^{low}$ group. Notably, mean human cell engraftment within the PB, bone marrow (BM) and spleen of mice transplanted with $cMPL^{high}$ cells was 209-fold ($p < 0.01$), 37-fold ($p < 0.0001$) and 283-fold ($p < 0.001$) higher than mean human cell chimerism in the $cMPL^{low}$ group at 16 weeks post-transplantation, respectively. These data suggest that $cMPL^{high}$ and $cMPL^{low}$ populations are distinctly enriched in LTR-HSCs and hematopoietic progenitors, respectively. Next, to quantitatively compare the frequency of self-renewing LTR-HSCs within the $cMPL^{high}$ and $cMPL^{low}$ HSPC subsets, human CD45+ cells obtained from the BM of primary mice were injected into secondary NBSGW mice at limiting dilution and BM engraftment was measured at 16 weeks post-transplantation (total period of engraftment: 32 weeks). After accounting for engraftment parameters (i.e., cell dose and engraftment levels) in both primary and secondary mice, extreme limiting dilution analysis computed LTR-HSC frequencies of 1 in 1,267 within the $cMPL^{high}$ CD34+ cell population, and 1 in 149,010 in the $cMPL^{low}$ CD34+ cell fraction, representing a 116-fold enrichment of LTR-HSCs using cMPL as a single marker purification strategy. Globally, our data suggest that cMPL effectively enriches LTR-HSCs in human adult CD34+ HSPCs. We foresee that a more stringent sorting scheme of $cMPL^{high}$ cells (e.g., top 1%) would enable further LTR-HSC enrichment that could approximate single-cell resolution. Additional studies are ongoing to evaluate the utility of a cMPL-based HSC purification strategy in the context of autologous HSC gene therapy.

737 Development of Short-Term and High-Efficiency Motor Neuron Induction and Enrichment Methods from iPS Cells Using Adenoviral Vectors

Yumi Kanegae, Miyuki Agawa
Research Center for Medical Science, Jikei University School of Medicine, Tokyo, Japan

Human pluripotent stem cells (hPSCs) are expected to be applied to the in vitro modeling of human intractable disorders and regenerative therapy. In particular, since neurons cannot be isolated from humans, induction of differentiation from human induced pluripotent stem cells (hiPSCs) into target neurons is highly useful for disease analysis and treatment of neurological disorders. Although rapid, efficient, and simple differentiation and induction methods using various inhibitors combination or viral vectors expressing differentiation-inducing factors have already been reported, problems such as contamination of undifferentiated cells still remain.In this study, we constructed two kinds of adenovirus vector (AdV) to induce differentiation of motor neurons from iPS cells, and showed rapid and efficient differentiation efficiency not only via Neurosphere but also direct induction method. Moreover, in order to remove the remaining undifferentiated cells, we examined the usefulness of AdV expressing a drug resistance gene. 201B7 cells and ChipSC18 cells were used as iPS cells. To demonstrate induction of motor neuron, we used ChAT for immunofluorescence and Hb9 for quantitation of mRNA levels.First, we compared the induction efficiency of motor neurons from iPS cells via Neurosphere, which is commonly performed. For this, we constructed the AdV (three-factor AdV) carried with Ngn2, Isl1 and Lhx3. After preparing Neurospere, we compared the motor neuron induction efficiency by the conventional inhibitor combination method (adding SHH, retinoic acid, and IGF-I) and the method of transducing with three-factor AdV. Three-factor AdV was confirmed to have significantly more ChAT-positive cells than the conventional method. In addition, the expression level of Hb9 was 7 times higher than that of the conventional method. In particular, many ChAT non-positive cells mixed and proliferated in the conventional method. We constructed the enrichment-AdV that specifically expresses the puromycin resistance gene in neurons and transduced it into mixed cells. We have successfully enriched motor neurons.Next, we examined whether motor neurons can be directly induced from iPS cells using miRNA-carried AdV (miRNA-AdV) that expresses miRNA in addition to the above three factors. With conventional methods, it took more than 3 weeks to induce motor neurons, but by using miRNA-AdV, ChAT-positive cells were detected in just 9 days from the start of induction. In 201B7 and ChipSC18 cells, ChipSC18 cells showed higher induction efficiency than 201B7 cells, especially in the direct induction method.These results suggest that this method is highly useful as a short-term, high-efficiency induction method for motor nerves. We believe that these methods can be expected to be applied to the safe treatment of diseases such as spinal cord injury.

738 Comparative Analysis of Gene Expression and Growth Factor Secretion in Stem Cells from Human Exfoliated Deciduous Teeth (SHED) and Other Tissue-Derived Mesenchymal Stem Cells; Therapeutic Potential with SHED for Neurological Diseases

Hiromi Takaki-Ariki, Mei Natori, Noritaka Fukuda, Tetsuro Nakamura, Yosuke Nakayama, Yasuyuki Mitani
Kidswell Bio Corporation, Tokyo, Japan

Stem cells from human exfoliated deciduous teeth (SHED) are mesenchymal stem cells (MSC) isolated from the dental pulp, the tissue derived from neural crest cells. SHED express surface MSC markers (positive for CD90, CD105 and CD73, negative for CD45, CD19, CD14, CD34 and HLA-DR), and have abilities of colony formation and trilineage differentiation same as other tissue-derived MSCs. To clarify differences between SHED and other MSCs, gene expression profiles of SHED were compared with those of MSCs derived from bone marrow (BM), adipose tissue (AT), and the third molar dental pulp (DP) on multiple donors. Principal component analysis and hierarchical cluster analysis showed that SHED have a distinct gene expression pattern from other MSCs and were classified in a different cluster. Gene ontology analysis revealed neurogenic, angiogenic, and cell migration-related genes were significantly more enriched in SHED than BM and AT MSCs, reflecting their neural crest derivation. Indeed, comparative cell culture studies demonstrated that SHED secreted some of neurotrophic, angiogenic, and migration factors more abundantly than other MSCs. Further, conditioned media with SHED enhanced the induction of anti-inflammatory M2-type macrophages from THP-1 monocytes more efficiently than those with other MSCs. Finally, we evaluated a therapeutic efficacy of SHED on a chronic stage of rat spinal cord injury model. Repetitive intravenous and intrathecal administration of SHED regenerated myelin sheath and improved a locomotor function. These results indicate that SHED possess high neuro-regenerative and anti-inflammatory capacities and should be a promising cell therapeutics for neurological diseases even at the chronic stage.

739 GNTI-122 is a Dual-Engineered Regulatory T Cell Therapy Product for Type 1 Diabetes with Enhanced Stability, Tissue Specificity, and Tunable IL-2 Signaling

Jennifer Yam[1], Hunter Kenyon Kellogg[1], Ashley Landuyt[1], Priya Saikumar[1], Marko Repic[1], Gene Uenishi[1], Soo Jung Yang[2], Emma Mortensen[2], Phillipe Kieffer-Kwon[1], Tiffany Chen[1], Jane Buckner[2], Tom Wickham[1], Karen Mueller[1]
[1]GentiBio, Cambridge, MA,[2]Benaroya Research Institute, Seattle, WA

Regulatory T cells (Tregs) play a vital role in natural immune regulation and the prevention of autoimmune disease. Impaired function of Tregs can lead to autoimmune or autoinflammatory conditions. In Type 1 Diabetes (T1D), pancreatic islet-specific effector T cells (Teffs) cause inflammation and destruction of beta islet cells, leading to hyperglycemia. The introduction of islet-specific Tregs has the potential to control and reverse inflammation. Current sorted Treg therapies face 3 challenges, i) unstable phenotype, ii) a lack of tissue specificity, and iii) lack of IL-2 support. GNTI-122, an autologous cell therapy for T1D, is a genome-engineered Treg (EngTreg) designed to address these challenges by stabilizing FOXP3 expression, expression of an islet antigen-specific TCR, and a chemically inducible IL-2 signaling complex (CISC). GNTI-122 is engineered from bulk CD4+ cells with CRISPR-Cas9 to knock-in an MND promoter which bypasses TSDR-mediated silencing and stabilizes FOXP3 expression. This imparts a robust Treg phenotype (CD25, CTLA4, EOS, CD39, CD27, TNFRII, and low CD127 and CD70) in comparison to mock engineered cells, proving that engineering of stable FOXP3 expression enhances Treg phenotype. Upon stimulation, GNTI-122 maintains low expression of IL-2 and IFN-y, and increased expression of LAP and GARP, providing evidence of Treg function. The islet antigen-specific TCR, IGRP305-TCR, is engineered into the TRAC locus while simultaneously knocking-out endogenous TCRalpha and ensuring tissue specificity. Upon stimulation through its TCR by its cognate peptide, GNTI-122 cells display potent immunosuppressive activity in direct and bystander suppression assays. Importantly, in a polyclonal suppression assay, GNTI-122 suppresses activation and proliferation of a polyclonal pool of Teffs specific to islet antigens isolated from patients with T1D. Antigen specificity enables distinct activation of GNTI-122, allowing targeted immune regulation.The selective enrichment of the dual engineered cells is enabled by the addition of rapamycin-activated, CISCb into the FOXP3 locus, and the CISCg into the TRAC locus, providing IL-2-like signaling in only the dual engineered cells. Following gene editing, selective IL-2 signaling via CISC enables enrichment of GNTI-122 to >90% purity in culture. Activation of CISC in combination with TCR stimulation enhances engraftment and persistence in vivo where IL-2 is scarce in the inflamed microenvironment of the pancreas. Engraftment studies in NSG mice show rapamycin dose-dependent increase in engraftment and persistence, supporting the use of rapamycin in vivo. Altogether, GNTI-122 overcomes the key limitations of sorted Treg therapy, demonstrating direct, bystander, and polyclonal suppression in vitro, while maintaining IL-2 signaling support. Pharmacodynamic, pharmacokinetic, and pre-clinical safety data, including efficacy of murine surrogate models in vivo, support further evaluation of GNTI-122 in clinical trials.

740 Generation of PSC-Derived Class I MHC-Null, Antigen-Specific, Mature, Cytotoxic T Cells Using an Engineered *In Vitro* Organoid Microenvironment

Patrick C. Chang[1], Xuegang Yuan[1], Alexandre Zampieri[1], Chloe Towns[1], Sang Pil Yoo[1], Claire Engstrom[1], Steven C. Tsai[2], Yuhua Zhu[1], Shawn Lopez[1], Christopher S. Seet[2], Amelie Montel-Hagen[1], Gay M. Crooks[1]
[1]Department of Pathology & Laboratory Medicine, David Geffen School of Medicine, UCLA, Los Angeles, CA,[2]Division of Hematology-Oncology, David Geffen School of Medicine, UCLA, Los Angeles, CA

Cell-based immunotherapies in which autologous T cells have been engineered to express chimeric antigen receptors **(CARs)** and antigen-specific T cell receptors **(TCRs)** have produced impressive clinical

responses. Despite producing curative results, widespread application of adoptive cell therapies is limited by the complex and costly manufacturing processes for delivering patient-specific treatments, and the variability in T cell composition from each patient. To overcome these constraints, development of "off-the-shelf" engineered T cell products has garnered increasing interest. However, the requirement for an allogeneic source with this approach presents two main barriers: donor T cell mediated alloreactivity (causing graft versus host disease [**GvHD**]), and host-mediated rejection of HLA-mismatched allogeneic donor cells. While manipulation of these allogeneic mechanisms via gene editing of healthy donor peripheral blood T cells has been pursued, current techniques do not guarantee complete ablation of endogenous TCRs, and the gene-editing process carries the risk of genomic translocations and deleterious off-target events. Human pluripotent stem cells (**PSCs**) are a promising alternative allogeneic source as they are an infinitely self-renewing, and are amenable to gene-editing approaches and cloning to address alloreactivity and host-mediated rejection. Here, we report the development of Class I MHC-null, antigen-specific, naïve CD8 T cells from gene-edited PSCs using the "Artificial Thymic Organoid" (**ATO**) system previously developed by our lab, which induces highly efficient and reproducible differentiation of mature, naïve T cells from PSC sources. To prevent alloreactive TCR generation, we deleted both recombination activation genes (***RAG1*** and ***RAG2***) via CRISPR/Cas9 to generate *RAG1*$^{-/-}$*RAG2*$^{-/-}$ double knockout (**DKO**) PSCs. As predicted, T cell development from DKO PSCs was arrested due to the loss of endogenous TCRs. To support positive selection in the absence of endogenously rearranged TCRs, DKO PSCs were transduced with a lentivirus to constitutively express the HLA-A*0201-restricted 1G4 TCR recognizing the tumor antigen NYESO, generating DKO+TCR PSCs. Naïve, antigen-restricted T cells were exclusively generated from 1G4 TCR-transduced **DKO+TCR** PSCs that endogenously expressed HLA-A*0201, demonstrating that positive selection in the ATO system is restricted to the cognate MHC of the 1G4 TCR. Subsequently, DKO+TCR PSCs were edited to eliminate surface expression of Class I MHC by deleting Beta-2-microglobulin (***B2M***) via CRISPR/Cas9 to generate *RAG1*$^{-/-}$*RAG2*$^{-/-}$*B2M*$^{-/-}$ triple knockout (**TKO+TCR**) PSCs. Full T cell differentiation, including positive selection, was achieved from TKO+TCR PSCs by engineering the stromal component of the ATO system, MS5 bone marrow stromal cells expressing human Delta-like-ligand 4 (***DLL4***), to provide the proper signals for positive selection, including human HLA-A*0201, the 1G4 TCR's cognate MHC, as well as human *B2M*. Edited, TKO T cells exhibited potent antigen-specific cytotoxicity *in vitro* as well as tumor control *in vivo* that was superior to unedited T cells due to the absence of TCR mispairing, confirmed through 10X TCR sequencing. Overall, these results demonstrate for the first time that not only stem cells but also the *in vitro* microenvironment can be modified to deliver the necessary signals for T cell development when expression of genes involved in alloreactive mechanisms are disrupted.

741 Generation of Functional CD8ab T Cells from iPSCs in a TCR-Signal Independent Manner via Supra-Physiological Notch Signaling Provided by DLL4/VCAM-Coupled Microbeads

Daniel Kirouac[1], Richard Carpendo[2], Alessia Pallaoro[2], Hiofan Hoi[2], Elham Afshinmanesh[2], Mark Ouellette[1], Cole Zmurchok[1], Avisek Deyati[1], Sidd Chandrasekaran[1], Valerie Wall[2], Steve Woodside[1], Deepika Rajesh[1], Emily Titus[3], Chris Bond[4]

[1]Systems Biology, Notch Therapeutics, Vancouver, BC, Canada,[2]Notch Therapeutics, Vancouver, BC, Canada,[3]Notch Therapeutics, Toronto, ON, Canada,[4]Notch Therapeutics, Seattle, WA

The use of clonally-derived, induced pluripotent stem cells (iPSCs) as starting material for therapeutic T cell manufacturing would overcome many limitations of autologous Chimeric Antigen Receptor T cell (CAR-T) therapies. Complex, multi-stage genome engineering, large batch production and rigorous lot testing could provide a consistent source of off-the-shelf, functionally enhanced T cell products. However, this vision cannot be realized using existing T cell differentiation platforms, which fail to present Notch ligands with the precision and intensity required to control T cell differentiation in scalable, suspension culture. Moreover, current technologies do not allow researchers to explore the quantiative relationship between Notch signaling intensity and cell differentiation. We have previously shown that VCAM synergizes with DLL4 to enhance Notch signalling and progenitor T cell differentiation. We have extended the utility of this discovery through the creation of DLL4/VCAM-conjugated, magnetic microbeads ("Engineered Thymic Niche" technology), enabling precise and temporal control of Notch signaling in suspension culture. iPSC-derived CD34+ cells cultured with varying amounts of DLL4/VCAM1 beads demonstrate dose-responsive activation of Notch gene expression (e.g., Notch1, DTX1, TCF7), resultant T lineage commitment (e.g. CD5, CD7 expression) and differentiation (e.g. CD4, CD8 expression). Analysis of single cell transcriptomes during canonical T cell development in the thymus reveals that Notch signal intensity peaks in CD4-CD8- double-negative (DN) cells, then declines as cells transition to TCR-signal dependence during maturation from CD4+CD8+ (double positive; DP) to CD4-CD8+ (single positive; SP) cells. We queried whether supra-physiological, sustained Notch signaling could bypass the requirement for TCR signaling and intermediate differentiation stages toward cytotoxic T cells. We find that such conditions result in the rapid generation of CD8ab+ cells, bypassing the necessity of TCR/CD3 signaling during canonical differentiation. Using an iPSC cell line with a CAR knocked in at the *TRAC* locus (and thereby TCR-deficient), we apply this approach to generate CAR-expressing, CD8ab+ functional T cells, capable of multiple rounds of in vitro tumor cell lysis comparable to primary T cells.

742 Engineering a Gene Circuit-Enabled Cell Therapy with a Tamoxifen Regulated Safety Switch for Inducible Cell Death in Human Pluripotent Stem Cells and Their Derivatives

Chew-Li Soh[1], Rebecca Cottman[2], Conor McAuliffe[1], Vanessa Johnson[2], Michelle Hung[2], Yin Yin Chong[2], Noah Jacobs-Rebhun[1], Cloe Grace[1], Jeffrey Levin[1], Eren Chu[2], Assen Roguev[2], Russell Gordley[2], Tim Lu[2], Mark Tomishima[1]

[1]BlueRock Therapeutics, New York, NY,[2]Senti Biosciences, South San Francisco, CA

Therapeutic cell products derived from human pluripotent stem cells (hPSCs) can be used to replace lost cells and therefore restore function and reverse disease for an array of clinically intractable conditions. While cell therapies have the potential to change the practice of medicine, all such "living" drugs carry potential risks. One safeguard against these risks is the implementation of a safety switch that can ablate transplanted cells from a patient if desired. We designed a novel gene circuit which functions as a Safety Switch regulated by tamoxifen, an FDA approved drug with extensive clinical history and ability to cross the blood-brain-barrier. The gene circuit-engineered Safety Switch is composed of a small molecule (SM) binding domain (ERT2) fused to Caspase-9 (Casp9) which dimerizes in the presence of tamoxifen metabolites, initiating the apoptotic pathway and cell death. To ensure the Safety Switch would be translatable to the clinic, we aimed to ensure the ERT2 SM binding domain would dimerize at concentrations of tamoxifen metabolites present in the brain at FDA-approved doses of tamoxifen. To address this, we computationally identified mutations within the SM binding region of ERT2 to build a large combinatorial mutant library. Screening of the combinatorial library produced hundreds of ERT2 mutants that were further evaluated for improved drug sensitivity in the context of synthetic transcription factor and activation of a reporter gene. Four representative engineered ERT2 mutants demonstrating improved sensitivity to tamoxifen metabolites (4-OHT and Endoxifen) were next tested in the context of the Safety Switch. All four engineered ERT2-Casp9 candidates showed greater than 95% killing efficiency after the addition of 1 μM 4-OHT, in HEK293T cells within 48 hours of induction. To maximize the expression of the Safety Switch gene circuit, we engineered it into hPSCs using the Sustained Transgene Expression Loci (STEL) platform for robust, stable, and ubiquitous expression of biological cargo. Briefly, the four engineered ERT2-Casp9 candidates were linked in-frame after the coding sequence of the endogenous *GAPDH* gene via a 2A peptide. Clonally derived *GAPDH::TamCasp9* hPSC lines demonstrated induced apoptosis after administration of the tamoxifen metabolites, 4-OHT and Endoxifen, at nanomolar concentrations. Here, we have demonstrated that hPSCs harboring a novel TamCasp9 gene circuit-engineered Safety Switch mechanism expressed robustly from the *GAPDH* locus can allow transplanted cells to be removed with pharmacologically relevant concentrations of tamoxifen metabolites.

743 Novel VLA-4 Inhibitors for HSPC Mobilization and Gene Therapy

Jingyu Xiang, Peter Ruminski, Michael Rettig, Stephanie Christ, Megh Singh, Ezhilarasi Chendamarai, Leah Gehrs, Darja Karpova, Julie Ritchey, John F. DiPersio

Medicine, Washington University School of Medicine, Saint Louis, MO

Background:Hematopoietic stem and progenitor cell (HSPC) mobilization regimens that are less toxic, more rapid and more potent than G-CSF and/or plerixafor are needed to improve transplant outcomes, reduce cost, shorten treatment times and facilitate gene therapy. We previously published that small molecule VLA-4 inhibitors (VLA-4i) induce rapid and reversible mobilization of murine HSPCs and are synergistic when combined with G-CSF, CXCR4 inhibitors (CXCR4i) and/or CXCR2 agonists. However, currently available VLA-4i don't have the appropriate combination of VLA-4 potency, aqueous solubility, bioavailability, and PK properties to be useful for HSPC mobilization. Here, we evaluated the efficacy of HSPC mobilization by novel VLA4i alone and in combination with CXCR4I for the purpose of gene therapy.Methods:Novel VLA-4i were synthesized and tested for potency using soluble VCAM-1 binding assays. VLA4i were then tested in mice and non-human primates (NHPs) alone or in combination with the CXCR4i plerixafor or BL-8040. HSPC mobilization was measured by flow cytometry (FACS) or Colony Forming Unit (CFU) assays. For competitive transplantation studies, mobilized CD45.1+ BALB/c mouse blood (10 uL) was injected into lethally irradiated CD45.2+ BALB/c recipients alongside $2.5x10^5$ CD45.2+ BALB/c BM cells (n=10/cohort). For the viral transduction experiment, mobilized CD45.1+ BALB/c HSPCs were transduced with lentivirus for GFP expression and injected into lethally irradiated CD45.2+ BALB/c recipients alongside CD45.2+ BM. HSPC engraftment and GFP transduction efficiency were monitored by FACS. Results:We developed novel VLA-4i by strategically attaching varied polyethylene glycol (PEG) chains to an optimized VLA4i binding core. Using mouse mobilization assays, we determined that a minimum PEG length of 24 units was required for extended HSPC mobilization. We then evaluated HSPC mobilization by WU-106 (VLA-4i with 24 PEG units) alone and in combination with plerixafor in NHPs. As expected, WU-106 alone was a weak mobilizing agent (**Fig. 1A**). Plerixafor alone was more potent and increased CD34+ counts 17-fold. The combination of plerixafor and WU-106 induced synergistic mobilization of HSPCs (50-100-fold; **Fig. 1A**). We next generated a longer PEG unit derivative of WU-106, named WU-125. WU-125 remained as potent as WU-106 at inhibiting VLA-4 and significantly extended murine HSPC mobilization both alone and when combined with plerixafor or BL-8040 (**Fig. 1B**). To explore if our VLA-4i + CXCR4i regimen represents an optimal graft source for gene therapy, we enriched murine HSPCs from the blood of mobilized mice by immunomagnetic selection, transduced them with GFP-containing lentivirus and injected them along with carrier BM into lethally irradiated congenic recipients. At 8 months post-transplant, we observed GFP+ cells among multiple lymphoid and myeloid cell lineages (**Fig. 1C**). This suggests that treatment with WU-106 + BL-8040mobilizes primitive HSPCs susceptible to gene therapy. Conclusion:We developed novel and potent VLA-4i that provide rapid and synergistic HSPC mobilization in combination with a CXCR4i. HSPCs mobilized with the combination of WU-106 + BL-8040 showed

efficient *ex vivo* viral transduction and stable long-term multilineage engraftment *in vivo*, which provides proof of concept that this approach could be used in gene editing therapy in the future.

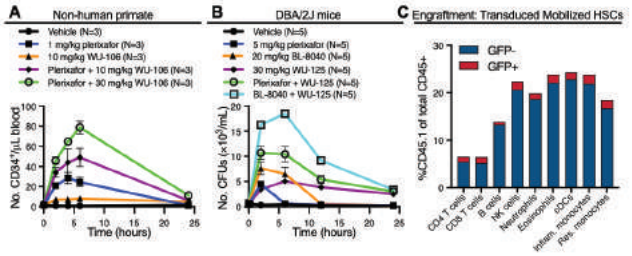


Fig. 1. HSPC mobilization and transduction. (**A**) NHPs were treated sequentially with the indicated regimens and the number of circulating CD34+ cells was determined over time by FACS. There was a 1-week washout period between each mobilization regimen. (**B**) Mice were treated as indicated and blood CFU numbers were determined. (**C**) Murine HSPCs harvested from the peripheral blood after treatment with WU-106 and BL-8040 were transduced ex vivo and transplanted into lethally irradiated congenic recipients. Engraftment of mobilized HSPCs was evaluated by flow cytometry 8 months after transplant.

744 Injectable Stem Cell Therapy Enabled by Microgels to Alleviate Discogenic Low Back Pain

Jacob Wechsler[1], Wensen Jiang[1], Giselle Kaneda[1], Lei Mou[2], Wei Huang[2], Thomas Spaeter[1], Julia Sheyn[1], Changlu Xu[3], Victoria Yu[1], Melissa Chavez[1], Chloe Castaneda[1], Ethan Ha[1], Wafa Tawackoli[4], Linda E. A. Kanim[5], Oksana Shelest[1], Hyun W. Bae[6], Dror Seliktar[7], Samad Ahadian[2], Mehmet R. Dokmeci[2], Ali Khademhosseini[2], Dmitriy Sheyn[8]

[1]Regenerative Medicine Institute, Cedars-Sinai Medical Center, Los Angeles, CA,[2]Terasaki Institute of Biomedical Innovation, Los Angeles, CA,[3]University of California at Riverside, Riverside, CA,[4]Department of Surgery, Cedars-Sinai Medical Center, Los Angeles, CA,[5]Orthopaedic Stem Cell Research Laboratory, Cedars-Sinai Medical Center, Los Angeles, CA,[6]Department of Orthopedics, Cedars-Sinai Medical Center, Los Angeles, CA,[7]Technion, Haifa, Israel,[8]Cedars-Sinai Medical Center, Los Angeles, CA

Chronic low back pain (LBP) affects over half a billion people worldwide and is commonly associated with intervertebral disc (IVD) degeneration. IVD regeneration remains an unmet clinical need, as current therapies such as surgical intervention and pain alleviation do not address the disease at its root cause - deterioration of the nucleus pulposus (NP) in inner core of the IVD. Notochordal cells (NCs) give rise to NP cells in development, have the potential to replenish NP cells and regenerate the IVD. NC are scarcely available in the adult but could be differentiated from induced pluripotent stem cells (iPSC). Our strategy is to develop an injectable cell therapy for LBP leveraging iPSC-derived NCs (iNCs) in combination with a cell delivery system based on hydrogel microparticles (microgels). The thermo-responsive hydrogels allow to encapsulate and precondition cells without introducing any cytotoxic crosslinker. The potency of this cell therapy was examined in vivo in a rat IVD degeneration model. The iPSCs were differentiated into iNCs using a previously published three-step process. The iNCs were encapsulated in fibrinogen-based thermo-responsive hydrogels in a microfluidic device at 10 million cells/ml gel. The microgels were purified to aqueous solutions for 7d (preconditioning). For the in vivo experiment, fluoroscopy-guided percutaneous needle injury was performed in rat lumbar discs (L4-5 & L5-6). After 2 weeks, iNC-loaded microgels were injected into the degenerated discs. The IVD height were evaluated using µCT and the discogenic pain was evaluated using biobehavioral tests. Our microfluidic device was designed and fabricated (Fig. 1A, B). The microgels have unified morphology and consistent cell density (Fig 1C, D). The diameter of the microgels was ~150µm in average after the purification (Fig 1E). Thermal gelation occurs around 21°C (Fig. 1F). The human cells encapsulated in microgel maintained comparable viability to the bulk hydrogel control (Fig. 1G). The 14d preconditioning of iNC-loaded microgels promoted ECM (Col2) deposition (Fig. 1H, I). In our needle-induced IVD degeneration rat model (Fig. 1J, K), the intradiscal injection of iNC-loaded microgels resulted in statistically higher cold hypersensitivity detected with acetone test (Fig 1L) and paw withdrawal pressure of rats compared to saline control (Fig. 1M), indicating less mechanical allodynia 2 weeks post treatment. The iNC-loaded group also showed increased IVD height at L4-L5 than saline control. The preconditioned iNC-loaded microgels showed positive effects in alleviating pain and regenerating IVDs as early as 2 weeks post-surgery. The high-quality injectable microgels and regenerative iNCs give hope for the clinical translation of minimally invasive cell therapies treating discogenic low back pain.

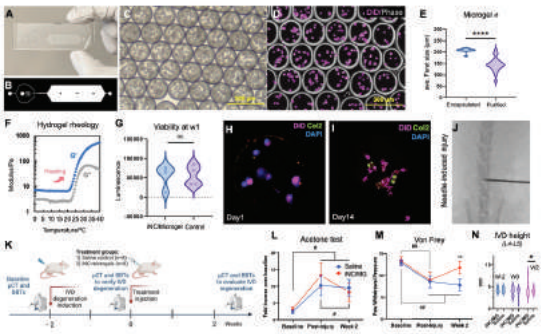

Fig. 1. Characterization and efficacy of iNC-loaded microgels as low back pain therapy. A, B. microfluidic device. **C.** Phase image of FF cell-loaded microgel in the device. **D.** Fluorescent image of DiD-labeled cells in FF microgels. **E.** microgel diameter calculated after encapsulation and after purification during which the oil is removed. **F.** Rheological property of FF microgel: storage modulus (G') and loss modulus (G") changed with temperature heating ramp. **G.** Viability of microgel-encapsulated cells after 1 week pre-conditioning. Cells in bulk gel served as a control group. Immunostaining of DiD labeled iNCs with Col2 antibodies on Day 1 after encapsulation (**H**) and on day 14 (**I**), imaged by confocal microscopy. **J.** Posterior view of 21G needle used to induce disc degeneration percutaneously. **K.** Experimental design of the in vivo study. The iNC-microgels were compared to Saline control. **G.** Acetone cold sensitivity and **H.** von Frey biobehavioral tests indicating nociceptive behaviors (n=7; *p<0.05, **p<0.01 between groups, ##p<0.01 compared to baseline). **N.** Disc height quantification at baseline (W-2), 2 weeks post injury (W0) and 2 weeks post treatment (W2).

745 Discovery of Key Transcriptional Regulators of Alloantigen-Inducible Tregs Used for Cell Therapy

Alma-Martina Cepika[1], Laura Amaya[1], Colin Waichler[1], Mansi Narula[1], Benjamin C. Thomas[1], Pauline P. Chen[1], Michelle M. Mantilla[1], Mara Pavel-Dinu[1], Robert Freeborn[1], Matthew H. Porteus[1], Rosa Bacchetta[1], Fabian Müller[2], William J. Greenleaf[1], Howard Y. Chang[1], Maria-Grazia Roncarolo[1]

[1]Stanford University, Stanford, CA,[2]Saarland University, Saarbrücken, Germany

Introduction: Graft-vs-host disease (GvHD) is the third leading cause of death in allogeneic hematopoietic stem cell transplantation (allo-HSCT). Unlike standard-of-care GvHD prophylaxis, alloantigen-specific (i.e., allospecific) type 1 regulatory T (Tr1) cells could prevent GvHD without impairing patient immunity against tumors and pathogens. Our allospecific Tr1 cells are already in two dose-escalating phase I/

II clinical trials, with promising early clinical results (ClinicalTrial.gov IDs NCT03198234 and NCT04640987). However, the current Tr1 manufacturing method results in a cell product with low Tr1 cell purity (≤10%), complicating dose escalation and data interpretation. We hypothesize that stable overexpression of a "master regulator" transcription factor (TF), which governs Tr1 cell differentiation, will result in a highly purified Tr1 cell product suitable for cell therapy. However, a master regulator TF(s) of human Tr1 cells is unknown. **Methods**: To identify the master regulator TF(s) of human Tr1 cells, we developed a functional epigenomics approach. We generated allospecific Tr1 cells (n=5) using the same protocol as is used for cGMP Tr1 production, then compared their epigenome (ATAC-seq) and transcriptome (RNA-seq) to 3 control T cell subsets. Differential TF binding site analysis, TF footprinting, and computational integration of Tr1 cell-specific epigenome and transcriptome to identify the domains of regulatory chromatin (known to be enriched for master regulator TFs) revealed six Tr1-specific TF candidates for the human Tr1 master regulator. The functional role of these candidate TFs in Tr1 cell differentiation was established by their CRISPR/Cas9-mediated knock-out (KO) or CRISPR-activation (CRISPRa) in parental CD4 T cells, which were then differentiated into allospecific Tr1 cell products. Finally, the Tr1 enrichment, phenotype, and function of TF-modified Tr1 products were compared to the wild-type controls. **Results**: Our functional epigenomics approach revealed new mechanistic insights into transcriptional regulation of human Tr1 cell differentiation and function. First, we established that EOMES (TF candidate #1), which is a proposed master regulator TF of allospecific murine Tr1 cells, plays no obvious role in the human allospecific Tr1 differentiation in our clinically-relevant model. Second, our CRISPRa experiments revealed that early activation of TF candidate #2, known to upregulate a key growth factor for human Tr1 differentiation, increases Tr1 cell frequency in allospecific Tr1 products by ≥ 50%. Finally, CRISPR KO of TF candidate #3 from parental CD4 T cells resulted in a significant reduction of Tr1 cell frequency in the allospecific Tr1 products, along with a significant reduction in the expression of co-inhibitory proteins LAG3 and CTLA-4. CTLA-4 is critical for the suppressive function of Tr1 cells; accordingly, Tr1 products without TF candidate #3 had a significantly diminished capacity to suppress effector T cell proliferation in response to alloantigen stimulation. **Conclusions**: We show that our functional epigenomics platform can be successfully applied to discover the function of human T cell TFs. We also show that TFs identified in murine Tr1 cells do not necessarily act the same in human Tr1 cells. Finally, we uncover two TFs that play key roles in differentiation and alloantigen-specific suppressive function of human Tr1 cells, which we will leverage to engineer new, purified Tr1 cell therapy.

746 A Study on Health Equity Challenges, Addressing Social Determinants of Health to Improve Access to Cell and Gene Therapies in US

Richard Rahul

Deloitte Consulting LLP, New York, NY

Introduction The evolving Cell and Gene Therapy (CGTx) marketplace is rapidly advancing, with multiple new therapies nearing commercialization or already commercially available. This rapid growth, however, sheds light on the multi-faceted, interconnected frictions within the current ecosystem that lead to CGTx patient access challenges, demonstrating how equity measures disparately affect access to CGTx. Through utilizing a framework that examines patient access to Zolgensma, an FDA approved Gene Therapy that treats Spinal Muscular Atrophy, the ways in which such equity measures affect patients in the CGTx community can be elucidated. We performed a waterfall analysis utilizing data from Komodo Prism, a database that covers 325M unique patient lives over 6+ year timeframes. We identified 1100 individuals within the population as individuals with SMA under the age of 2 years by filtering for SMA-specific ICD-10 diagnostic codes (Fig. 1). We then filtered this population by patients who underwent Zolgensma eligibility tests for AAV9 antibody levels, CVS, Creatinine, Troponin-I, and IFT (Fig. 1). The remaining patient population was then filtered to identify patients that received Zolgensma through J-code and CPT code filtering (Fig. 1). ResultsOf 1100 patients with SMA under 2 years of age, only 110 patients received Zolgensma representing a 90% decrease between eligible patients and patients that received therapy (Fig. 1). A 59% decrease of patient population was attributable to lack of confirmatory genetic testing leaving 451 patients remaining. From this population, a 47% decrease occurred when factoring in eligibility tests, leaving 238. Finally, of eligible patients, a 54% decrease occurred, and 110 patients of the original 1100 patient population received Zolgensma, representing 10% of the overall SMA patient population under 2 years of age (Fig. 1). DiscussionOur analysis demonstrates a significant decrease (90%) between patients in the SMA patient population under 2 years of age that are eligible to Zolgensma and the final patient population receiving the therapy. Through examining the different drop-off points within the waterfall analysis, it is likely that access and equability issues explain such a decrease and are especially troublesome for patients within the CGTx community. Patients that are originally identified as having Zolgensma face access issues in finding a timely diagnosis as mandatory newborn screening or public health services differs based on geographic region, socioeconomic status, and other demographic barriers. Furthermore, such a drop off can also be explained by lack of access to specialists that are qualified to diagnose and refer patients with rare conditions, and patients themselves face case navigation concerns while managing a complex qualification process for Zolgensma. Conclusion As the marketplace of CGTx evolves, innovative ways to improve equitable access must evolve alongside them. Individuals within the CGTx community such as knowledge leaders, manufacturers, insurance entities, and policy stakeholders need to determine unique and novel approaches to expanding access for all patients in the CGTx population.

747 Raw Material Variability in Biomanufacturing: A Case Study Using Poloxamer 188

Mahsa Mohiti-Asli

BASF Pharma Solutions, Tarrytown, NY

Gene therapy and cell-based products are growing rapidly and becoming a major part of the biotechnology industry. Meanwhile, this growth highlights several challenges in biomanufacturing, one of them being the raw material variability. This is a very critical bottleneck as it can lead to decreased productivity, process inconsistency and

compliance concerns. A critical material for cell shear protection, poloxamer 188, has a history of variability as the grades available in the marketplace had been optimized for other applications. BASF's poloxamer 188 product, Kolliphor® P188 Bio, is manufactured with the biomanufacturing industry in mind. To demonstrate minimal variability in and between batches, we tested samples of 2 batches of Kolliphor® P188 Bio in CHO-S and HEK293 cells. Samples from these lots were divided in 3 groups: early, middle and late samples depending on their drum number. We tested >>>1 samples of each designated type. Emulating a high shear environment, we recorded cell viability over 4 days of testing. Our data shows there is minimal change in overall cell performance between and within lots of Kolliphor® P188 Bio. Kolliphor® P188 Bio is a fit-for-function shear protectant offering shear protection while reducing variability in biomanufacturing processes.

748 Scalable Magnetic Bead-Based Cell Separation Technology for the Depletion of Receptor Positive Cells

Nils Brechmann[1], Kristofer Eriksson[1], Torbjörn Pettersson[2]

[1]MAGic Bioprocessing, Uppsala, Sweden,[2]Magic Bioprocessing, Uppsala, Sweden

Allogenic therapies provide the promising possibility for off-the-shelf cell therapies, which could help to lower production costs and ultimately the therapy costs. However, this is accompanied by a large array of challenges with regards to their manufacturing, such as the need for large production scales to realize the commercialization for off-the-shelf therapies. With growing scales, the isolation methods need to be efficient, simple, universal applicable and should provide functional and safe cells to support this. The sorting of cells, based on magnetic beads is well-established, e.g. magnetic activated cell sorting. But with the small size of magnetic cell sorting beads used nowadays, being significantly smaller than a cell, this provides the risk of internalization, non-uniform magnetic labelling and low mobility due to low magnetization of the cell. Therefore, today's magnetic beads are limited in terms of large production potential.We have previously shown that our large (≈ 100 µm) magnetic bead system MAGicbeads is highly gentle towards cells (Brechmann et al., 2021) and provided excellent scalability at pilot-scale for the purification of mAbs (Brechmann et al., 2019). In the present study we have developed a new scalable separation process based on flexible Protein A base conjugated magnetic agarose-based beads for the isolation of receptor positive cell subpopulations. This system provides flexible adjustments of the receptor recognising antibodies, potentially targeting different receptors at different stages throughout the manufacturing process. Evaluation of the sorting capabilities of this novel flexible sorting system with a model population of $HER2^+$ cells and hMSCs showed high depletion efficiencies of up to 91 % (Brechmann et al., 2022). With high biocompatibility, high robustness against mechanical stress and minimal unspecific binding. This can provide an important insight for further large-scale application using high magnetised large particles for the purification of cells prior to the application to patients.

749 A Novel Chemically-Defined Medium Supports Superior Cross-Platform T Cell Expansion

Chengkang Zhang, Karen Roderick, Amy Burkall, Elizabeth Kagan, Soumendra Chatterjee, Janet Sei, Tamara Laskowski, Tariq Haq, Alexis Bossie

Lonza Walkersville Inc, Rockville, MD

One of the weak links in the current good manufacturing process of genetically engineered T cells for adoptive cell therapy is the use of human serum. Human serum and derived components are expensive, potentially contain adventitious agents requiring stringent safety testing and may contain factors detrimental for T cell expansion. In addition, the performance of human serum may vary considerably from lot to lot, necessitating screening and stockpiling. The supply of high-quality human serum may be insufficient to meet global demand in the near future as more blockbuster adoptive T cell therapies are approved and become one pillar for modern medicine. We have developed a cell culture medium, which incorporates only recombinant proteins, is free of undefined animal origin components, and requires only the addition of cytokines and activation agents, thus streamlining the CAR-T cell therapy manufacturing process. This medium supports superior T cell expansion compared to other commercially available T cell expansion media which require supplementation with human serum. T cell manufacturing processes utilizing this chemically-defined medium represent an important step forward in making adoptive T cell therapy more consistent and scalable to better serve patients. The absence of human serum and human plasma-derived proteins during the activation, transfection or transduction, and expansion processes necessitates some changes in common cell culture procedures. Alternative handling practices to be considered when using a chemically-defined medium for CAR-T cell therapies will be discussed.

750 Modulation of Single-Cell Gene Expression and Cell Function in Evolving Manufacturing Processes for Clinical Trials with Enhanced-Affinity T-Cell Receptor T-Cell Therapy Targeting the MAGE-A4 Antigen in Solid Tumors

Sterenn Davis[1], William Spinner[1], Natalie Bath[1], Gareth Betts[1], Alicia Derrac Soria[1], Alasdair Gunn[1], Katerina Mardilovich[1], Emily Schmidt[1], Ian Donaldson[1], Bhavna Paratala[2], Ruoxi Wang[1], Chris Evans[2], Alex Tipping[1]

[1]Adaptimmune, Abingdon, Oxfordshire, United Kingdom,[2]Adaptimmune, Philadelphia, PA

Introduction: Affinity-enhanced T-cell receptor (TCR) T-cell therapies targeting the intracellular cancer testis antigen MAGE-A4 have shown encouraging results in adults with advanced solid cancers.[1,2] Here we explore how TCR T-cell therapy manufacturing process evolution may modulate the function of ADP-A2M4CD8, the next generation counterpart of afamitresgene autoleucel (afami-cel; formerly ADP-A2M4), using single-cell RNA sequencing (scRNA-seq) and in vitro functional assessment. **Methods:** Autologous T-cell products were

manufactured from patient leukapheresis material by transduction of a self-inactivating lentiviral vector expressing either a MAGE-A4-specific TCR alone (afami-cel), or the same MAGE-A4-specific TCR plus an additional CD8α co-receptor (ADP-A2M4CD8), followed by ex vivo expansion. Afami-cel T-cells were expanded for 11-15 days in a Xuri bioreactor. ADP-A2M4CD8 T-cells were expanded for 10 days in a G-Rex bioreactor, with or without addition of an AKT inhibitor. Transduced CD8+ T-cells were isolated from retains of afami-cel and ADP-A2M4CD8 products and evaluated for differences in gene expression profile (GEP) at the single-cell resolution (ie, via scRNA-seq). Transduced CD4+ T-cells from ADP-A2M4CD8 products were also profiled as they demonstrate increased tumor cell lysis via the CD8α receptor. All subsets were assessed for their capacity to directly lyse tumor cells in vitro. **Results:** In unsupervised analyses, transcriptional profiles of ADP-A2M4CD8 showed considerable variation between clinical trial participants, for whom these products were manufactured, and between manufacturing processes. A notable shift from the afami-cel GEP was observed in ADP-A2M4CD8 T-cells, which were manufactured using G-rex based ex vivo expansion. A novel cellular subset, with an apparently less cytotoxic GEP, was seen in transduced T-cells from ADP-A2M4CD8 that was not seen in afami-cel. In addition to this novel subset, ADP-A2M4CD8 contained variable proportions of a CD8+ T-cell subtype prevalent in afami-cel products. This effect was enhanced by the inclusion of an AKT inhibitor during ex vivo expansion. These gene expression changes were accompanied by a delay in cytotoxicity with ultimately similar capacity to lyse target cells in vitro, which might suggest production of less differentiated cells. Translational correlation with the prevalence of these subsets will be discussed, along with the possible implications of these data related to the mechanism of action of afami-cel and ADP-A2M4CD8. **Conclusions:** Whole-transcriptome, single-cell investigation of the cellular subsets produced during manufacturing of afami-cel and ADP-A2M4CD8 indicate that infusion of cells with a less cytotoxic GEP does not prevent broad anti-tumor efficacy and may correspond with beneficial characteristics. 1. Van Tine BA, et al. Paper 61 presented at: CTOS 2022; Vancouver, BC, Canada. 2. Hong DS, et al. Ann Oncol. 2022;33 (suppl_7): S331.

751 Pre-Clinical Development of CT-1119, a Mesothelin-Targeting Chimeric Antigen Receptor Macrophage

Nicholas R. Anderson, Brinda Shah, Alison Worth, Rashid Gabbasov, Brett Menchel, Kerri Ciccaglione, Daniel Blumenthal, Stefano Pierini, Sabrina Ceeraz DeLong, Sascha Abramson, Thomas Condamine, Michael Klichinsky

Carisma Therapeutics, Philadelphia, PA

The immunosuppressive characteristics of the tumor microenvironment (TME) include the exclusion of T cells from the tumor and the surrounding stroma. Myeloid cells such as monocytes and macrophages, however, are actively recruited to the TME. Chimeric antigen macrophages (CAR-M) infiltrate the TME and exert targeted effector function, including phagocytosing tumor cells, activating the TME, and priming a broad anti-tumor adaptive immune response via T cell recruitment and antigen presentation. Previously, we developed CT-0508, a HER2-targeted CAR-M, which showed efficacy in a variety of pre-clinical models and is currently in a Phase I clinical trial for patients with HER2+ solid tumors. Mesothelin is a tumor associated antigen which is overexpressed in a wide variety of solid tumors, including lung, pancreatic, and ovarian cancers. CT-1119 was generated using the chimeric adenoviral vector Ad5f35 to express a CAR containing a fully human scFv targeting an epitope on the tumor associated antigen mesothelin. We evaluated its activity using both *in vitro* cell-based assays and *in vivo* xenograft tumor models. CT-1119 was highly viable with durable expression of the CAR. Importantly, the Ad5f35 vector yielded macrophages which were M1 (pro-inflammatory) polarized and resistant to re-polarization by M2 (pro-tumor) cytokines. Exposure to antigen amplified this effect with further down-regulation of M2 markers following stimulation. CT-1119 phagocytosed the A549 lung adenocarcinoma and MES-OV ovarian cystadenocarcinoma cell lines in an antigen-dependent manner and killed these cell lines *in vitro* in an antigen dependent manner. Engagement of the CAR yielded the release of pro-inflammatory cytokines such as TNFα in a dose-dependent manner in both cell-free and cell-based assays. CT-1119 significantly reduced tumor burden as measured by bioluminescent imaging in a murine xenograft model of lung cancer. In addition, Ad5f35 was utilized to generate functional anti-mesothelin CAR monocytes in a rapid single day process, yielding a population of myeloid progenitors restricted to M1-macrophage differentiation. In summary, these results show that the autologous human anti-mesothelin CAR-M are a targeted cell therapy capable of inducing a multi-modal anti-tumor mechanism of action.

752 Automated Perfusion-Based, Hollow-Fiber Bioreactor Supports Scalable T Cell Expansion

Nathan Frank, Mindy Miller, Dalip Sethi

Research and Development, Terumo Blood and Cell Technologies, Lakewood, CO

The Quantum Cell Expansion System is a high-performing, automated platform for manufacturing both adherent and suspension cells. Quantum Flex is the next-generation device that features enhancements including a PC-based cell processing application used to create protocols, monitor runs in real-time, and manage a fleet of up to 100 devices. Quantum Flex also supports cell expansions on a small-scale bioreactor that can be used for process development and cell manufacturing from the low-quantity starting material. In this study, T cells were grown in both small and standard-size bioreactors utilizing different types of media. Both bioreactors support expansions with high viability, high yields, and desired phenotypes such as Tcm and Tscm while ensuring T cell exhaustion is minimal. New, non-DEHP disposables include media bags that have two ports, allowing for unique media handling strategies that reduce cost and reagent usage. Standard and small bioreactor expansions used less than 5 and 1.5 liters of complete media, respectively. Moreover, the small bioreactor can generate an autologous T cell dose of over 3B Cells with a starting seed of just 1M cells. The flexibility of Quantum Flex along with the small bioreactor allows scaling at any point of the manufacturing process while ensuring the base technology and expansion platform are kept consistent.

753 Spinner Flask Modelling of Wave-Style Bioreactors Enables Suspension-Phase Cell Culture Process Development of Allogeneic CAR-NK Cell Therapies

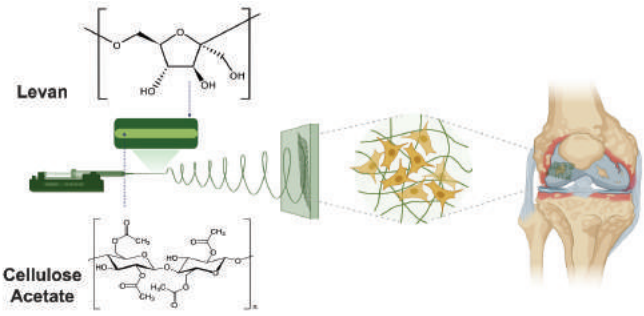
Mark A. Omobono, Billy Blanco, Krista Daniel, Joseph D. Gold, Priya Khurana, Beatriz Marques, Finola Moore, Adriana Rivera, Meghan Walsh, Keith Wong
Catamaran Bio, Boston, MA

Multiplex-engineered natural killer (NK) cells expressing therapeutic proteins are an exciting new modality in the cell therapy space with potential to be used as off-the-shelf allogeneic therapies for solid and hematologic malignancies. Clinical application of allogeneic NK cells requires a high-yield process that is most efficiently achieved using a suspension cell culture manufacturing platform; in the cell therapy field, wave-style bioreactors are widely used for this purpose. However, early process development of cell therapy manufacturing processes is commonly executed in static cultures, which can produce phenotypically and functionally distinct cells from suspension cultures. Static cultures are additionally limited from approaching suspension culture-specific variables, such as volumetric cell density control, and furthermore omit modeling of a static-suspension hybrid production process. ¶ As a result of these shortcomings, we developed a 150mL spinner flask format to better model a suspension cell culture environment. Two distinct CAR-NK products, CAT-179 and CAT-248, were produced in three different culture systems: 150mL spinner flasks, 1L static cultures and 2L wave-style bioreactors. Cells produced in spinner flasks showed comparable expansion profiles and transgene expression to wave-style bioreactors, while static cultures displayed increased cell yield but lower transgene expression, respectively. *In vitro* analysis of samples from the three culture systems revealed that cells produced in spinner flasks displayed a similar phenotype, cytotoxicity, and cytokine release level to those cells produced in wave-style bioreactors, compared to cells expanded in static flasks. ¶We next used the spinner flask model to optimize the timing of seeding a static co-culture of irradiated feeder cells (irrK562) and engineered NK cells into a wave bioreactor. We found that a static culture period of 4 days after irrK562 seeding was required to maximize cell yield, but the increased static culture period decreased expression of engineered transgenes. Use of the model revealed that the optimization of this parameter is critical to maximizing the yield of potent drug products in the CAT-248 process. ¶In summary, our data demonstrates proof of concept for the use of spinner flasks for culturing NK cells, providing a small-scale platform to model a wave-style suspension culture process more accurately. Use of this model will expedite scale-up process development as we pursue our clinical goals, shortening the path to clinical readiness and supplying a more complete data package in support of the clinical manufacturing of multiplex-engineered NK cells for solid tumor applications.

754 Bioadhesive Levan Based Nanofiber Using Coaxial Electrospinning Techniques for Cell-Based Tissue Engineering Therapies

Eunhyun Ji[1], Jae Kyeong Lee[2], Jeong Hyun Seo[2], Kye Il Joo[1]
[1]Ewha Womans University, Seoul, Korea, Republic of,[2]Yeungnam University, Gyeongsan, Korea, Republic of

Electrospun nanofibers have been widely used for tissue engineering scaffolds because they can function as an extracellular matrix (ECM), which plays a significant role in cell proliferation, adhesion, and differentiation. Furthermore, they also enable modification to improve the functional properties of cells. However, the issues of weak mechanical strength and biological functions of electrospun nanofiber scaffolds hinder their range of practical applications. In this study, we established a uniform levan-based core shell nanofiber scaffolding using the co-axial electrospinning technique. The coaxial nanofiber matrices with levan in the shell and cellulose acetate (CA) in the core exhibited both highly reinforced mechanical properties and adhesive strength. Moreover, cells were observed to show improved attachment and proliferation on the bioadhesive composite nanofibers, particularly in terms of enhanced interaction with their structure during the early adhesion process. The biocompatible coaxial electrospun nanofibers also revealed suitable biodegradability properties and a lack of cytotoxic effects. This study also aimed to incorporate mesenchymal stem cells into nanofiber scaffolds fabricated by coaxial electrospinning for cell-based tissue engineering therapies. Bone marrow-derived mesenchymal stem cells (BM-MSCs) were cultured on levan-based nanofiberous architecture and we evaluated the osteogenic and chondrogenic differentiation ability of BM-MSCs *in vitro* using staining methods. Compared to the non-nanofiber scaffolds, BM-MSCs on nanofiber scaffolds exhibited enhanced osteogenesis and chondrogenesis by alizarin red staining and alcian blue staining, respectively. These results indicate that levan-based nanofiber architecture has the potential for delivering scaffolds to support BM-MSC's differentiability. Our results therefore suggest the application of the levan/CA composite nanofibers as an ECM in biomedical and tissue regenerative medicine applications.



755 Investigating Whole Blood as a Starting Material for CAR-T Cell Manufacturing

Roshini Traynor[1], Bella A. Vignola[1], Hannah Song[1], Sarmila Sarkar[1], Sarah Underwood[1], Michaela Prochazkova[1], Yihua Cai[1], Rongye Shi[1], Ping Jin[1], Robert Somerville[1], David F. Stroncek[1], Nirali Shah[2], Steven Highfill[1]

[1]Center for Cellular Engineering, Dept. of Transfusion Medicine, National Institutes of Health, Bethesda, MD,[2]Pediatric Oncology Branch, National Cancer institute, National Institutes of Health, Bethesda, MD

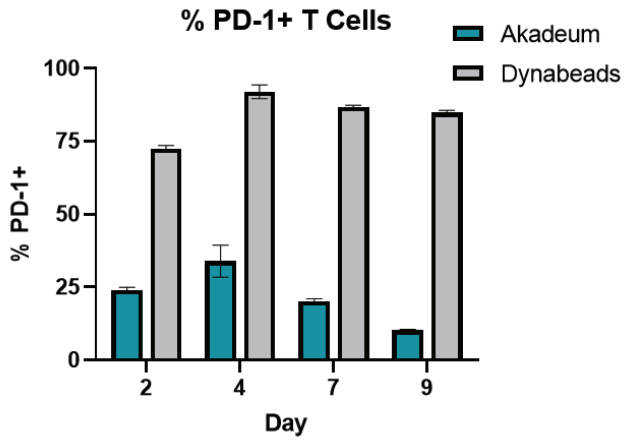
Background: Chimeric antigen receptor T cells (CAR-T) have revolutionized the treatment of certain types of cancers. T cells are typically collected from patients via mononuclear cell apheresis, a long process that isolates designated cells while returning remaining blood components back to the patient. Those in need of T cell therapy have to undergo this process, and often have a central line catheter inserted into their chest/groin area when profound veins aren't present. This is typically more challenging and can be painful for pediatric patients. In contrast, whole blood collection is a routine process that can be done anywhere and does not require specialty apheresis collection centers. Our goal in investigating whole blood as a starting material for CAR-T manufacturing is to examine the phenotypic and functional characteristics of CAR T-cells manufactured in this manner, and determine if whole blood is a suitable alternative to apheresis. **Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from whole blood via a closed-system, GMP compliant process using the Sepax (Cytiva). Whole blood samples were collected from eight healthy donors, including one donor who provided an apheresis and whole blood sample as a direct comparison. Isolated PBMCs were then were expanded and transduced with clinical-grade lentiviral vector encoding CD19/CD22 bispecific CAR using a fully-closed and GMP-compliant process, then cryopreserved on day 7. CAR-Ts were thawed and examined for phenotypic and functional properties. **RESULTS:** From a minimum of 29 mL of whole blood and 5-10x10^6starting CD3+ cells, we achieved a median day 7 T-cell yield of 105x10^6 (range 61 x10^6-188 x10^6) with 66% mean transduction efficiency, ultimately producing a median of 69.3 x10^6 transduced CAR-T cells (range 40.3 x10^6-124 x10^6). An ongoing clinical trial at the NIH Clinical Center utilizing the same CAR tested here (clinicaltrials.gov NCT03448393) has a safe and effective dose of 3x10^6 cells/ kg with an average patient weight of 60 kg. We show here that this therapeutic dose is attainable with a whole blood starting product given the scalability of the system and the fact that we can safely draw larger volumes of blood. Flow cytometry was performed to analyze the differentiation markers CCR7, CD45RA, and CD62L which showed T cell subtypes to be primarily mixed phenotype of CD45RA+CCR7- terminal effectors with high expression of CD62L, a marker of stem/central memory phenotype. High expression of CD25 and PD-1 (>50%) showed T cell activation with no more than 5-8% expression of exhaustion factor Lag3. CD19/22 CAR-T cells were incubated with GFP Nalm-6 ALL cells and Annexin V red apoptotic dye. We observed a rise in apoptosis with a simultaneous decrease in GFP Nalm-6 ALL fluorescence denoting tumor death, and targeted killing by CD19/22 CAR-T cells. Ongoing experiments are examining cytokine secretion using supernatants collected from CD19/22 transduced CAR-T cells co-cultured with Nalm-6 tumor cells to monitor levels of IFN-γ, TNF-α and IL-2. In conclusion, therapeutically relevant doses of CD19/CD22 CAR-T cells can be successfully manufactured from whole blood and we have shown that these cells exhibit high functional activity with targeted specificity.

756 Buoyant Microbubble-Based T Cell Activation Results in Significantly Reduced T Cell Exhaustion Profile

Edward Grimley, Tiffany Snow, Jon Roussey, Chia J. Ku, Maureen Carey, Jesse Chen, Bill Lloyd, Brittany Macintyre, Jason S. Ellis, Crisha Barrett, Casey J. Wegner, Brandon H. McNaughton

Akadeum Life Sciences, Ann Arbor, MI

Advanced therapy medicinal products (TMPs) such as Chimeric antigen receptor T cell (CAR-T) therapy have proven clinical efficacy. The ever-increasing number of clinical programs demonstrates continued enthusiasm for these life-saving treatments. A critical early step in the manufacturing of CAR-T cells is the co-stimulation of T cells. Traditionally, the stimulation reagents utilized for the activation of T cells were soluble CD3 and CD28 antibodies paired with accessory cells such as antigen-presenting cells (APCs). The activation resulting from this method was often variable and dependent on the quality of cells used. More recently activation of T cells has been achieved using iron beads or iron nano-matrices coated with CD3 and CD28 antibodies. While these methods result in a high degree of activation and expansion, they force the T cells into prolonged and continuous stimulation which leads to a strong increase in exhaustion markers such as PD-1, LAG-3, and TIM-3. Since exhausted CAR-T cells may result in lower efficacy, we investigated an activation workflow using buoyancy activated cell sorting (BACS™) microbubbles. A process that combines selection, activation, and expansion into a single workflow powered by BACS microbubbles is presented in this study. Due to the natural buoyancy of the microbubbles, activation and expansion take place at the top surface of the culture vessel. As the stimulated T cells divide, daughter cells dissociate from the microbubbles and settle at the bottom surface of the culture vessel where they are no longer in contact with the activation signals. This separation from the activation signals prevents overstimulation and results in a 2-fold lower expression of exhaustion markers relative to the industry-standard activation methods - only 25-30% PD-1+ T cell when microbubbles are used compared to over 90% when iron particle-based methods are used. CD3/CD28 microbubbles reduce the expression of exhaustion markers without compromising T cell activation as evidenced by the rapid upregulation of CD25 and other standard activation markers. Additionally, buoyant activation using microbubbles yield enhanced effector T cell populations and industry standard expansion kinetics. Taken together, these data show that our microbubble-based workflow provides improvements to all of the critical aspects of CAR T cell generation while eliminating many of the most significant hurdles.



757 Process Development for Efficient CAR T Cell Manufacturing Using a Closed Instrument Workflow

Yongchang Ji[1], Mina Ahmadi[1], Jason Isaacson[2], Gertrude Nonterah[1], Xavier De Mollerat Du Jeu[1]

[1]Cell Therapy Innovations, Thermo Fisher Scientific, Carlsbad, CA,[2]Cell Therapy Innovations, ThermoFisher, Carlsbad, CA

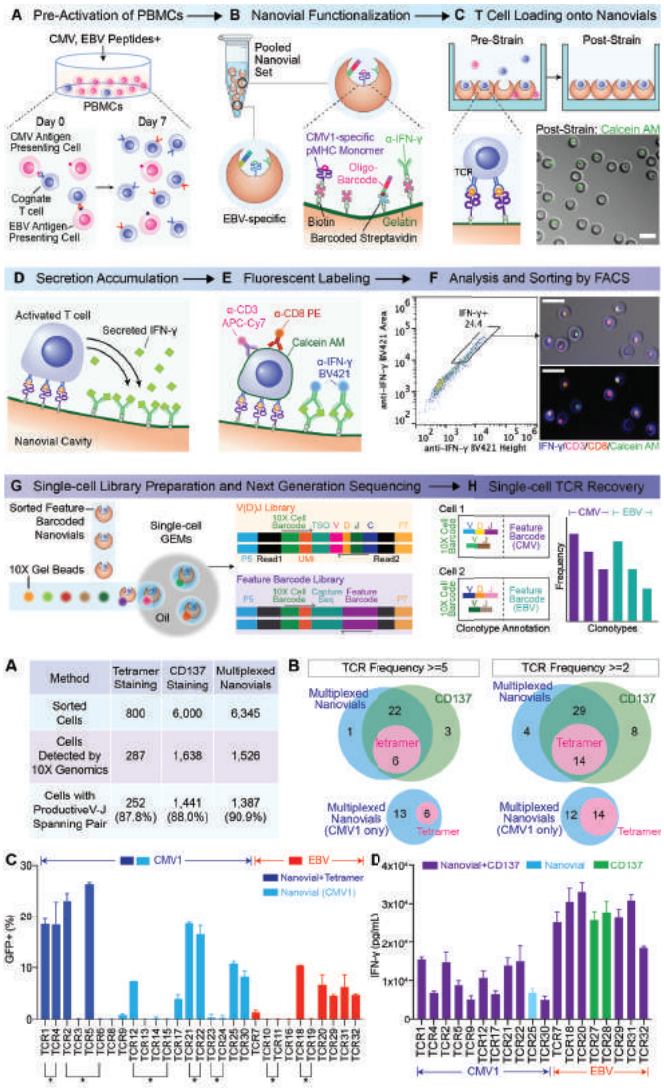
Over the last decade, researchers have demonstrated how (CAR) T cells can be effective in treating several devastating and often fatal cancers. CAR T cell therapies also show promising results for long-term antineoplastic effects, keeping patients in remission longer with the potential promise of a complete cure. Yet, current T cell therapy manufacturing processes are complex, manual, and labor-intensive. This impacts regulatory compliance and prolongs timelines to get therapies to patients. Furthermore, this could raise the price of CAR T cell therapy, limiting patient access to potentially life-saving treatment. A complete, closed, automated CAR T cell therapy workflow could improve consistency and safety of the CAR T cell therapies and reduce their costs. Our series of closed, modular instruments can be both physically and digitally integrated in a complete, automated, end-to-end CAR T cell manufacturing process. To do this efficiently, we have had to optimize the process for each of our modular instruments. Here, we show process optimization data for each of our modular instruments including a demonstration of how a closed, physical integration of two of our instruments—the Gibco™ CTS™ Rotea Counterflow Centrifugation System and the Gibco™ CTS™ Xenon Electroporation System—can lead to the efficient manufacturing of CAR T cells.

758 Defining T Cell Receptor Repertoires Using Nanovial-Based Affinity and Functional Screening

Doyeon Koo[1], Zhiyuan Mao[2], Robert Dimatteo[3], Natalie Tsubamoto[1], Miyako Noguchi[4], Jami McLaughlin[4], Wendy Tran[4], Sohyung Lee[3], Donghui Cheng[5], Joseph de Rutte[6], Giselle Burton Sojo[4], Owen Witte[2], Dino Di Carlo[1,6]

[1]Bioengineering, University of California Los Angeles, Los Angeles, CA,[2]Molecular and Medical Pharmacology David Geffen School of Medicine, University of California Los Angeles, Los Angeles, CA,[3]Chemical and Biomolecular Engineering, University of California Los Angeles, Los Angeles, CA,[4]Microbiology, Immunology and Molecular Genetics, University of California Los Angeles, Los Angeles, CA,[5]Eli and Edythe Broad Center of Regenerative Medicine and Stem Cell Research, University of California Los Angeles, Los Angeles, CA,[6]Partillion Bioscience, Los Angeles, CA

There have been encouraging successes in the use of engineered T cell-based therapies, including T cell receptor (TCR) immunotherapy, in treating cancer. However, one technical hurdle for developing effective TCR immunotherapy is to identify reactive TCRs from diverse sequence repertoires (10^8-10^{20}) that recognize targets with sufficient affinity and potency to induce apoptosis or activate other immune cells by secreting communication factors, such as cytokines. Current phenotyping approaches focus on affinity-based screening of differentially expressed surface receptors which fail to describe their functional potency or mimic the immune synapse of an antigen presenting cell. An ideal technology would combine antigen-specific enrichment and activation-based screening to achieve highly specific identification of functional TCR sequences along with knowledge of their cognate target epitopes. Here, we leverage cavity-containing hydrogel microparticles, called "nanovials", to achieve combined antigen-specific capture and activation-based high-throughput functional analysis and sorting of T cells based on secreted cytokines (Figure 1A). Each nanovial acts as both an artificial antigen-presenting cell, presenting millions of peptide-major histocompatibility complex (pMHC) molecules within the cavity creating a high avidity effect to capture and activate T cells even with low affinity TCRs, and as a capture site for secreted cytokines. Live cells on nanovials are sorted based on CD3 and CD8 expression and IFN-γ secretion, followed by single-cell sequencing to construct a TCR library with matching αβ-chains. In comparison to other screening approaches (MHC tetramer and CD137 staining), nanovials recovered the highest fraction of cells with a productive V-J spanning pair (90.9%) (Figure 2A). The nanovial workflow recovered significantly more clones (29) than gold standard tetramer staining (6) (Figure 2B). By labeling nanovials having different pMHCs with unique oligonucleotide-barcodes we could link TCR sequence to targets with 100% accuracy. A majority (78%) of clonotypes recovered using the nanovial technique were found to be reactive upon re-expression into NFAT-Jurkat GFP reporter cells and lead to functional secretion of IFN-γ when transduced into primary T cells (Figure 2C-D). Multi-parametric analysis of nanovials identified with high specificity an expanded repertoire of functional TCRs targeting viral antigens compared to standard techniques.



Method	Tetramer Staining	CD137 Staining	Multiplexed Nanovials
Sorted Cells	800	6,000	6,345
Cells Detected by 10X Genomics	287	1,638	1,526
Cells with ProductiveV-J Spanning Pair	252 (87.8%)	1,441 (88.0%)	1,387 (90.9%)

759 Engineering Therapeutic Cells through Rewiring of the miRNA Network

Vlad Seitan

Laverock Therapeutics, Stevenage, United Kingdom

To meet their full therapeutic potential, cell therapies need to overcome significant challenges relating to efficacy, safety, and cost. Clearing these hurdles requires increasingly complex cellular engineering. Gene editing approaches have provided much needed tools to genetically engineer therapeutic cells, but they mainly enable constitutive changes in gene expression with limited tuning capacity (e.g., gene KO). Gene silencing approaches based on RNA interference (RNAi) allow temporal and cell type-specific regulation of gene silencing activity, but current approaches such as synthetic siRNA or transgenic shRNA, are notoriously difficult to control. siRNA is intrinsically transient, and shRNA transgenes can be either epigenetically inactivated or result in supra-physiological expression and significant off-target effects. There is a need for new tools that can enable stable, tunable and programmable gene silencing with minimal or no off-target effects. We have established a new programmable gene silencing technology called GEiGS (Gene Editing-induced Gene Silencing) that overcomes many of the limitations of current approaches. GEiGS is a new way of leveraging the RNAi pathway in mammalian cells, by repurposing endogenous miRNA genes to express new target-specific siRNAs. Instead of inducing silencing through the delivery of synthetic oligos (siRNA) or through exogenous transgenes (shRNA), GEiGS works by introducing specific monoallelic gene edits into endogenous miRNA genes, re-coding their pre-miRNA (hairpin) region so that instead of the original physiological miRNA, they express a new siRNA directed against the target of interest. By exploiting redundancies in the miRNA network (editing individual members within families of related miRNAs) GEiGS can re-wire miRNA gene activity without detrimental loss-of-function effects. Repurposing endogenous miRNA genes as siRNA vectors has several significant advantages over existing gene silencing approaches: 1) minimal genome edits, no exogenous regulatory elements or transgenes; 2) stable and tunable silencing activity - endogenous miRNA genes have reproducible expression protected from epigenetic inactivation. Because the expression of the repurposed miRNA directly predicts the abundance (and hence activity) of the GEiGS siRNA, silencing can be dialled up or down through the choice of repurposed miRNA; 3) programmable silencing. Because miRNA expression patterns change in predictable manner during cellular differentiation or in response to changes in the cell state, these dynamic changes can be leveraged to program gene silencing to be induced 'in the right place, at the right time, and in the right cell type'; 4) specificity - gene silencing occurs with minimal or no off-target effects. We deployed GEiGS in human iPS cells to show it can specifically silence B2M, a component of the MHC-I complex and a target relevant for the generation of hypoimmunogenic cells for allogeneic cell therapies. We show that GEiGS is a very effective gene silencing approach that reproducibly allows stable homogenous silencing of MHC-I over a broad range of expression. By repurposing miRNAs with different levels of physiological expression, we were able to precisely tune MHC-I, ranging from near-complete silencing to distinct intermediate expression levels. Strikingly, GEiGS was able to maintain silencing even when MHC-I was induced by more than 10-fold following IFNg treatment. Importantly, whole transcriptomics analyses revealed that in contrast to siRNA and shRNA, which can show extensive off-target effects, GEiGS is very specific, showing no evident off-target effects associated either with the loss of the redirected miRNA genes or with silencing of unintended targets. This establishes GEiGS as a powerful new approach to gene silencing, and to our knowledge represents the first demonstration that endogenous human miRNA genes can be successfully re-wired to achieve specific regulation of new target genes.

760 Advancements in Manufacturing of CD8-Targeted Fusosomes Enhance Transduction of Resting T Cells *In Vitro* and *In Vivo*

Kyle Trudeau[1], Misha Shamashkin[1], Xiao Shi[1], Tejsi Dhameliya[1], Joanna Donatelli[1], Derek Smith[1], Maxwell Lloyd[1], Noelle Colant[1], Kaely Gallagher[1], Andrew Englehart[1], Amey Gaikwad[1], Sanket Phadke[1], Alison Kleinfeld[1], Michael Leahy[1], Nicholas Mozdzierz[1], Yonatan Lipsitz[1], Emelia Ansu-Gyeabourh[1], Kelan Hlavaty[1], Tom Kowski[1], Emerson Moore[1], Andre DeGroot[1], Matthew Scott-Skandera[1], Stephanie Riofrio[1], Mike DeCosta[1], Patricia Cruite[2], Shirisha Amatya[1], Neal Van Hoeven[1], Jesse Green[1], Kutlu Elpek[1], Albert Ruzo[1], Jagesh Shah[1], Athena Wong[1], Adam Charlton[1]

[1]Sana Biotechnology, Seattle, WA,[2]Sana Biotechnology -, Seattle, WA

Sana is currently developing a CD8-targeted fusosome to potentially enable *in vivo* CAR-T therapy. Previously, we have demonstrated specific delivery of a CD19CAR transgene to CD8-positive T cells *in vivo* with a CD8-targeted fusosome based on an integrating lentiviral vector, which facilitates potent tumor killing in mice and B cell depletion in NHPs. Production of high potency fusosomes is important to deliver a sufficient dose in clinical trials in patients. Here, we describe end-to-end advancements, including improvements to the producer cell line, fusosome composition, and downstream processing, enabling improved potency and reduced impurities for CD8-targeted fusosomes. To establish a producer cell line for Sana's fusosome manufacturing platform, we adapted a cell line to serum-free and suspension growth, followed by single cell cloning. Suspension clones were screened for productivity of CD8-targeted fusosomes that carry a CD19CAR transgene. The top clones were further selected for growth and morphology. The most productive clones yielded up to 8-fold higher titer and improved growth relative to the control cell line. Our retargeted fusogen system is derived from a paramyxovirus family where two proteins, G and F, are required for particle attachment and fusion, respectively. Optimizing the G levels for CD8-targeted fusogen increased G density and proportion of complete particles (increase to 74% complete vs. 44% without optimized G levels). Utilizing the new producer cell clone and optimized G levels led to a 5-fold increase in functional titer per liter of culture and a doubling of infectivity for the crude material. Process advancements to the downstream clarification and filtration steps were also implemented to improve potency and purity of the final fusosome formulation. These changes increased the yield of active fusosomes 6-fold and process recoveries were doubled, yielding over 10 times more active fusosomes per batch compared to the initial process. The infectivity ratio improved 7-fold, while host cell protein and DNA were reduced by 10-fold and 1000-fold, respectively. The synergy of these updated downstream steps with producer cell and optimized G level advancements enabled formulations with over 50 times higher functional titers; potentially increasing doses delivered per manufacturing run and potentially lower dosing volume. CD8-targeted fusosomes with CD19CAR transgene made using these improvements in the manufacturing process significantly outperformed fusosomes made using the initial process with respect to transduction of resting T cells *in vitro* and *in vivo*. Critically, the specificity for CD8-positive cells was comparable or improved with fusosomes made with the improved process as compared to the initial process. In summary, we have shown that optimizing aspects of the manufacturing process for CD8-targeted fusosomes results in significantly higher titers, reduced impurities, and more potent delivery to resting T cells *in vitro* and *in vivo*.

761 Multiplex Cell Engineering of Next Generation Chimeric Antigen Receptor T Cells with Functional Silencing of Six Target Molecules

Antonija Sakic, Marine Mansuy, Benedicte Ponsard, Vincent Blancheteau, Ines Lanz, Yasmine Genolet, Bryan Bourrat, Ophelie Cherpin, Sten Ilmjärv, Audrey Roussel-Gervais, Marco Alessandrini

Antion Biosciences, Geneva, Switzerland

Introduction: Chimeric antigen receptor (CAR) T-cell therapy is an established form of treatment for hematological malignancies. However, key challenges still remain, including a lack of efficacy against solid tumors and limited accessibility to these treatments. To overcome this, the need to multiplex engineer next generation CAR T-cells is essential, such that they can be provided as off-the-shelf (allogenic) therapies, capable of durable treatment response. The latter depends largely on the persistence of CAR T-cells, which not only relies on their fitness (continued functional activity), but also the ability to avoid rejection by the patient's immune system. We have developed an efficient strategy to create a next generation of CAR T-cells using a novel bimodal gene construct (miCAR) for simultaneous CAR expression and microRNA (miRNA) mediated gene silencing. Methods: Using a miCAR gene construct, we developed anti-CD19 CAR T-cells with multiplex silencing of six cell surface receptors, namely the T-cell receptor (TCR), human leukocyte antigen class I (HLA-I), CD52, PD1, TIM3 and TIGIT. Primary T-cells were modified via lentiviral vector transduction, expanded in G-Rex cell culture plates, and purified by depletion of TCR-expressing cells. Characterization of miCAR T-cells included flow cytometric immunophenotyping, functional activity against CD19-expressing tumor cells, and mixed lymphocyte reactions (MLRs) to demonstrate loss of alloreactivity and protection against allogeneic CD8 T-cells and NK cells. Results and Conclusions: We demonstrate robust and reliable production of CAR T-cells with >99% TCR negativity and efficient silencing of all targeted receptors, while maintaining a favorable immunophenotypic profile with 52-71% being of naïve memory phenotype (n=3 donors). Functionally, our multiplex engineered miCAR T-cells also maintained efficient and specific cytotoxicity of CD19-expressing cells. Finally, we show negligible alloreactivity in one-way MLR assays when miCAR T-cells were co-cultured with unmatched donor cells (n=3); and with "tuned" silencing of HLA-I (70 ± 10%), protection against both CD8 T-cell and NK cell mediated depletion (n=3 unmatched donors). We therefore show efficient multiplex engineering of functionally active, non-alloreactive and hypoimmunogenic CAR T-cells with silencing of six target genes.

762 Modular Semi-Automated Clinical Scale Manufacturing of CAR-T Cells for Cancer Immunotherapy

Kunjan Desai, Ranganatha Somasagara, Namritha Ravinder

ThermoFisher Scientific, Carlsbad, CA

With recent increases in clinical trials chimeric antigen receptor (CAR)-modified T cells have gained lot of enthusiasm in the field of cancer immunotherapy. Rapid development in this field and the need for generating cost effective, efficient cell therapies with predictable manufacturing results has also increased the demand for continuous manufacturing improvement. The conventional CAR-T cell manufacturing workflows involve labor-intensive steps with complex sequence of manual and open processes, with minimal to no automation. Introduction of automated modular system can reduce human interventions in the CAR-T manufacturing workflow. In the methods described here, we used a closed automated counterflow centrifugation platform, to automate several cell processing steps within the CAR-T cell manufacturing process including PBMC isolation from frozen leukopak, electroporation (EP) buffer exchange and final wash and concentrate. To achieve successful CART generation, we used Xenon™ Electroporation system to deliver the gene editing payload into activated T cells. First, we isolated the PBMC from frozen leukopak by using Rotea™ system and activated T cells using CD3/CD28 CTS™ Dynabeads™. The activated cells post de-beading was resuspended in gene editing buffer and then electroporated to deliver the Cas9 RNP complex and anti CD19 CAR using Xenon™ electroporation system. Post electroporation cells were expanded over 11 days to reach 4 x10^9 cells. Post expansion and editing efficiency analysis, we observed upto 60 % anti CD19 CAR knock-in efficiency. The CAR-T cells were finally washed and concentrated by Rotea™ and analyzed for transgene expression and then cryopreserved for further functional studies. The functional cancer cell cytotoxic assay against the CD19 presenting Nalm-6 cells showed effective killing by anti CD19 CAR-T cells compared to control T cells with no transgene payload. Utilization of closed automated workflows described here helps reduce the labor-intensive open system hurdles and generates functional engineered CART cells.

763 Towards a Consensus Platform for Last-Mile Cell Therapy Handling, Preparation, and Administration

Nikhil S. Joshi, Marcus Foley, Malik Marlin

Cellular Vehicles Inc., San Mateo, CA

INTRODUCTION: Cell-based therapy is a novel treatment option in the toolkit of physicians. Given the success of CAR T cell therapies (CT), the field has exploded in interest and the FDA anticipates 5-10 new CT drug approvals per year over the next decade. Standards for cell collection and cell manufacturing have been established, yet standardized protocols for last-mile delivery of CTs (the process of handling, preparation, and therapy administration) in the clinic have yet to be established. Each FDA-approved CT product (e.g. Kymriah, Breyanzi, etc..) has a unique protocol. Hospitals are facing challenges with the overhead costs of CT; training and retaining of technicians, cell preparation, and post-infusion patient monitoring. With the upcoming deluge of CT drugs, there is a need for a better solution for delivering these therapies. Here we present a novel system developed to handle, prepare, and infuse CT products in an optimized manner. The system controls factors such as thaw rate, pressure, shear stress, wash, resuspension, and infusion, all to ensure cells are viable and functional once delivered into the body. Early data on several system capabilities and their impact on cell health is described hereafter. **METHODS & RESULTS:** The system enables rapid and controlled dry thaw in a pre-clinical setting in both cryobags and syringes (using unique freezable syringes developed for use with the system), matching ideal thaw rates recommended in literature. The system allows complex non-linear thawing, which has been shown to improve post-thaw cell health. The auto wash/resuspension capability has achieved levels of cell recovery on par with standard centrifugation based manual technique. The system can also filter and remove dead cells and debris, just prior to infusion. Given that cell debris is known to cause systemic toxicity in patients, this feature can reduce the severity of post-infusion toxicity. Finally, the controlled infusion capability significantly improves cell viability and functionality, in multiple cell types. The system and complementary disposable device can limit peak pressure, pressure fluctuations, shear stress, and cell-material interactions. The link between cell viability, functionality and therapeutic efficacy is well established in literature, with research demonstrating just 10-15% viability loss can completely negate the efficacy of a CT.

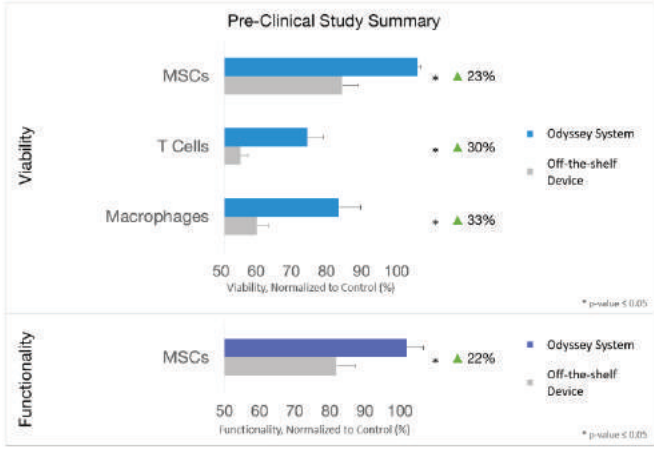


Figure: Results of pre-clinical studies using several cell types, including human MSCs, T Cells and macrophages. Cell viability was measured via an alamar blue assay, and functionality was measured via an ELISA assay of MSC IL-6 expression. n=3 per bar, * indicates $p<0.05$.

CONCLUSION: The handling, preparation, and final administration of CT products has largely been overlooked as an area for innovation and cost-reduction. The inconsistencies during patient-side CT delivery today include uncontrolled agitation causing cell death, breakage of the temperature preservation chain causing cells to senesce or apoptose, exposure to centrifugation or other separation techniques during washing and resuspension, and high pressure and shear stress during manual infusion. Cell-based medicines require strict control over their entire chain of custody. Here we describe a novel platform which enables standardization and improvement of last-mile CT delivery, a vital step for future clinical success.

764 Riboswitch-Regulated Chimeric Antigen Receptor, RiboCAR Enhances T Cell Activity

Xuecui Guo, George Wang, Zhaojing Zhong, Zhikai Zhang, Samuel Waksal, Alexandria Forbes
MeiraGTx, New York, NY

Chimeric antigen receptor (CAR)-T cell therapy is a promising therapy against cancer. However, the level of CAR molecule is important for CAR-T cell activation and their anti-tumor activities. Here, we present the development of RiboCAR, a mammalian synthetic riboswitch-based gene regulation system for regulating CAR expression level via small molecule inducer. Unlike previously reported regulatable CAR platforms that utilize viral protease or chemical-induced protein dimerization, RiboCAR contains an ON riboswitch in the coding sequence of a CAR transgene, in which the aptamer functions as a sensor for a specific novel small molecule inducer. The expression level of the CAR gene with the riboswitch completely depends on the presence of the riboswitch inducer, with undetectable CAR in the absence of the small molecule and a dose response in CAR level reaching levels higher than constitutively active CAR upon maximal small molecule induction. The induced CAR expression diminished after withdrawal of the small molecule inducer. Further, CAR expression is titratable in response to the levels of the small molecule inducer. Consistent with small molecule induced expression of the CAR molecule, CAR triggered-activation of CAR-T cells is also controlled by the small molecule inducer. More importantly, T cells with RiboCAR showed enhanced target cell-stimulated T cell activation when compared with T cells constitutively expressing CAR. With a bioavailable small molecule inducer, CAR-T activity can be precisely tuned and "remotely" controlled *in vivo*, both temporally and spatially, thus improving the efficacy and providing a safety mechanism for CAR-T cell therapy.

765 Scalable Continuous-Flow Electroporation Platform That Enables Primary Immune Cell Engineering for Cellular Therapy Manufacturing

Jacob A. VanderBurgh, Thomas Corso, Stephen Levy, Harold Craighead
CyteQuest, Ithaca, NY

Cellular therapies using autologous T cells expressing chimeric antigen receptors (CARs) have generated enthusiasm for their rates of remission but largely rely upon viral vectors for cellular reprogramming which are currently limited by expensive manufacturing, immunogenicity, and incompatibility with CRISPR/Cas9 gene editing. Electroporation has emerged as an alternative but widespread adoption requires addressing traditional electroporation difficulties including 1) variability, 2) arduous empirical optimization, and 3) limited throughput. In the present study, we describe a novel electroporation platform capable of rapid and reproducible electroporation that can seamlessly scale delivery from the research to the clinical scale. Our device consists of a continuous-flow, planar microfluidic channel (Figure 1A-B). Our design 1) ensures cells experience reproducible electric fields, 2) enables rapid sweeping of transfection parameters through robotic automation, and 3) seamlessly scales experimental throughput by scaling the channel width. As a demonstration of our system's capabilities, Jurkat or primary T cells from healthy donors were electroporated within CyteQuest's proprietary microfluidic flow chips. Jurkat cells were transfected with green fluorescent protein (GFP) encoded by plasmid DNA or mRNA. T cells were transfected four days after activation with CD3/CD28 antibodies with CRISPR/Cas9 ribonucleoprotein (RNP) complexes targeted against T cell receptor (TCR). GFP expression was measured via flow cytometry 24-h post-transfection. CRISPR/Cas9-mediated knockdown of protein expression was evaluated at 72-h post-transfection using anti-human TCR-α antibody and flow cytometry. Viability was measured during flow analysis using 7-AAD viability dye. To demonstrate seamless scaling, we transfected Jurkat cells with mRNA encoding GFP in either a 2- or 10-mm channel. Proportionally increasing the flow channel width (2 mm to 10 mm) with the volumetric flow rate results in identical mechanical, electrical, and chemical environments experienced by the cells. We observed roughly identical (less than 1% different) GFP expression and viability values in the 2- and 10-mm channel widths, demonstrating our ability to seamlessly scale (Figure 1C). To further demonstrate our scaling abilities, we transfected Jurkat cells with plasmid DNA encoding GFP in a 20-mm channel at a rate of 500 million cells/minute. Notably, we observed high GFP expression (86 ± 1.2%) with high viability (89 ± 1.4%) (Figure 1D). Finally, we delivered clinically significant cargo to primary T cells, using CRISPR/Cas9 RNPs to knock-down TCR expression. TCR expression was reduced from 89% ± 1% in control cells to 12% ± 2%, representing an ~88% knockdown (Figure 1E). These results demonstrate the capabilities of CyteQuest's novel electroporation platform for high efficiency and high viability delivery of multiple cargo to Jurkat and primary T cells. The innovations afforded by our microfluidic platform and its superior performance make it a promising system for non-viral cellular reprogramming for cell therapies.

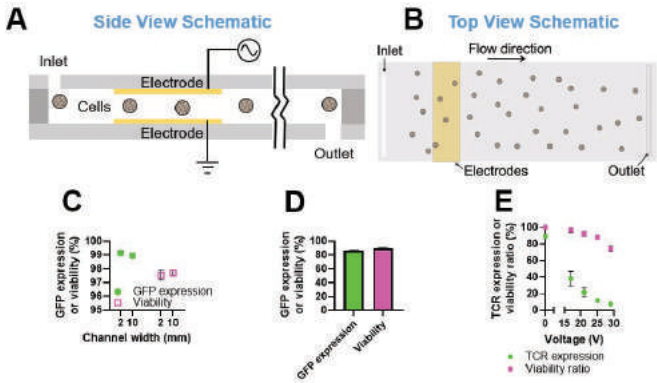

Figure 1: (A) Side and (B) Top view schematics of microfluidic flow chip. (C) GFP expression and viability data from Jurkat cells transfected with mRNA encoding GFP in either a 2- or 10-mm wide channel. (D) GFP expression and viability data from Jurkat cells transfected with plasmid DNA encoding GFP in a 20-mm wide channel. (E) TCR-α expression or viability data from T cells transfected with CRISPR/Cas9 RNPs.

766 Physiologix™ Serum-Replacement and NB ROC™ T Cell Culture Media Combination Shows Enhanced T-Cell Transduction Efficiency for CAR-T Therapy

Asma Ayari, Nanami Kadota, Brad Taylor
Nucleus Biologics, San Diego, CA

CD19 Chimeric Antigen Receptor (CAR-T) T cell therapy has shown a great potential for the treatment of B-cell malignancies and lymphoma and an increased number of studies are in progress for its translation to solid tumors. Success of this treatment is unfortunately limited by multiple factors such as donor-to-donor variability, patients response to the therapy and, manufacturing related issues. After leukapheresis, isolated T cells are manipulated under artificial conditions to be transfused back to the patient. Since these steps are conducted outside of the cell's natural surroundings, maintaining cell viability and their ability to proliferate without exhaustion and improving transduction efficiency are pillars for the success of the therapy. Thus, using the appropriate reagents is crucial for the treatment to be efficient, which will subsequently affect the quality of the end product and potentially increase the number of treated patients. Cell culture media is a critical factor to consider when improving the process as it is intimately linked to cell function and metabolism. In this study we tested a new cell culture media, NB-ROC™, developed specifically to support activated T cell proliferation and lentivirus transduction. Based on our previous data generated with the University of Pennsylvania on T cells, we supplemented NB ROC™ with 2% Physiologix™ XF (Human Growth Factor Concentrate (hGFC) , a cGMP, xeno-free media supplement made for stem cells and T cells). Compared to CTS™ OpTmizer™ T-Cell Expansion supplemented with 5% human serum, NB ROC™ shows on a Dynabeads-activated T cell model, a maintained proliferation rate and population doubling with a preserved phenotype, determined through the evaluation of surface expression markers such as PD-1, CCR-7 and CD45-RO over a period of 7 days. Lentivirus transduction data is more compelling as it shows an increased level by 20-30% compared to OpTmizer supplemented with human serum. Our data also confirms previous observations on Physiologix, as supplementing CTS™ OpTmizer™ with 2% Physiologix™ shows also significant transduction efficiency improvement compared to when it is supplemented with 5% human serum. All in all, our data show that NB ROC™; as serum free media combined with Physiologix™ ; offers a very promising alternative for an improved T cell transduction efficiency with a maintained phenotype and proliferation rate on both 6 well plate and G-Rex model. This set of data holds the promise for enhancing transduction efficiency for CAR-T therapy which will help ameliorate the process and bring more success to the field.

767 Development of an In-House Suspension Lentiviral Vector Production Cell Line to Accelerate Manufacture of Cell Therapy Products

Joshua Gutierrez
Theragent Inc., Arcadia, CA

Lentiviral vectors offer excellent gene delivery vehicles for cell and gene therapy applications. Traditionally, adherent HEK293 T cells are transiently transfected with second or third generation vectors to generate lentiviral (LV) particles. Although this approach serves the need for preclinical research labs, adherent cells pose inherent difficulties when scaling up to produce GMP grade vectors. While production can be scaled up with adherent HEK293T using multi-stack cell culture flasks, it is not cost effective and operationally inefficient. Furthermore, dependency of FBS for growth poses additional disadvantage and safety risk for clinical products. To facilitate large scale production of GMP grade LV we adapted adherent HEK293T cells (ATCC, from SACF) to suspension culture using Thermofisher's serum free lentiviral production medium. The adapted 293 T suspension cells (293TS) produced lentiviral titers comparable or superior to Thermofisher's lentiviral production cells under different conditions. To build a self-sufficient inexpensive production platform, we optimized production conditions that eliminates the requirement of commercial transfection reagents or packaging cocktails. We validated this cell line for production of LV encoding chimeric antigen receptors (CAR). Currently, we offer high titer RUO grade LV production service using this cell line. Further optimization and scaling up is in progress.

768 Quantification of Single Cell Vector Copy Number in CAR T Cell Products Utilizing a Novel Microfluidic Technology

Khushali Patel
R&D, Mission Bio Inc., South San Francisco, CA

Cell and gene therapies are altering the treatment landscape of intractable genetic disorders, including cancer and inherited diseases. One of the transformative solutions to treat cancer patients has been the Chimeric antigen receptor T-Cell (CAR-T) immunotherapy. As most CAR-T therapies rely on the modification of host cells with CAR using lentiviral vectors, followed by the re-introduction of the modified T-cell into the patient, the quality of these modified cells is extensively regulated to warrant safety. Accurate measurement of gene transfer as well as viral vector copy number (VCN) is critical to therapeutic development and a key attribute for assessing safety and efficacy. Conventional methods measuring VCN report out population average (bulk) or involve laborious and time-consuming single-cell clonal outgrowth procedures which could take up to months to complete. Here, we introduce a novel microfluidic workflow to precisely measure vector copy number as well as transduction efficiency across thousands of cells at a single-cell resolution in a shorter time frame. The technology is enabled by a two-droplet system. The first droplet encapsulates thousands of cells individually followed by lysis of the cells, releasing DNA from its heterochromatin state for uniform DNA interrogation. The second droplet generation involves uniquely barcoding individual lysates and amplifying the target DNA via multiplexed PCR inside each droplet. The targets are processed using NGS library preparation methods and the final products are sequenced on an NGS sequencing instrument. In this study, the single-cell VCN data generated using our vector-specific targeted assays was orthogonally validated by ddPCR single assays to obtain a correlation of 99% (Fig.1). Using vector-specific amplicons to classify cells as transduced or non-transduced allows us to calculate the percent transduction for each sample. Using admixtures of transduced and non-transduced cell lines, we show our % Transduction assay has >98.8% and >99.2% specificity and sensitivity.

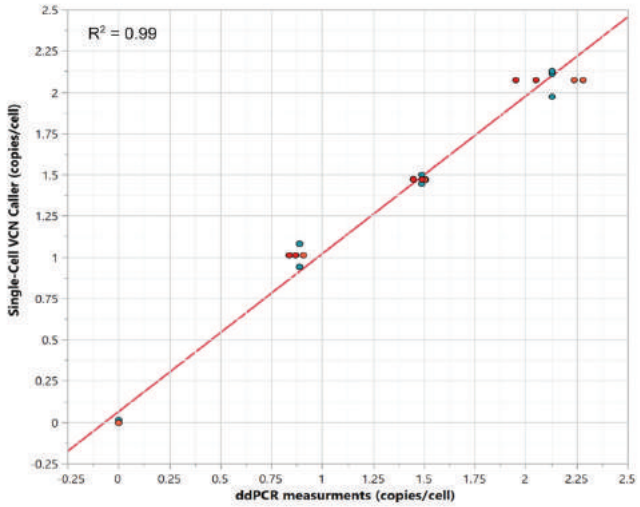

Fig.1: Additionally, using our single-cell DNA+Protein capabilities, we were able to genotype clonal Jurkat cells (VCN=2) and donor PBMCs based on the detection of SNV, and CNV, and phenotypically profile them based on surface protein marker expression (Fig.2)..

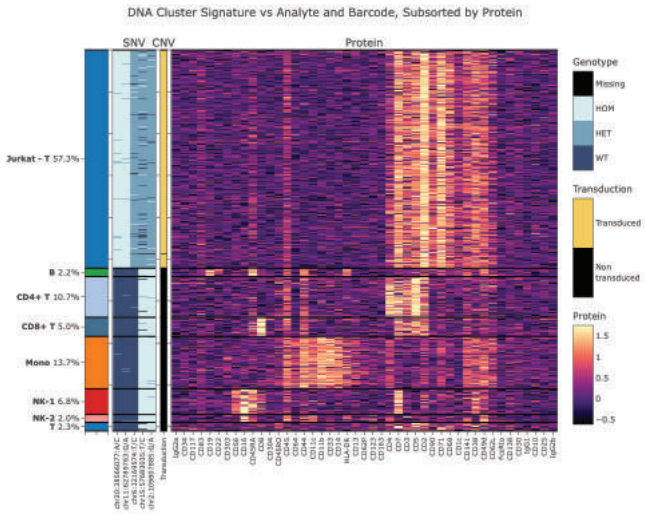

Fig 2: Future studies will evaluate the utility of this technology in measuring both CAR transgene copies and surface expression/ density of the CAR at the single cell level, improving the potential of our technology to provide more precise measurements of CAR T cell therapeutic product attributes before releasing the treatment to patients.

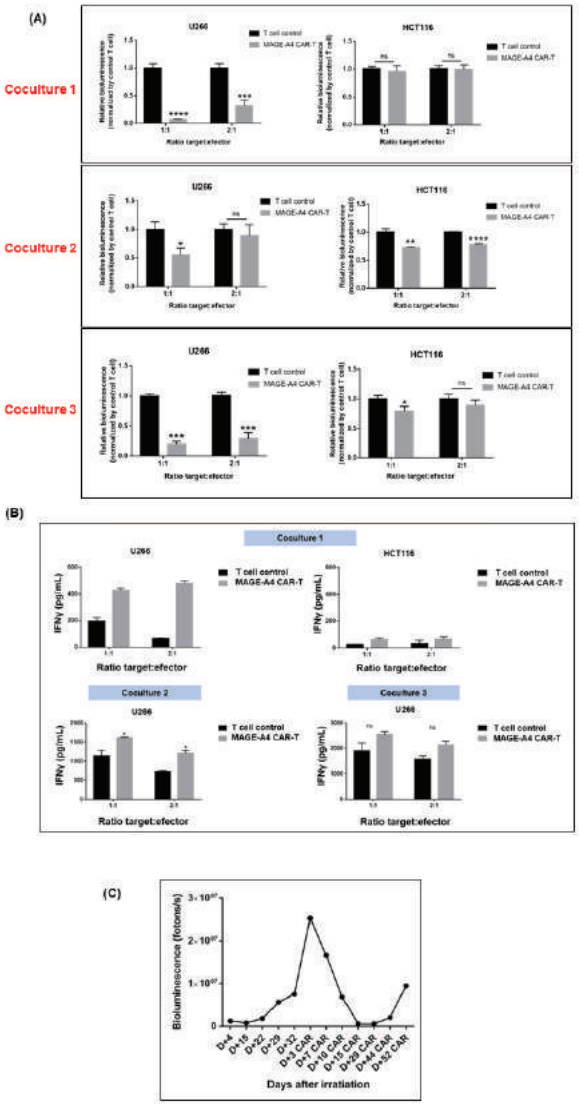
769 A New CAR Against the Intracellular Target MAGE-A4 is Capable of Lysing Multiple Myeloma Cells *In Vitro* and *In Vivo*

Roberta Maraninchi Silveira[1], Izadora Furtado[1], Rafaela Rossetti[1], Daianne Fantacini[2], Andreza Urba[2], Sarah Lima[1], Lev Tsyrenov[3], Hiroshi Shiku[4], Dimas Covas[1], Lucas Souza[1]

[1]Ribeirao Preto School of Medicine University/ University of São Paulo, Ribeirão Preto, Brazil,[2]Biotechnology Nucleus of Ribeirao Preto / University of Sao Paulo, Ribeirão Preto, Brazil,[3]Mie University, Tsu, Japan,[4]Mie University, Tsu, Mie, Japan

Background: Conventional chimeric antigen receptors (CARs) can recognize only cell-surface antigens in their native conformation. This greatly limits the number of suitable targets since most tumor-associated antigens are intracellular. The T cell receptors (TCR) expressed naturally in T cell usually have low binding affinity, and studies demonstrated that artificially increasing of TCR affinity might lead to unwanted binding to self-antigens. **Aims:** In this work, we report the development of CAR-T cells expressing a novel CAR capable of recognizing the intracellular tumor-associated antigen MAGE-A4 presented by HLA-A*02 molecules, which is the most frequent serotype in the western world. MAGE-A4 is a cancer-testis antigen expressed by a wide myriad of neoplasms, including late-stage multiple myeloma (MM). **Methods:** We generated a novel lentiviral vector coding a CAR harboring a recognition domain derived from an antibody specific to a MAGE-A4:HLA-A*02 complex. Next, we produced lentiviral particles and used them to transduce primary T cells. The resulting MAGE-A4/ CAR-T cells were cocultured with luciferase-expressing U266 MM cells (MAGE-A4$^+$) or HCT116 colon carcinoma cells (MAGE-A4$^-$) to assess their antineoplastic potential *in vitro*. We also evaluated IFNγ release during coculture and tested the antitumor potential in a MM xenograft model using NSG mice. **Results:** Transduction efficiencies of new MAGE-A4 CAR vector were high, reaching 57% to 84% in two transductions of different donor samples. These transduced cells displayed normal growth *in vitro* and stable expression of the CAR after 14 days of expansion. The percentage of in vitro tumor cell lysis using CAR-T cells derived from three different donors were 50%, 93% and 45%, respectively. Accordingly, CAR-T cells secreted IFNγ during coculture with U266^{luc} cells, but not with HCT116^{luc} cells, confirming the target-specificity. In an aggressive MM xenograft model, we observed that the MAGE-A4/CAR-T cells induced a strong tumor regression in established high-burden MM grafts, followed by relapse of the diseases after two weeks. **Conclusions:** We demonstrated the generation of a novel lentiviral vector coding a fully functional CAR which was able to redirect the cytotoxic activity of T cells against MAGE-A4+HLA-A*02$^+$ MM cells in vitro and in vivo. These results lay the groundwork for the establishment of a novel advanced cell therapy against MM and other MAGE-A4$^+$ malignancies.



770 Harnessing the Power of Multiomics from a Single Sample with Advanced Automation for Sample Handling and Processing

Andrea O'Hara[1], Laure Turner[2], Haythem Latif[1], Chris Mozdzierz[1], Ginger Zhou[3]

[1]Azenta Life Sciences, Burlington, MA,[2]Genewiz From Azenta Life Sciences, South Plainfield, NJ,[3]Genewiz, Inc./Brooks, South Plainfield, NJ

The omics era has greatly expanded the repertoire of approaches available for researchers and clinicians to unravel the complexity underpinning human health: Next Generation Sequencing (NGS) approaches can characterize genomes, epigenomes, transcriptomes and proteomes. The analyses are critical to assess in individuals both pre- and post-treatment during therapeutic development and early-stage clinical trials. Peripheral blood mononuclear cells (PBMCs) offer a window into the immune system that, when combined with these omics tools, can provide a near holistic view of immune processes across patient cohorts. Here we detail a workflow using a single blood draw to rapidly produce a diverse set of multiomics results including genomics, epigenomics, transcriptomics and proteomics. This starts with automated sample handling and processing of the primary blood draw to ensure high viability and yield of PBMCs, along with simultaneous plasma separation and collection. These samples are then aliquoted and simultaneously processed for automated and semi-automated whole exome sequencing, single cell RNA sequencing, epigenetic characterization and Olink proteomic assays. With this robust workflow and advanced robotics for sample handling and processing to minimize potential batch effects, all these datatypes can be produced within days of primary sample collection using minimal sample amounts. High throughput integrative omics workflows, as described here, drive greater insights in human health, allowing for a rapid combined approach to address the biological questions at hand.

771 Validation of a Powerful Analytical Method - ECLIA-Based Assay - for Total AAV Particles Quantification

Frederic Broucque, Maël Khoja, Sylvie Saleun, Oumeya Adjali, Véronique Blouin, Héloïse Fonteneau

TaRGet - Translational Research in Gene Therapy, Nantes, France

The analytical quantification of recombinant adeno-associated viral (rAAV) particles is an important part of the Quality Control panel for rAAV-based gene therapies. Correlated to viral genome quantification, the viral particles quantification allows the definition of empty/full particle ratio. This ratio is a critical quality attribute, as a high ratio can impact the therapeutic effect and increase rAAV immunogenicity. Viral particle quantification is performed both on in-process samples to define the critical process parameters leading to a better yield; and on the drug product to fulfill quality requirements. ELISA (enzyme-linked immunosorbent assay) is currently the gold-standard method for total AAV particle quantification within analytical departments. We recently developed an alternative ECLIA-based assay (ElectroChemiLuminescence Immunosorbent Assay) associated to the Meso QuickPlex SQ 120® plate reader. This alternative method shows a wider dynamic range than the reference method (4,5 log vs 2 log for the reference method). This larger range is a real asset to characterize both in-process and final drug product. Expanding the quantification range also reduces the number of retests in case of out of range sample (cost- and time-saving, improvement of sample comparability within the same run). Furthermore, this ECLIA-based assay presents a lower cost than the reference method (75% saved). Reducing the quality control cost is part of the current challenges in gene therapy, in order to reduce global manufacturing cost and improve accessibility of these therapies to patients. To better integrate the industrialization rAAV work flow, this ECLIA-based assay was validated, as required by the good manufacturing practices (GMP), for the quantification of total rAAV8 viral particles using the EMEA and FDA guidelines for bioanalytical method validation. The validation showed a broad quantification range, from 1,25E7 particles/mL to 2,50E11 particles/mL. The specificity and selectivity performances demonstrated the absence of interference from standard culture media of HEK293 (human embryonic kidney 293) and Sf9 (clonal isolate of Insect Spodoptera frugiperda Sf2) cells, as well as the absence of cross-reactivity with rAAV serotype 2. The between-run and within-run precisions showed a coefficient of variation below 20% and 36%, respectively. Finally, the accuracy performances (below

2-fold from target concentration) were comparable to those historically obtained between-run with the reference method and were aligned with internal validation performances for viral genome and residual DNA quantification by qPCR. In conclusion, this alternative ECLIA-based assay was successfully validated for routine use within the production workflow of our AAV vector core and could be included in a global tech transfer to a GMP environment.

772 Method Qualification of Mass Photometry for the Determination of Full-to-Empty Capsid Ratio for rAAVs Using the Refeyn System

Christine Zach, Sebastian Ritter, Tobias Klötzler, Alexandra Schoberth, Sonya M. Schermann
Ascend GCTx, Martinsried, Germany

Packaging heterogeneity in recombinant adeno-associated virus (rAAV) manufacturing leads to potential product-related impurities including 'empty' capsids, capsids containing partial vector genomes, and capsids containing host cell or plasmid-derived DNA impurities. Methods for calculating full-to-empty ratios often place capsids into two broad categories: capsids containing DNA of approximately the size of the full-length vector ('full') and capsids which contain little to no DNA ('empty'). The ability to characterize capsids that contain shorter DNA fragments or fragments that are substantially longer than the full-length vector depends on the method used and the length of the vector genome. The full-to-empty ratio of rAAV capsids is considered a critical quality attribute because it may affect both safety and efficacy. The total capsid load of both 'full' and 'empty' capsids may contribute to immunogenicity and acute toxicity, which has been observed in clinical trials with high doses. On the other hand, there is evidence that empty capsids can reduce clearance by acting as decoys, resulting in increased potency *in vivo*. Therefore, the full-to-empty ratio should be carefully considered during development. Manufacturing processes should deliver consistent full-to-empty ratios, and methods to monitor this attribute are required for release of drug product. Analytical ultracentrifugation is the current gold standard method for determination of full-to-empty ratio. Although this method provides accurate and precise results, significant sample volume is required, and analysis must be carried out by highly skilled operators. Alternative methods, such as cryogenic electron microscopy (CryoEM) require less volume, but also need expensive specialist equipment and skilled operators. Recently, mass photometry has emerged as an alternative method for the determination of the full-to-empty ratio. This method provides results in minutes with microliters of sample using a benchtop instrument (Refeyn) and requires only basic operator training. To demonstrate that the method is fit-for-purpose in monitoring the full-to-empty ratio of rAAV samples, we performed method qualification according to the principles of ICH Q2(R1) using rAAV samples in matrices and buffers commonly used in the production processes. Here we present data that support future validation of the method for use as a release assay in a regulated environment.

773 Utilizing AAV Entry Factors & Small Molecules to Synergistically Enhance Vector Transduction and Transgene Expression to Facilitate the Development of *In Vitro* Cell-Based Assays for AAV Gene Therapy

Kayla M. Shumate, Blanca Lopez de Juan Abad, Liang Zhou, Xiaodong S. Fang
Translational Medicine, Asklepios BioPharmaceutical, Durham, NC

A common impediment to the development of *in vitro* cell-based assays for Adeno - associated virus (AAV) gene therapies (such as potency and AAV NAb assays) is poor transduction and transgene expression, which prevails across cell lines and AAV serotypes. Recently, several proposed AAV entry factors have been identified, whose overexpression could enhance AAV transduction efficiency. In this study, we tested a panel of proposed AAV entry factors in HepG2 cells by transient overexpression combined with AAV8 transduction. Overexpression of the AAV receptor (*AAVR*) prior to AAV8 transduction resulted in a 19-fold enhancement of transduction, whereas G-protein coupled receptor 108 (*GPR108*) expression increased transduction by 2-fold, and laminin receptor 1 (*LAMR1*) and transmembrane 9 superfamily member 2 (*TM9SF2*) expression had no effect compared to control. *AAVR* overexpression was further tested in an alternate cell line, HEK293, with a different serotype, AAV2i8, and a similar enhancement of transduction efficiency was observed. Next, a panel of small molecules were screened in HepG2 cells for their ability to enhance transgene expression. Twenty-four hour treatment with 10 μM of the topoisomerase II inhibitors, etoposide and teniposide, improved transduction efficiency 3-fold and 2.4 μM of the ER-associated protein degradation (ERAD) inhibitor, Eeyarestatin 1, improved transduction 4-fold compared to non-treated. Finally, the small molecules and AAVR entry factors were evaluated in combination for a synergistic effect. Overexpression of *AAVR* and 10uM etoposide treatment resulted in a 31-fold enhancement of transduction over control, confirming the synergistic effect between *AAVR* and small molecule treatments, suggesting that they impact different steps of the AAV transduction and transgene protein expression process. We believe the approach could be broadly applied to a range of cell lines and AAV serotypes to enable more rapid development of *in vitro* cell-based assays for AAV gene therapeutics.

774 Measuring RAAV Genomic Titer, Viral Particle Titer and Full/Empty Capsid Ratio on the Applied BioSystemsTM QuantStudioTM Absolute QTM dPCR System

Kimberly Lim
Thermo Fisher Scientific, South San Francisco, CA

Recombinant adeno-associated viruses (rAAV) are widely used for human gene and cell therapies due to their low immunogenicity, vast tropism and efficient and persistent gene transfer properties. However, effective potential dosing requires the use of well-characterized and optimized concentrations of viral vectors. Accurate and consistent viral titer measurements are needed throughout all phases of rAAV vector production from early stages of developing AAV expression systems to production scale-up and

final product release to ensure precise and appropriate dosing. Quantification of genomic titer (GC/mL) and viral particle titer (vp/mL) as well as the ratio of full to empty capsids are important rAAV attributes. However, quantification is not done in a harmonized manner. Other limited methods can measure single rAAV characteristics: qPCR measures genomic titer while viral particle titer is measured by ELISA. Full/empty ratio can be inferred from the combination of qPCR and ELISA data or measured independently by electron microscopy, analytical ultracentrifugation, or high-pressure liquid chromatography. We have demonstrated the feasibility of measuring genomic titer, particle titer and the full/empty ratio using a combination of proximity ligation assay (PLA) technology and Taqman assays on a qPCR platform. However, this approach requires the use of standard curves for determining particle and genome titers. As such, the method is more susceptible to inter-assay variation. Here, our proof-of-concept experiments demonstrate that genome titer, viral particle titer and full/empty capsid ratio can be measured on the Absolute Q platform using PLA and Taqman assay workflows (Figure 1). Digital PCR offers a simplistic approach to measuring nucleic and protein concentrations without the need for a standard curve. For two AAV serotypes tested, the full/empty capsid ratio obtained from dPCR aligned closely with the same measurement derived from qPCR standard curves. We also observed that the estimated viral particle and genomic titers were higher in qPCR compared to dPCR; this over-estimation by qPCR titers may be due to the reliance on a standard curve generated from a reference sample of the same serotype(s). In summary, we demonstrate the initial feasibility of determining AAV genome titer, viral particle titer and full/empty capsid ratio in a single duplexed dPCR. In this work, we used commercially available purified AAV particles as the test samples. Further work is needed to understand the impact of using unpurified or partially purified samples on duplex assay performance. Similarly, the impact of different purification methods on performance must be investigated. Overall, this idea overcomes several important challenges in AAV characterization: 1) the need for separate analytical platforms for genome and particle titer measures, 2) the need for standard curves for quantification, and 3) the need for fast and consistent results.

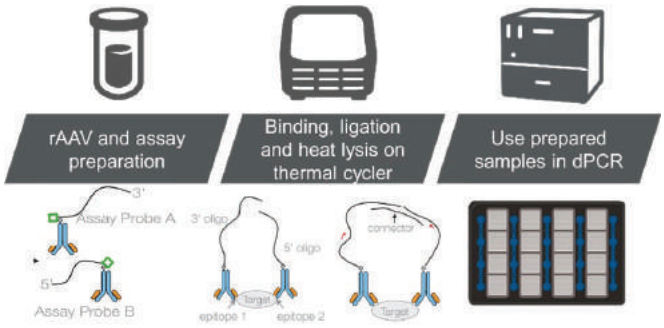


Figure 1. AAV-PLA workflow

775 A New Two-Dimensional Droplet Digital PCR Method for AAV Intact Viral Genome Titer Analysis

Tam Duong, Peng Wang, Jacob Mardick, Bingnan Gu
Lonza Houston Inc., Houston, TX

Recombinant adeno-associated virus (rAAV) has been a vector of choice for *in vivo* gene delivery with many clinical trials for the treatment of human diseases. The clinical use of rAAV in gene therapy requires a precise quantification method for viral vector products. The current single channel ddPCR method provides incomplete pictures regarding rAAV genome integrity, i.e. complete vs. partial genome. In this study, we applied multiplexing 2D ddPCR to thoroughly characterize a rAAV product by providing new information on intact viral genome titer. Particularly, we designed the amplicon sites targeting both ends of the viral genome to ensure capturing the full-length viral genome in the analysis. We showed that the selections of appropriate PCR amplification sites are critical to precisely evaluate the viral genome integrity. Together with the application of linkage analysis using QuantaSoft software, we can accurately calculate the intact viral genome titer and the percentage of full-length rAAV among all genome-containing species in the product. Therefore, this new method can serve as quick characterization and titer assays for both process development and final product release with improved robustness, accuracy and precision.

776 Allometric-Like Scaling of AAV Gene Therapy for Systemic Protein Delivery

Raphaela Bento[1], Alexandra Burr[1], Patrick Erickson[2], Kariman Shama[1], Charles M. Roth[2], Biju Parekkadan[1]
[1]Biomedical Engineering, Rutgers University, Piscataway, NJ,[2]Chemical and Biochemical Engineering, Rutgers University, Piscataway, NJ

Introduction: The use of adeno-associated virus (AAV) as a gene delivery vehicle for secreted peptide therapeutics can enable a new approach to durably manage chronic protein insufficiencies in patients. Yet, dosing of AAVs has been largely empirical to date. In this study, we explored the dose-response relationship of AAVs encoding a secreted Gaussia luciferase (GLuc) reporter or a bioactive candidate (parathyroid hormone; PTH) to establish a mathematical model that can be used to predict *in vivo* steady-state protein concentrations in mice based on steady-state secretion rates *in vitro*. **Methods:** A pharmacokinetic study was performed following intravenous administration of AAV2-EF1a-GLuc at two doses ($2.5x10^9$ and $1x10^{10}$ vg) in mice. GLuc concentration was measured in the plasma for up to 8 weeks post-injection. Tissue-specific vg content was measured by qPCR to identify target tissues. *In vitro* secretion assays were performed by transducing HepG2 cells with AAV doses ranging from 10^3 to 10^7 vg. A continuous perfusion bioreactor culture system was used to measure GLuc secretion rate *in vitro* as a model for tissue release in the bloodstream. Dose-response data were plotted for both systems and fit to a E_{max} model using GraphPad Prism. AAV2-EF1a-PTH vectors were injected in mice at two doses: $10^{10.8}$ or $10^{11.3}$ vg. For model validation studies, PTH steady-state concentration was measured in the plasma at weeks 3 and 5 post-injection. **Results:** The level of secreted luciferase reporter *in vivo* reached a steady-state concentration (C_{pss}) 3 weeks post AAV injections (Fig.

1A). The concentration of vg in liver tissues was over 10 times higher than other tissues, being considered the primary organ of protein production (Fig. 1B). The dose-response curves were well-fit by a E_{max} model, with a maximum steady-state secretion rate (R_{ss}) of 46.35ng/h (Fig. 1C). An *in vitro* dose-response curve was then derived as a model for liver parenchymal cell transduction, using the same AAV2 vector. A similar hyperbolic relationship was found between viral dose and R_{ss} *in vitro* (Fig. 1D). Parameter values for both systems were compared and a scaling equation was generated (Fig. 1E). The predictivity of our scaling model was confirmed using an AAV2 vector encoding a therapeutic protein. Predicted concentrations of PTH were calculated as a function of dose, considering PTH-specific parameters. Predicted values were very close to actual data from animals receiving two different doses of the vector (sensitivity: ± 4 pg/mL) (Fig. 1F). These results support the applicability of these scaling factors for other secreted transgenes delivered by AAV2. **Conclusions:** These studies provide a framework for scaling of *in vitro* studies of AAV-driven secreted proteins to target specific *in vivo*blood concentrations. Our model confirmed that plasma steady-state concentrations of secreted proteins expressed by AAVs can be guided by *in vitro* kinetic secretion data laying groundwork for future customization and model-informed dose justification for AAV candidates.

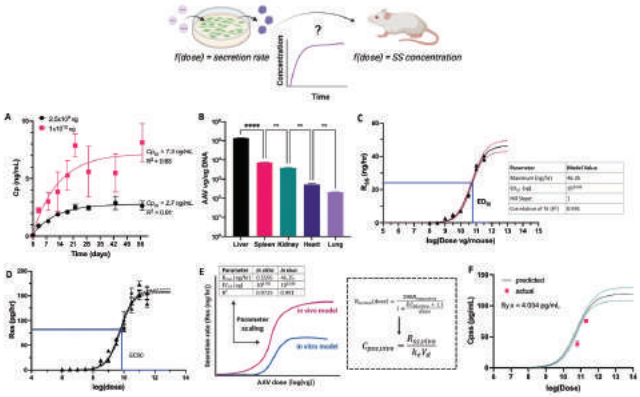

Figure 1. Developing a model for predictive dosing of gene therapeutics expressing secreted proteins. (A) Plasma concentrations of GLuc over time following AAV injection. (B) Viral genome in various tissues. (C) Dose response of steady-state rate *in vivo* with extracted model parameters. (D) Calculated *in vitro* secretion rate as a function of viral dose. (E) Parameters from both systems can be used to derive a scaling relationship. (F) Equation from model derivation can be used to predict concentration of PTH as a function of dose *in vivo*. Pink data points show actual concentrations.

777 Single Molecule, Real-Time Sequencing of Replication-Competent Adeno-Associated Viruses in Gene Therapy Vector Preparations

Mitchell Yip[1], Jing Chen[2], Yan Zhi[2], Ngoc Tam L. Tran[1], Suk Namkung[1], Eric Pastor[2], Guangping Gao[1,3], Phillip WL Tai[1,3]

[1]UMass Chan Medical School, Worcester, MA,[2]Spirovant Sciences, Inc, Philadelphia, PA,[3]Co-corresponding Authors, Worcester, MA

Adeno-associated virus (AAV) vectors continue to be the leading platform for gene therapy because of their low relative immunogenicity, broad tissue tropism, and ability to deliver a diversity of therapeutic gene products. Unfortunately, AAV manufacturing faces several challenges with contaminants, drawing increased attention and concern. Following production, AAV preparations undergo a series of diagnostic tests to assess titer, purity, and the presence of DNA contaminants. These DNA contaminants most commonly originate from components used in the AAV production process and encompass plasmid DNA, non-unit length vector genomes, host-cell DNA, and adventitious virus genomes. One type of contaminant that remains poorly understood is replication competent (rc)AAVs. rcAAVs form through genetic recombination events that yield intact, replicative, and potentially infectious virus-like virions. They are detected by passaging clarified lysates from cells transduced by AAV vectors in the presence of helper virus, such as adenovirus. Cellular lysates from the last passage undergo qPCR analyses to quantify rep-containing genomes. This methodology is effective in detecting rcAAVs, but it cannot determine the diversity of recombination forms, nor provide insights into how they originate. We have used AAV genome population sequencing (AAV-GPseq), a method that is based on single molecule, real-time (SMRT) sequencing, to detect and analyze rcAAVs from a test vector designed to treat respiratory disease. Our findings present evidence that sequence-independent recombination between the ITR-containing transgene cassette and the rep/cap plasmid can form from several events. This finding suggests that random recombination during production can form rcAAVs as long as all components for replication and packaging are present. Additionally, we have revised previously held requirements that permit rcAAV formation, which will aid in the development of novel AAV production strategies to further reduce rcAAV contaminants. Importantly, we have developed an advanced and robust method based on next-generation sequencing that can supplement standard quality control measures to ensure the safety of clinical vectors.

778 A Novel Solution Enabling Consistent Quantification of Viral Genome Titer without DNase Treatment

Subhanjan Mondal, Nathan Feirer, Trish Hoang, Morten Sierup

Promega Corporation, Fitchburg, WI

Adeno-associated viral (AAV) vectors show great promise as a delivery system for gene therapy. However, development of robust methods for quantitation, infectivity and dose-determination has remained a challenge. For quantification of viral genome titer, samples are typically pretreated with DNase to remove vector and packaging plasmid DNAs, and often time followed by proteinase K treatment to remove DNase and release DNase -resistant packaged viral genomes. The challenges using DNase include the incomplete digestion resulting in residual DNA outside the capsids and the inaccessibility of DNase to nucleic acid from partially ruptured viral capsids due to the large size of DNase. To address these challenges with DNase treatment, we developed TruTiter™, a DNase-independent method for quantification of viral genome. The TruTiter™ reagent is a small molecule consisting of a nucleic acid binding moiety, an alkylating group and the molecule is positively charged allowing exclusion from encapsulated biological entities. The crosslinking renders the nucleic acid non-amplifiable by PCR, allowing consistent quantification of viral genomes using dPCR or qPCR. The chemical design of the TruTiter™ reagent is modular in nature. Chemical screens were performed to select an intercalating group as a nucleic acid binding moiety, followed by optimization of alkylating group crosslinking warhead and the charge. After selection

of the lead compound, the concentration of use was determined for various AAV particles. The chemical was effectively excluded from AAV2, 8 and 9 at concentrations less than 100uM. 10uM concentration was used for all studies. The workflow involves addition of the TruTiter™ reagent to a sample for 30 minutes. This covalently crosslinks any nucleic acid that is free or from ruptured virus. Then a neutralization solution is added that stops the crosslinking process, followed by proteinase K treatment to release the protected DNA. The sample is then analyzed using qPCR or dPCR. We assessed the correlation of genome titers determined using the TruTiter™ procedure against the DNAse treatment method and compared the titer values to infectivity. We measured infectivity using a AAV2- NanoLuc® luciferase reporter assay. We generated a standard curve of viral concentrations. By comparing the luminescent value of cells treated with chemical or thermal challenged AAV to the luminescence of the standard curve the viral titer was extrapolated. Tm for AAV2 was 60°C for all the three assays. We then determined the variability in genome quantification measured using the Dnase and TruTiter™ methods. AAV2 were either incubated at 37°C or 65°C for 10 minutes and genome titers determined. For samples treated at 37°C both DNase and TruTiter™ indicated the same value with similar standard deviation. However, for samples treated at 65°C, the DNase treatment showed a two times higher average genome unit measurement and a 2.7 times greater standard deviation, indicative of TruTiter™ method being more robust for genome titer measurements. Next, we treated AAV2 samples with different cell lysis agents typically used in AAV manufacturing process, 0.1% Pluronic, 0.1% Tween and determined genome titers using both DNase and TruTiter™ methods. For both detergents genome tittering showed a greater standard deviation compared to the TruTiter™ method. This study demonstrates the inherent variability in viral genome quantitation when using DNase, and the variability is reduced when using a small-molecule based approach.

779 Early Detection of Tonic Signaling in Primary Human CAR-T Cells by Flow Cytometry

John Nguyen

Theragent Inc., Covina, CA

Chimeric Antigen Receptors (CARs) are intended to trigger T cell activation in response to binding to specific antigens. However, certain CAR designs and excessive levels of CAR expression have the tendency to constitutively activate T cells in the absence of ligands, which has been described as tonic signaling. This chronic spontaneous stimulation has been shown to accelerate T cell differentiation and exhaustion, ultimately leading to dysfunctional CAR-T cells with poor persistence and potency. Therefore, it is highly recommended to screen new CAR constructs for tonic signaling during pre-clinical development. Conventional methods to probe for tonic signaling include detection of CD3ζ phosphorylation in the absence of ligands (e.g. by Western Blot), as well as observation of abnormal T cell expansion kinetics and phenotypes which may manifest after extended culture. However, with the ongoing trend towards shorter processes for CAR-T cell production, earlier, simpler, and less ambiguous readouts are desirable. Here, we propose assessment of CAR ligand-independent surface expression of CD137 as an indicator of tonic signaling. On T cells, CD137 (also known as 4-1BB and TNFRSF9) is a co-stimulatory receptor of the tumor necrosis factor (TNF) receptor superfamily, and its expression strictly correlates with T cell receptor signaling. This property has previously been utilized to identify and isolate antigen-specifically activated T cells in various clinical settings, such as virus-specific T cells in ongoing infectious diseases, tumor-reactive T cells from tumor infiltrates, and alloreactive T cells in transplantation. We show by flow cytometry analysis that this expression pattern also applies to primary human CAR-T cells with tonic signaling through their CAR's CD3ζ endodomain. 72 hours after removal of polyclonal stimulants (e.g. anti-CD3 / anti-CD28 antibody-coated beads), CD137 surface expression remains elevated in T cells transduced with chronically activating CARs compared to untransduced T cells and CAR-T cells without tonic signaling, long before differences in other markers of T cell activation, exhaustion and differentiation (e.g. CD25, CD69, PD-1 and CCR7) become detectable. The kinetics and specificity of CD137 expression, coupled with the simplicity of including it in standard immunophenotyping panels for flow cytometry, make it a useful and attractive tool for pre-clinical characterization of CARs.

780 Development of a ddPCR Protocol for the Quantification of AAV Viral Genomes in Purified Samples

Nathalie Van Den Berghe, Tine Brouns, Els Henckaerts, Benjamien Moeyaert

Laboratory of Viral Cell Biology & Therapeutics, Department of Cellular and Molecular Medicine, KU Leuven, Leuven, Belgium

AAV (adeno-associated virus) is a non-pathogenic virus that is used as a delivery vehicle to transfer therapeutic genes into a patient's cells. Accurate quantification of AAV genome copies is essential for the optimization of the production and purification processes, preclinical studies, and clinical dosage of AAV-based gene therapy products. Several methods exist for the determination of the viral genome (vg) titer with quantitative PCR (qPCR) and droplet digital (dd)PCR being the two most widely used and accepted ones. ddPCR is preferred over qPCR because of the independence of the amplification efficacy, higher precision, and robustness. The aim of this study was to develop a ddPCR protocol for the quantification of AAV viral genomes in purified samples. Unpackaged contaminant DNA, amongst others DNA from the production plasmids and/or cell line, needs to be eliminated before viral genomes can accurately be quantified. We tested several protocols for their ability to remove unpackaged DNA while maintaining accurate packaged viral genome titers. To do so, we spiked plasmid DNA into purified AAV2 vector and evaluated the following sample treatment conditions: (A) incubation with DNAseI only; (B) DNAseI incubation followed by EDTA inactivation, 72°C heat inactivation, proteinase K treatment, and finally 95°C heat inactivation; (C) the same as condition B but with a final heat inactivation at 72°C instead of 95°C (D) no sample pretreatment. Plasmid and AAV genome copies were quantified through a duplex ddPCR (QX200 droplet digital PCR system, Bio-Rad). In contrast to condition D, where no sample treatment was performed, no plasmid DNA was detected in conditions A, B and C. A trend was observed towards lower AAV2 vg titers in condition B compared to conditions A and C (Figure 1). Interestingly, comparable vg titers were noted between conditions A and C. A similar observation was made when repeating the experiment with purified AAV9.

Our findings indicate that heat inactivation at 95°C is detrimental to AAV vg titration and DNAseI treatment only is sufficient for the removal of unpackaged DNA without affecting vg titers. In a next step, we aim to validate this ddPCR protocol and evaluate robustness, specificity, linearity, range, accuracy, precision, and quantification limits.

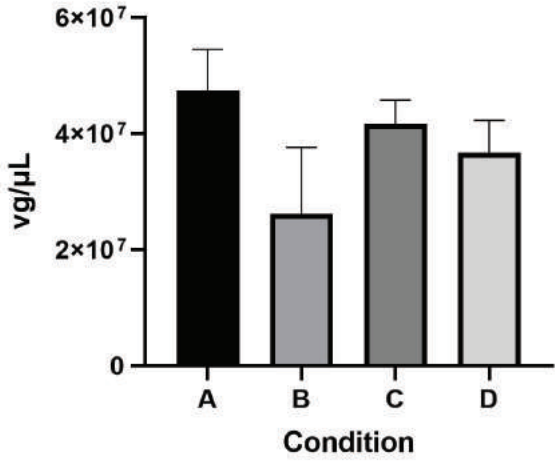

Figure 1. AAV2 viral genome titers after the following sample treatment conditions: (A) incubation with DNAseI only; (B) DNAseI incubation followed by EDTA inactivation, 72°C heat inactivation, proteinase K treatment, and finally 95°C heat inactivation; (C) the same as condition B but with a final heat inactivation at 72°C instead of 95°C (D) no sample pretreatment. N = 8

781 Adeno-Associated Viral (AAV) Vector-Mediated GLB1 Gene Transfer Reduces Substrate Accumulations in a Murine Model of GM1 Gangliosidosis

Yan G. Ni[1], Michael Gelb[2], Zachary Herbst[2], Catherine Vrentas[3], Elyse Messick[3], David A. Weinstein[1], Susan E. Browne[1], James M. Wilson[4], Christian Hinderer[4]

[1]Passage Bio, Inc., Philadelphia, PA,[2]Chemistry, Univ of Washington, Seattle, WA,[3]PPD, part of Thermo Fisher Scientific, Wilmington, NC,[4]University of Pennsylvania, Philadelphia, PA

Introduction: GM1-gangliosidosis (GM1) is a lysosomal storage disorder resulting from mutations in the galactosidase beta 1 gene (*GLB1*) leading to reduced β-galactosidase (β-gal) activity, neuronal degeneration, and developmental delays. Deficiency of β-gal gives rise to toxic accumulation of its substrates, GM1-gangliosides and other glycoconjugates with β-linked galactose including glycosaminoglycans (GAG, e.g., keratan sulfate) and O- and N-linked glycans (dp5 and A2G2'). Several of these β-gal substrates have been reported to be elevated in GM1 patients and in GLB1-/- mice. However, it is unclear how these substrates would respond to increases in β-gal activity. In this study, we examined the effect of restoration of β-gal activity through AAV-mediated gene transfer in GLB1-/- mice. **Methods and Results:** β-gal activity was measured with a fluorometric assay using a 4-methylumbelliferyl-β-D-galactopyranoside substrate. GM1-gangliosides, an endogenous GAG non-reducing end tetrasaccharide (from keratan sulfate), and glycans dp5 and A2G2' were measured by liquid chromatography-tandem mass spectrometry (LC-MS/MS). β-gal activity in CSF and serum samples from GLB1-/- knockout mice were <10% of those from the wild-type mouse samples. Conversely, concentrations of GM1-gangliosides in CSF and whole blood, the keratan sulfate tetrasaccharide, and O- and N-linked glycans (dp5 and A2G2') in whole blood and urine were elevated significantly in GLB1-/- mice compared to those in wild type mice. Further, we observed that a single intracerebroventricular injection of an AAV vector expressing human β-gal leads to reduction of GM1-gangliosides in CSF and whole blood and the keratan sulfate tetrasaccharide, dp5, and A2G2' in whole blood and urine. **Conclusion:** These findings demonstrate the potential therapeutic value of the AAV mediated-gene transfer approach and support the use of GM1-gangliosides, keratan sulfate tetrasaccharide, and glycans dp5 and A2G2' as pharmacodynamic biomarkers in clinical studies.

782 Early Development of *In Vitro* Potency Assays for Rare and Ultrarare Disease Gene Therapy Products

Elena E. Balkanska-Sinclair, Sara C. Potter

Ultragenyx Pharmaceutical, Woburn, MA

Gene therapies offer efficient treatments for variety of genetic diseases. Potency, as one of the critical quality attributes (CQAs), is a requirement for the successful release of a gene therapy product. Developing an in vitro potency assay can be a challenging and time-consuming process. In this study, we developed a potency assay to measure the expression of a therapeutic gene in vitro using a cell-based system. Multiple cell lines were screened to assess effective transducibility and expression of the gene of interest, utilizing a GFP-based imaging screen approach. Our assay demonstrated good sensitivity, repeatability and reproducibility, accuracy with recovery at all levels tested from 25-200% relative potency, and specificity for the intended gene of interest. The in vitro potency assay developed in this study is a valuable tool for the early development with the capability to be applied in the evaluation of other gene therapy products with minimal program-specific adjustments.

783 Development of a High-Throughput CUT&RUN Platform for Epigenomic Mapping of Rare Primary Immune Cells

Keith E. Maier, Matthew R. Marunde, Carolina P. Lin, Danielle N. Maryanski, Michael-Christopher Keogh

EpiCypher, Durham, NC

Understanding immune cell differentiation is central to gene and cell therapy research. Regulation of chromatin structure drives many of these processes, leading to the widespread application of chromatin accessibility (ATAC-seq) and transcriptional (RNA-seq) profiling for immune cell characterization. However, these assays often fail to provide mechanistic insight and can lack the granular detail required to define rare and/or novel immune cells (e.g. exhausted T cells). Epigenomic features - such as histone post-translational modifications (PTMs) and chromatin-associated proteins - mark distinct genomic compartments (i.e. promoters) and regulate chromatin structure, gene expression, and cell function. Mapping these features provides a rich context to study cell fate and has great potential for discovering

new biomarkers and drug targets. Notably, the traditional chromatin mapping technology (ChIP-seq) is impractical for immune cell studies due to poor sensitivity, high background, and low throughput. Sample processing methods for ChIP also vary and require substantial expertise, complicating its use in tightly controlled, multi-site studies. Here, we present a breakthrough CUT&RUN assay for rapid, ultra-sensitive profiling of FACS-sorted primary immune cells. Our workflow generates reliable profiles from <10,000 cells per reaction, and is supported by a rigorous optimization strategy, high-quality antibodies, and robust spike-in controls. Further, by automating our CUT&RUN protocol, we were able to increase throughput and standardize sample handling. The resulting workflow was applied at-scale in collaboration with ImmGen, a multi-site project building a comprehensive 'omic database of mouse immune cells. We have generated >1,500 epigenomic profiles from >100 different FACS-sorted primary mouse immune cell types, demonstrating the reliability of our process across diverse samples and labs. Our CUT&RUN approach allows researchers to fully leverage the epigenome to define cell identity. This technology has broad applications in cell and gene therapy research, including CAR T cells, Cas9/dCas9 off-target modifications, exhausted T cells, and induced pluripotent stem cells.

784 CD19-Targeted CAR T Cells Product Identity and Purity Flow Cytometric Method Development: An Analytical Quality by Design Focus

Michelle Tseng, Jorge Marques, Faylor Kym
Azzur Labs, Azzur Group, Hatboro, PA

CD19-targeted chimeric antigen receptor (CAR) T cell gene therapy is a novel, living drug type directed at CD19-expressed B cells in blood cancers. To meet regulatory quality standards, they require drug safety, purity, identity, strength, and potency to be demonstrated before the product can be released. We developed a fit-for-purpose, clinical polychromatic flow cytometric method that supports part of the CD19-targeted CAR T cell drug release criteria for product identity and purity. This method can be used to evaluate process-related cellular impurities. Our method applies the analytical quality-by-design (AQbD) concept which is deeply rooted in various International Conference on Harmonisation (ICH) and United States Pharmacopeia (USP) guidelines. For instance, the associated ICH Q8 (R1), Q9, Q14, and USP 1220 all suggest a AQbD approach to analytical method development for pharmaceutical drug development. Unlike other biologics, gene therapy drug quality is susceptible to varied levels of cellular compositions and functions of incoming apheresis materials and manufacturing process changes. As a result, analytical methods used in such product release evaluations must be sensitive and robust enough to provide meaningful assessments for the process intermediates and product of gene therapies. By the systemic AQbD approach, we followed a series of steps in our method development which can include: the establishment of analytical target profile (ATP); technology selection; identification of critical method attributes (CMAs) through a risk assessment; method development and optimization; method operable design region (MODR); and method qualification. Through this approach, we identified and verified critical quality attributes (CQAs) that can affect the drug potency. In addition, we developed and qualified this method using frozen CAR-T cell drug product lots and cell lines on a BD FACS Lyric™ cytometer to accommodate a high demand for analytical testing. Finally, our results demonstrate that the developed method is reproducible, sensitive, robust, and compliant, appropriate for product lot release testing. We will continue to collect more data to establish drug product specifications for the CQAs.

785 Predictive Assays for Modeling Foreign Body Response to Encapsulated Cell Therapies

Mandar Bawadekar[1], Mason McClatchey[1], Kathleen Barrett[1], Paul Nguyen[1], Jamie Kady[2], Catherine Kooyomjian[2], Matthew Buchanan[1], Chris Sparages[1], Marissa Donovan[1], Jillian Higgins[1], Charina Ortega[1], Sarah Yuan[1], Olivia Kelly[1], Michael Brehm[2], Joseph Tumang[1], Philip G Ashton-Rickardt[1]
[1]Sigilon Therapeutics, Cambridge, MA,[2]UMass Chan Medical School, Worcester, MA

The Foreign Body Response (FBR) to encapsulated cell therapies poses a great challenge to developing a long term durable therapeutic product. The severity of this response is attributable to: a) the nature of the biomaterial; b) the secretome profile of the cell and; c) the immunogenicity of the protein cargo of the encapsulated cells. Sigilon's Shielded Living Therapeutic™ (SLTx) technology uses Afibromer™ conjugated alginate spheres that are designed to be biocompatible and to avoid FBR thus allowing longer therapeutic durability. We developed a set of *in vitro* and *in vivo* assays designed to guide us in selecting more durable configurations for our therapeutic programs. Macrophage attachment, the initiating step in the FBR process, is influenced by the nature of the biomaterial and the inflammatory secretome of encapsulated cells. Using a sequence of secretome analysis, coupled with a high-throughput *in vitro* macrophage attachment assay, we are able to faithfully model this process and de-risk our product *in vitro*. Then, using a humanized mouse model that faithfully recapitulates the FBR process we can predict the FBR potential of our encapsulated cell therapy. These predictive assays guide us in the development of a durable allogeneic cell therapy product.

786 Eliminating Challenges in Lentiviral Vector Characterization with Capillary Electrophoresis

Priyanka Sarkar[1], Hadi Maktabi[2], Chris Heger[1]
[1]Applications Science, Bio-Techne, San Jose, CA,[2]Bio-Techne, San Jose, CA

Lentiviral vectors (LVV) have become a prominent and popular gene delivery system for both in vivo and ex vivo therapies. It is crucial to identify, characterize, and quantify these LVV particles to ensure quality, safety, efficacy, and to meet all regulatory requirements. In this work, we leveraged the Maurice CE-SDS platform to develop a robust method for LVV analysis. We show the method can be used for LV identity and viral titer. Comparing different LV vendors, unique but similar profiles were obtained with the CE-SDS method. Assessing and characterizing the capsid core protein p24 offers an estimation of

LVV quantitation as well as transduction efficiency. Using recombinant p24, we show accurate viral titer estimation. Together, the LV method provides a rapid and accurate analysis of lentiviral products.

787 Development and Comparative Assessment of a Rapid, High-Throughput Method for Accurate Quantification of Host Cell DNA Impurities in Final Drug Product and Process Intermediates

Jesse Granados
Capsida Biotherapeutics, Thousand Oaks, CA

Biologics manufactured in cell lines carry inherent risk of incorporating host cell material in the drug product. In particular, elevated levels of residual host cell DNA (hcDNA) contaminants increases oncogenic risk and may lead to a systemic induction of the immune response. The World Health Organization and European Pharmacopoeia have established a guideline for the acceptable level of hcDNA (<10 ng per dose) in biologics. As such, regulatory agencies have focused on quantifying and characterizing hcDNA in gene therapy products as a critical parameter for product safety. Therefore, a highly sensitive, accurate, and robust method of hcDNA quantitation provides valuable information during process development and is essential as a safety and quality metric of the final drug product. In this work, we report a robust, high throughput qPCR method capable of accurately quantifying total and encapsidated hcDNA in all process intermediates and final drug products within two hours. When compared to a validated, commercial residual hcDNA qPCR kit, the assay exhibits improved accuracy (>90%), specificity/sensitivity (6 log dynamic range, LLOQ-30 fg), and reproducibility (<20% inter-assay RSD) in several unrefined in-process matrices. We have shown that our developed residual hcDNA qPCR assay is suitable to reliably quantitate low levels of host cell impurities without extensive sample processing for intermediate and final drug product samples.

788 Evaluation of a Synthetic Regulatory T Cell Platform Using a Suite of Analytical Methods and Preclinical Models

Ashley Mahne, Jesus Banuelos, Andrew Tremain, Shriya Sethuraman, Shairaz Shah, Candice Gibson, Simone Sandoval, Jazmin Bravo, Kelsey Phipps, Baden Dense, Jeanne Flandez, Jennifer Zeng, Dominic C. Borie, Jeffrey Greve, John Lee, Peter Beemiller, Charles Kaplan, Brandon Kwong
Kyverna Therapeutics, Emeryville, CA

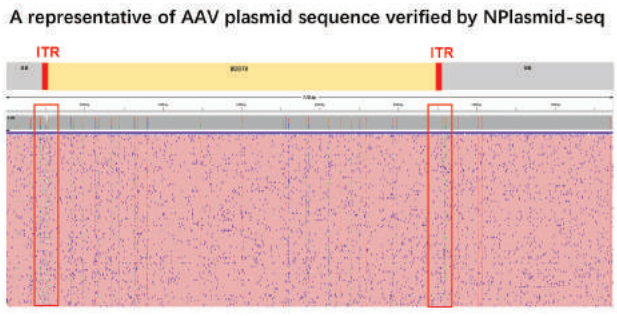
Introduction: Regulatory T cell (Treg) therapy is a promising avenue for the treatment of autoimmune diseases. Tregs exert potent, polyfunctional immune suppression and have the potential to reset immune tolerance in a variety of inflamed tissues. Two major challenges in translating Treg cell therapies into the clinic have been their polyclonal repertoire and the limited number of purified, stable Tregs that can be isolated from disease patients, expanded, and manipulated ex vivo. Synthetic regulatory T cells (synRegs) derived from abundant $CD4^+$ T cells are an attractive alternative with more facile manufacturability. To ensure the safety and efficacy of any Treg or synReg therapy in the clinic, deep characterization of its functionality and stability is essential. Here, we report on the analytical characterization of a novel chimeric antigen receptor synReg platform (CAR-synRegs). **Methods**: CAR-synRegs or synRegs were generated by transducing human naïve $CD4^+$ T cells with FOXP3, along with or without a 2^{nd} generation CAR targeting a tissue antigen, encoded in a single lentiviral vector. Transduced cells were expanded in vitro to attain clinically relevant doses using a GMP-adaptable process. In vivo stability and suppressive efficacy of polyclonal human synRegs were evaluated in a xeno-GvHD mouse model. To further mimic the inflammatory signaling environment likely to be experienced by CAR-synRegs in a disease patient, CAR-synRegs were exposed to homeostatic or pro-inflammatory conditions in extended cultures in vitro, and restimulated in a polyclonal or CAR-specific manner. Following culture under such conditions, CAR-synRegs were evaluated for their ability to suppress effector T cell responses and dendritic cell function, maintain stable CAR and FOXP3 expression, and secrete pro- or anti-inflammatory cytokines. Moreover, synRegs were profiled for both Treg-associated gene and protein expression by RNAseq, DNA methylation analysis, and flow cytometry. **Results:** Deep analytical characterization demonstrated that CAR-synRegs express both a Treg-like profile and functional suppressive activity. CAR-synRegs maintained high FOXP3 expression and suppressed effector T cell responses and DC functions in vitro, while polyclonal synRegs potently inhibited disease progression in vivo in the xeno-GvHD model. However following exposure of CAR-synRegs to inflammatory factors, CAR engagement induced the increased production of Th1 effector-associated cytokines, indicating an opportunity to further reprogram CAR-synRegs for maximal safety and efficacy. Thus CAR-synRegs were re-engineered with the modular addition of genetic and non-genetic (small molecule) modifiers, and evaluated using the same suite of analytical methods to identify modifiers that improved both the functional and safety profiles of CAR-synRegs. These modifiers increased long-term FOXP3 stability, upregulated the expression of Treg-associated functional receptors, and/or modulated the pro- vs anti-inflammatory cytokines secreted in response to CAR activation and inflammatory conditioning. **Conclusions:** The risk of Treg instability is a concern that is applicable to both synthetic or naturally-derived Treg therapies. These results highlight our ability to identify potential limitations of Treg therapies and address such risks via genetic and non-genetic reprogramming approaches to enhance the efficacy and safety profile of a Treg platform.

789 NPlasmid-seq: A Quality Control Toolkit for Full-Length Plasmids Enabled by Nanopore Sequencing

Yidan Sun[1], Zhixue Yang[1], Zhikang Zhang[2], Feng Zhang[1], Huayu Li[2], Jianping Zhang[1], Xiaobing Zhang[1]
[1]State Key Laboratory of Experimental Hematology, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Peking Union Medical College, Tianjin, China,[2]College of Computer Science and Technology, China University of Petroleum (East China), Qingdao, China

In current gene therapy, the prevailing delivery vectors are engineered viruses produced in packaging cells by transfecting plasmids. Sequence verification and contamination control of plasmids are instrumental to vector quality assurance. The short reads of Sanger sequencing and

Illumina NGS pose a challenge in piecing together the full plasmid sequence, particularly for vectors containing repetitive fragments. Furthermore, these DNA amplification-based sequencing approaches often fail to read through strong secondary structures like AAV ITR. In addition, no documented evidence has shown that the first two-generation methods can confidently identify small contaminants (e.g., 5%). To ensure vector authenticity during plasmid manufacturing and vector packaging, the gene therapy field calls for a protocol to determine the full length and to detect trace amounts (e.g., 0.1%) of contaminated plasmids. Nanopore sequencing (NP-seq) technology reads ultralong sequences at a single molecule level, providing an opportunity to resolve such challenges. **Methods**: Here, we introduce the experimental procedure and bioinformatics pipeline to achieve that goal. To prepare for the NP-seq library, we first linearized plasmids using RNPs of Cas9-sgRNAs targeting the plasmid backbone, followed by sequencing using R9.4.1 flow cells on a MinION. In addition, over ten sgRNAs were designed to enable pooled sequencing of different batches. To streamline data analysis, we developed a python-based pipeline termed NPlasmid-seq, which outputs demultiplexed reads, contaminated plasmids, computed consensus sequences, and vector visualization results in one folder. A stretch of DNA flanking the CRISPR cleavage site was used to demultiplex the pooled reads. **Results**: Plasmid-seq could determine full-length lentiviral vector plasmids over 10 kb, adenoviral plasmids of 30-35 kb, AAV plasmids with the ITR structure, and mRNA in vitro transcription (IVT) template plasmids with consecutive 90 adenine bases (A90). When a reference is not provided, the consensus computed with over 100 reads was around 99.5% identical to the known sequence, while inputting a reference leads to correct alignment with 99.9% of sequences. To determine possible plasmid contamination, NPlasmid-seq first teased out reads with indels of over 10 nt and binned to a "Warning Data" collection, followed by aligning with the reference sequence library. To mimic plasmid contamination, we manually doped with 0.1% of an unknown plasmid. To decrease the false discovery rate, we called contamination only with the support of at least three reads. We found that over five reads of contaminants were sufficient to parse out its identity at 99% confidence. **Conclusion**: NPlasmid-seq, in its current version, cannot replace Sanger sequencing due to the high error rate of NP-seq. However, it provides a powerful toolkit to determine full-length plasmids and minute amounts of potential contaminants. Therefore, NPlasmid-seq offers a full plasmid sequencing and data analysis pipeline that would find its application in vector cores or gene therapy companies.



790 Establishing GMP Compliant Adenovirus Serotype 35 Manufacturing Process

Toshihiko Okazaki[1], Hiroyuki Mizuguchi[2]
[1]Osaka University Hospital, Suita, Japan,[2]Osaka Univ. / NIBIOHN, Suita, Japan

As gaining global recognition of gene therapies for its remarkable clinical benefits in a variety of medical applications, research and development of viral vectors as medical applications have become considerable interest. Among the different types of viral vectors, adenoviral (Ad) vectors have been extensively studied and used for a long time in medical care, especially recent worldwide attention due to the recent approvals of Ad vector-based COVID-19 vaccines. We are developing a novel adenovirus serotype-35 (Ad-35), to see if it could be useful as a vaccine (non-replicating vector) or oncolytic virus. So far GMP compliant manufacturing process of Ad-35 has not been established in the world.This time, we challenged to establish Ad-35 vector GMP compliant manufacturing process development for the usage in the investigational clinical trial. Based on the pre-conditioning analysis of optimizing culture condition using the suspension HEK293 cell line with serum-free culture medium, a closed mass cell culture system was constructed by transfer to the shaking back-type closed culture system. Final 5,000 mL of suspended HEK293 cells Ad-35 vector-infected were obtained. Virus-infected whole culture cells were lysed to obtain viruses, following further purification and concentration steps were performed to get crude harvest. Subsequently, target fraction separation by ion exchange membrane chromatography was performed to capture Ad-35 vector, resulting in final 50 mL viral-contained products collected. We could identify the critical process parameters in the up-stream (closed mass cell culture system) and down-stream (virus purification process). These clinical developments would suggest an excellent path to construct a GMP-compliant viral investigational drug production platform.

791 Clinical-Scale Production of Lentiviral Vectors at a New Academic cGMP Facility

Cesar Moncada, Andrew Liermann, Charles Lewis, Jeffery Medin, William M. McKillop
Medical College of Wisconsin, Milwaukee, WI

Lentiviral vector (LV)-mediated gene delivery has shown clinical promise in the gene and cell therapy field. LVs offer a high rate of transduction into many cell types, the ability to transduce non-dividing cells, stable gene integration, and a reduced risk of insertional mutagenesis when compared to gamma-retroviruses. However, the production and purification of high-quality LVs for clinical trials remains challenging. The MCW/BCW GMP Vector Production Facility's mandate is to produce high-titer, clinical-grade LV for use in early-stage trials at the Milwaukee Regional Medical Center (MRMC). Herein we describe a method to scale-up production of high-titer LVs that are capable of transducing multiple cell types under GMP conditions. We package our LV using HYPER technology, a commercially available, fully closed and disposable system composed of multiple layers of a gas-permeable, tissue culture-treated, growth surface. Following packaging, we purify LV by post-harvest clarification and Mustang Q anion-exchange membrane chromatography. Scale-out experiments have provided encouraging recovery yields from

clarification (83%) and Mustang Q chromatography (67%) resulting in a 1000-fold volume reduction with excellent viral recovery (60-70% of starting input LV). The chromatography eluate is subsequently diluted and concentrated using tangential flow filtration (TFF) and treated with Benzonase endonuclease (50 U/ml) at 37C. TFF is then repeated to further concentrate the LV down to 200 ml of deliverable product. To evaluate compliance with current FDA guidance for clinical application, we analyzed samples from our production and purification process to assess LV purity and titer. We report functional titers between 1.3 x 10^7 TU/mL and 2.2 x 10^8 TU/mL for clinically relevant vectors. Our purification method results in minimal endotoxin detected (<100 EU/ml). Furthermore, post purification residual plasmid DNA, host-cell DNA, and host-cell protein were reduced >98%, >99%, and >98%, respectively. The HYPER LV packaging strategy, Mustang Q chromatography, and TFF purification regimen described here is a practical method for LV scale-up to early-stage clinical trial volumes using affordable disposable laboratory supplies.

792 Cell Line Developement for High-Titer Lentiviral Vector Production

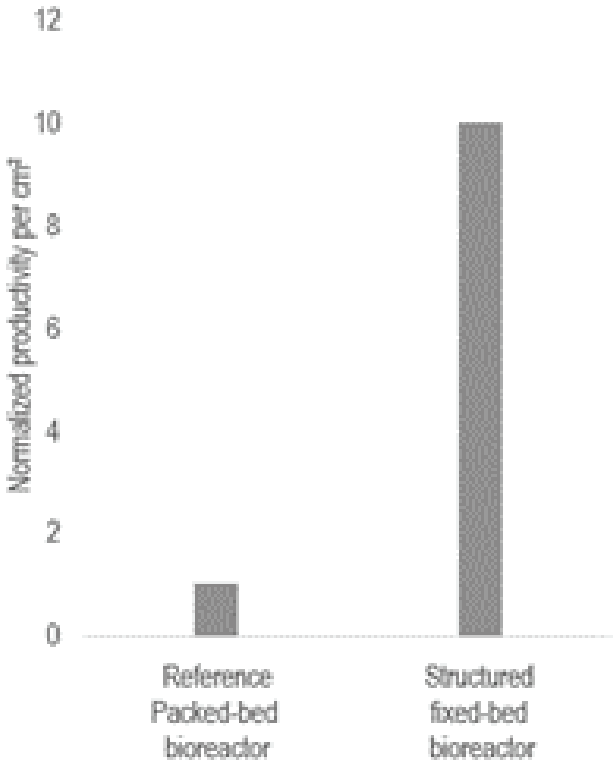
Hairui Yang, Weiran Shen, Han Gao
OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China

Lentiviral vector (LV) is an important tool in gene delivery and gene therapy. Current production of lentiviral vectors is based on multiple plasmids co-transfection of adherent HEK293T cells in monolayer flasks. However, the cell population is heterogeneous and not achieving ideal yield. It is possible to improve the packaging capacity of production cells to increase the yield of lentiviral vectors per cell. In this study, we report a method to produce LVs in high yield by developing monoclonal HEK293T cell line. This method can sort out single HEK293T cell with high transfection efficiency and seed the cell into one well of a plate. The system uses low fluidics pressure, resulting in a higher frequency of wells containing viable and single cell with high transfection efficiency. Ten cell lines developed from this system were finally selected. Using the selected HEK293T cell lines, LVs production was tested in 10-layer cell factories and the vector titer was quantified. Four cell lines demonstrated a double yield comparing with the original cell line. One cell line was further tested by packaging different GOI, there was 2-4 folds improvement in yield across different GOI packaging.

793 High-Performance, Scalable Lentiviral Vector Manufacturing Workflows Supporting Continuous Processing

Tania Pereira Chilima
Univercells, SA, Gosselies, Belgium

Due to the clinical successes associated with gene-modified cell therapies such as CAR-T, and given rising interest for in vivo gene therapy applications, the demand for lentiviral vectors (LV) is expected to continue growing significantly in the coming years. LV manufacturing however presents unique challenges, due to the highly sensitive nature of the product and the inherent complexity of its manufacturing process. In addition, as required production throughput can vary significantly with dose size, target indication and development stage, technologies providing flexibility on scale while maintaining reproducibility are a key requirement for developers and manufacturers. While much effort has been invested in developing manufacturing workflows based on suspension processes in stirred-tank reactors (STR), this approach remains associated with several limitations. Indeed, key parameters such as shear, mixing and gas exchange cannot be simultaneously maintained across scales, constraining developers and impacting the reproducibility and cost effectiveness of manufacturing processes. In this session, the speaker will present a streamlined platform designed to enable flexible, scalable LV manufacturing. Several cases studies will be highlighted, demonstrating how structured fixed-bed technology can address specific challenges associated with LV production in both adherent and suspension platforms. The speaker will illustrate how a low shear, homogenous bioreactor environment leads to a >10-fold increase in productivity, and present data supporting maintained performance across scales. Application of perfusion processes and continuous processing approaches will be explored, laying out a scalable, cost-effective workflow for clinical and commercial stage LV manufacturing. Finally, the speaker will touch on considerations regarding intensified seed train generation for large-scale production, with the presentation of automated, closed system addressing key challenges associated with this critical step.Figure 1. Increased LV functional titre in a structured fixed-bed bioreactor. Lentivirus production in reference (packed-bed bioreactor process) compared to a structured fixed-bed bioreactor process/ Normalized functional titre (TU) is displayed, relative to the reference process



794 LentiVEX Packaging Cell Line v2.0 Yields Comparable LVV Titres to the 4-plasmid Process

Marie Mulet[1], Meenakshi Raghunath[1], Matthew Tridgett[1], Cristina Fernandez-Diaz[1], Maria Ababi[1], Richard Parker-Manuel[1], Yiyu Dong[2], Man-Shiow Jiang[2]
[1]OXGENE, Oxford, United Kingdom,[2]WuXi Advanced Therapies, Philadelphia, PA

Current lentiviral vector (LVV) manufacturing approaches primarily use fully transient and adherent processes which present challenges of robustness, scalability, and high cost-of-goods. To address these, we have developed suspension cell lines for transient, semi-stable and stable LVV manufacture. Tet-regulated VSV-G and Gag-Pol, and constitutive but codon optimised Rev lentivirus packaging components were randomly integrated into WXATUS0028 suspension HEK293 cell line. Using a fully traceable, animal component-free and high-throughput cell line development process, the top LentiVEX Packaging cell line v2.0 was identified. It only requires transfection of the LV genome plasmid with doxycycline induction to achieve LVV yields of 2 x 10^8 TU/mL (with eGFP as Gene of Interest), comparable to the four-plasmid process with WXATUS0028. Long term production stability of the packaging cell line was assessed and LVV titres were consistent (> 1.5 x 10^8 TU/mL) for 27 passages without any selective pressure applied. Genetic stability and location of the integrated genes are currently being assessed by ddPCR, NGS and TLA analysis. Therapeutically relevant GOIs of sizes ranging from 0.05 to 4.4 kb were also tested, and the packaging cell line demonstrated higher yields than the WXATUS0028 baseline when GOI > 1.7 kb. Scale-up vector production and process development with the packaging cell line are ongoing, with the Master Cell Bank (MCB) being generated for GMP-standard vector manufacturing. With a reduced plasmid cost and a simplified transfection process, the LentiVEX Packaging Cell Line v2.0 is a flexible platform to support both early-phase discovery studies with easy screening of multiple GOIs and large-scale LVV manufacture.

795 ADEVO: Proof-of-Concept of Adenovirus Directed EVOlution by Random Peptide Display on the Fiber Knob

Erwan Sallard[1], Eric Ehrke-Schulz[1], Nissai Beaude[1], Adrian Westhaus[2], Marti Cabanes-Creus[2], Leszek Lisowski[2], Anja Ehrhardt[1]
[1]ZBAF, Witten/Herdecke University, Witten, Germany,[2]Children's Medical Research Institute, Westmead, Australia

Introduction: Directed evolution is a method of vector development consisting in the generation of a random library of vector variants, followed by the selection of improved variants according to pre-defined selection criteria. Directed evolution already led to numerous innovations in Adeno-associated virus or Lentivirus vectors but yielded few successes in Adenovirus vector (AdV) development until now. This was mainly due to technical difficulties in constructing large random libraries. Meanwhile, AdVs clinical applications as gene therapy or oncolytic vectors are still hampered by the predetermined tropism of natural serotypes. To overcome this challenge, we hypothesized that validated vector retargeting technologies such as peptide insertions can be incorporated into the AdV toolbox. Here we designed novel Adenovirus Directed EVOlution (ADEVO) protocols for AdV retargeting, based on the insertion of random peptides in the fiber knob domain. To assess and optimize the protocols, we constructed libraries based on the frequently used adenovirus type 5 (Ad5) and tested if we could select variants able to infect A549-ΔCAR cells, that are non-permissive for natural Ad5. Methods: In protocol 1, random oligonucleotides were inserted through NEBuilder homologous recombination inside a plasmid containing the AdV fiber gene, which was then transferred to a full AdV genome. In protocol 2, the genome library was built in a single step through direct insertion of random oligonucleotides into the AdV genome. In both protocols, the initial vector library was built by transfection of the genome library into HEK293 cells. Variants with improved tropism for A549-ΔCAR cells were then selected by serial passage of the libraries on these cells. Library complexities were estimated by NGS. Results: Cross-packaging is a process by which capsids do not package their corresponding genome. This can lead to selection failure in directed evolution. Using co-transfections of wild-type and fiber-deficient adenovirus genomes, we determined that the cross-packaging rate of adenoviruses remained below 3% when applying up to 5000 transfected genomes per cell, a dose at which high vector titers can be produced. Therefore, cross-packaging should not hamper library construction and selection.ADEVO protocols 1 and 2 enabled the construction of high complexity genome and vector libraries, with at least **2.7e5 and 3.9e5 unique variants** in the respective initial vector libraries. Vectors able to efficiently infect A549-ΔCAR cells were enriched during the selection phase, while non-functional variants containing stop codons were eliminated. In subsequent steps, enriched variants will be purified and characterized in detail. Conclusions: ADEVO, our novel directed evolution workflow for Adenoviruses, facilitates the construction of highly diverse variant libraries and the selection of improved vectors with user-friendly protocols. We expect that this new technology can contribute to the development of clinically relevant adenoviral vectors with more specific tropism and higher transduction ability in target cells.

796 Vector Manufacturing Processes for Gene Therapy

Margherita Neri[1], Giuliana Vallanti[2]
[1]AGC Biologics, Milano, Italy,[2]AGC Biologics, Bothell, WA

AGC biologics is a leading global CDMO, providing world-class development and manufacture of mammalian and microbial-based therapeutic proteins, plasmid DNA, viral vectors and genetically engineered cells. Adeno Associate Vectors (AAV) and Lentiviral vectors (LVV), produced with transient transfection in HEK293 and HEK293T cells are extensively used for genetic modification in gene therapy for *ex-vivo* and *in-vivo* treatments. An important manufacturing challenge is the availability of a efficient and scalable off-the-shelf vector production processes. To address this goal AGC Biologics is developing different systems for AAV and LVV production at large scale, in adhesion and suspension, flexible to be adapted to different GOI and AAV serotypes. Adherent platforms exploit Pall iCELLis® fixed-bed disposable bioreactors. Suspension platforms are based on proprietary cell lines in a culture system without animal derived reagents in stirred tank bioreactors. AAV manufacturing process in adhesion has been scaled up on 333m^2 bioreactors with the production of both retained and released serotypes starting from

70L and 480L of bulk lysate respectively. We obtained a productivity at full scale of 1.6E+09 VG/cm^2 for a retained serotype and 1.2E+10 VG/cm^2 for a released serotype . DSP includes concentration step by TFF, affinity chromatography, polishing by AEX to enrich in full/empty particles, further concentration and diafiltration steps and final sterilizing filtration. Total DSP yield ranges between 30% and 40%. AAV production in suspension has been performed at 50L pilot scale in Sartorius Biostat STR bioreactor obtaining 1.1E+11 VG/mL with 70% ratio full/total and a yield ranging between 20% and 30%. Scale up to 200L will be performed in 3Q 2023 and the process is ready to be scaled up to 2000L. AGC Biologics (former MolMed) has a long lasting experience in the manufacturing of LVV for clinical and commercial phases. As evolution of the well-established adherent GMP 48L CF process we developed a robust, scalable, high quality and quantity processes for the industrial scale production of LV vectors performed in iCellis500 bioreactor 133m^2 obtaining 200L of bulk vector with an average titer of 3x10^7 TU/mL. DSP foresees DEAE chromatography, concentration and diafiltration by HF and final sterilizing filtration with an overall yield of 20-30%. LVV manufacturing suspension process has been developed at scale down and confirmed at 50L scale obtaining 5.7x10^7 TU/mL in the bulk vector. Downstream process was designed in order to accommodate larger volumes of vectors from bioreactor. Single use Tangential flow filtration and DEAE chromatography steps were successfully implemented, with good removal of process related contaminants and no detrimental impact on vector infectivity and stability. Freshly released affinity resins for LVV are under evaluation in order to increase purity and quality of final vector for in-vivo application. AAVs and LVVs have been characterized with an orthogonal strategy including Viral Genome/Particles quantification, infectious viral titer, core protein characterization and process related impurities demonstrating high potency and quality suitable for ex-vivo and in-vivo applications. Moreover, the possibility to leverage the analytical platform already in use for the GMP process accelerates transition from development to GMP clinical and commercial productions.

797 A Scalable, Suspension-Based Platform to Produce Virus-Like Particles (VLPs) for *In Vivo* Gene Therapy

Deborah Pano, Greg Bremer

Ensoma, Boston, MA

Helper dependent adenovirus (HDAd) is a virus-like particle (VLP) capable of safely delivering large payloads *in vivo*. HDAd vectors are completely devoid of viral coding sequences, thus require a helper virus and an engineered HEK293 cell line to replicate. The established production process utilized an adherent cell line grown in serum-containing medium, which is more challenging to develop and scale compared to suspension processes. The engineered HEK293 cell line was weaned off serum and adapted to grow in suspension culture. Exponential growth and successful HDAd production were demonstrated in shake flasks. Ambr15 experiments were conducted to screen and optimize critical process variables for HDAd production. Shake flask and Ambr15 data demonstrated comparable per cell HDAd production in suspension culture compared to that of the original cell line. Using Ambr15 data, the suspension process was scaled to 2L benchtop bioreactors. Bioreactor HDAd production was comparable with Ambr15 data, demonstrating process scalability.

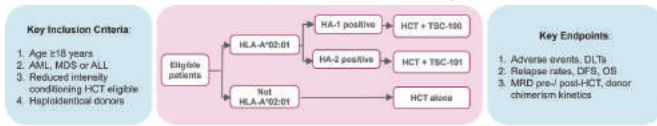
798 Trial in Progress: A Phase 1 Trial of TSC-100 and TSC-101, Engineered T Cell Therapies That Target Minor Histocompatibility Antigens to Eliminate Residual Disease After Hematopoietic Cell Transplantation

Monzr M. Al Malki[1], Hyung C. Suh[2], Alla Keyzner[3], Aasiya Matin[4], Yun Wang[5], Nina Abelowitz[5], Jim Murray[5], Gavin MacBeath[5], Debora Barton[5], Shrikanta Chattopadhyay[5], Ran Reshef[6]

[1]City of Hope, Duarte, CA,[2]Hackensack Medical Center, Hackensack, NJ,[3]Mount Sinai, New York, NY,[4]Karmanos Cancer Institute, Detroit, MA,[5]TScan Therapeutics, Waltham, MA,[6]Columbia University, New York, NY

Engineered T cell therapies such as chimeric antigen receptor T (CAR-T) cell therapies have transformed the treatment of lymphoid malignancies but have not yet proven effective in myeloid malignancies. Allogeneic hematopoietic cell transplantation (HCT) remains the best curative option for these malignancies but ~40% of patients relapse post-HCT with ~90% mortality due to residual disease post-HCT. A key challenge in these malignancies is identifying the right antigens for T cell targeting. Cancer-associated antigens have heterogenous expression enabling rapid escape of malignant cells with low antigen expression while targeting lineage-specific antigens without a clear distinction between malignant from normal myeloid cells carries the risk of prolonged neutropenia. A potential solution is to target minor histocompatibility antigens (MiHAs) that are highly and homogenously expressed on all hematopoietic cells and are mismatched between patients undergoing HCT and their donors. These mismatches enable T cells to selectively eliminate residual patient hematopoietic cells, normal or malignant, leaving donor cells untouched. TScan has developed allogeneic donor derived T-cell products TSC-100 and TSC-101, targeting MiHAs HA-1 and HA-2 respectively, both presented on HLA-A*02:01. By choosing HCT patients who are HLA-A*02:01 positive (>98% of whom are either HA-1 or HA-2 positive) and donors who are either HLA-A*02:01 or MiHA negative, TSC-100 or TSC-101 can eliminate residual patient-derived hematopoietic cells after HCT to prevent disease relapse. Study NCT05473910 is a multi-center, multi-arm, non-randomized controlled Phase 1 umbrella study evaluating the feasibility, safety and preliminary efficacy of TSC-100 and TSC-101. Inclusion criteria include adults with AML, MDS or ALL eligible for reduced intensity conditioning-based haploidentical donor transplantation from HLA or MiHA mismatched donors. HLA-A*02:01-positive patients undergo HA-1/ HA-2 testing and are assigned to either TSC-100 or TSC-101 treatment arms in addition to standard HCT. HLA-A*02:01-negative patients in the control arm receive standard HCT alone. Upon count recovery after HCT, patients in the treatment arms receive either TSC-100 or TSC-101, administered as a single or two doses. Primary endpoints include adverse event profiles and dose limiting toxicities. Secondary end points include relapse rates, disease-free survival and overall survival. Exploratory endpoints include surrogates of efficacy

such as minimal residual disease (MRD) rates and donor chimerism rates and kinetics. MRD is measured before HCT, after HCT and after T cell therapy using a combination of flow cytometry and next-generation sequencing (NGS) that detect MRD with greater sensitivity than either assay alone. Donor chimerism is measured by standard STR-based and novel high-sensitivity NGS-based assays to quantify residual patient-derived hematopoietic cells. Together these assays measure elimination of residual patient hematopoietic cells, malignant or normal, and provide early evidence of biological activity.



799 Navigating the EU Clinical Trial Regulation (536/2014): Key Considerations for Gene Therapy Medicinal Product (GTMP) Developers

Claire Marasco, Ashley Shay, Christopher J. Shilling
Forge Biologics, Grove City, OH

As of January 31st, 2023, all new EU clinical trial applications (CTAs) must be submitted under the EU Clinical Trial Regulation (CTR) (535/2014) and via the Clinical Trials Information System (CTIS) portal. The regulation was created to prioritize the rights, safety, dignity, and well-being of clinical trial participants while simplifying and harmonizing the submission of CTAs and conduct of clinical trials in the EU. In the first 11 months of CTR implementation, only 4 clinical trials evaluating gene therapy medicinal products (GTMPs) have a decision out of 214 total clinical studies with a decision (EMA/2/2023, 31 January 2023, edition 9). It is expected that submissions for GTMPs and all clinical studies will accelerate in the next year with the requirement to submit initial CTAs under the CTR. Given the lack of precedent for GTMP developers, we have identified several key issues to consider when strategizing an EU clinical trials approach under CTR. Issues directly related to the CTR include member state concerned selection strategy, the management of auxiliary medicinal products, navigation of transparency requirements, and management of review and modification procedures. Other issues impacting CTR strategy include timing and expectations for EU Qualified Person interactions, genetically modified organism application considerations, and in vitro diagnostics considerations. In this presentation, Forge Biologics (Forge) will discuss potential solutions for GTMP developers to navigate these key issues. Forge continues to progress its own therapeutics programs in the EU and will use this experience to support our clients in the navigation of the CTR environment.

800 A Rollercoaster of High's and Lows; Learning from One Patient's Journey to CAR-T

Kristina Reeder[1], Caroline Norwood[1], Loren Caldwell[1], Chris A. Learn[2], Rachel Smith[1]
[1]Parexel, Newton, MA,[2]Parexel, Durham, NC

The diagnostic and treatment journeys leading up to consideration of cell and gene therapies, such as CAR-T, are significantly varied from person to person. When it comes to clinical trials, cell and gene therapies are typically studied in patients who have already had a long diagnostic and treatment journey and are at the point where they have exhausted all other care options. So what can we learn from one patient's journey? The team conducted a patient insights project to provide a deeper understanding of awareness, motivations, hesitations, and general experiences regarding a patient's journey before, during and after gene/CAR-T therapy for their cancer that can guide our strategies related to cell and gene therapy clinical trials. During this project, we performed an in-depth interview with representative patients who had received CAR-T cell therapy. The patient was diagnosed with supraclavicular lymph node stage 2 in 2011 and initially underwent 6 cycles of R-CHOP chemotherapy. In 2015, the patient was diagnosed with extra nodal Waldeyer's Ring and underwent further treatments with R-ICE, intrathecal methotrexate and head and neck radiation. Treatment options had limited success and the patient developed a number of severe side effects from their disease and treatments, including sepsis, severe dysphagia with mouth ulcers leading to significant weight loss. The patient's final treatment option per standard of care was allogenic transplant, however, no match was found. The patient became aware of CAR-T cell therapy clinical trials through a patient community, and as a last resort sought to enroll in a trial. Eventually, the patient was only accepted onto a trial in 2016 as a participant had died. As a study participant, the patient shares with the Patient Insights team what it was like to navigate a barrage of complex medical information, and make decisions with implications far beyond what is comprehendible for people who haven't been patients. As a last resort option, the journey through CAR T therapy was physically and emotionally exhausting - but found herself at the end, in remission but unsure of what her future would look like. What can we learn from the patient journey that may better the way we conduct clinical research? By shifting our focus from product led, to patient led drug development, we can help enhance the patient experience and ultimately improve patient outcomes.

801 One-and-Done Gene and Cell Therapy for Familial LCAT Deficiency Using LCAT Gene Transduced Human Adipocytes

Masayuki Aso
CellGenTech, Inc, Chiyoda-ku, Japan

Mutations in the gene encoding lecithin: cholesterol acyltransferase (LCAT) cause familial LCAT deficiency (FLD) characterized by severely lowered HDL-cholesterol, corneal opacities, hemolytic anemia, and renal disease. The prognosis for FLD is unfavorable, and patients finally develop renal failure. Enzyme replacement therapy is not currently available for this disease. The use of proliferative preadipocytes is advantageous in ex vivo gene therapy. After liposuction of fat, subsequent collagenase treatment, and floating centrifugation, preadipocytes can be readily prepared. The resulting preadipocytes have a highly proliferating rate that allows high transduction efficiency of the foreign genes and obtaining many cells for implantation. Once implanted, the cells undergo final differentiation into adipocytes that are highly stable in the body and have high secretion potential. To treat FLD, we performed first-in-human autologous implantation of genetically modified adipocytes (GMAC) expressing LCAT (LCAT-GMAC) into a patient with FLD. This first-in-human autologous implantation of LCAT-GMACs was shown to be safe by evaluating

adverse events. The LCAT-GMAC implantation increased serum LCAT activity by approximately 50% of the baseline and sustained over several years. Consistent with increased LCAT activity, intermediate-density lipoprotein (IDL) and free cholesterol levels of the small and very small HDL fractions decreased. We found the hemoglobin/haptoglobin complex in the hemolyzed pre-implantation sera of the patient. After one week of the implantation, the hemoglobin/haptoglobin complex almost disappeared. Immediately after the implantation, the patient's proteinuria decreased temporarily to mild levels and gradually increased to the baseline. At 48 weeks after implantation, the patient's proteinuria deteriorated with the development of mild hypertension. By the treatment with antihypertensives, the patient's blood pressure normalized. The proteinuria rapidly decreased with the normalization of blood pressure to mild proteinuria levels. The GMAC-LCAT treatment is shown to be safe in this study. It will provide novel therapeutic reagents in future medicine, including treating various inherited diseases and metabolic disorders.

802 Sustained Dystrophin Expression in an Infant with a *DMD* Exon 2 Duplication Following Dosing with scAAV9.U7-ACCA

Megan A. Waldrop[1,2], Michael W. Lawlor[3,4], Tatyana A. Vetter[1], Emma Frair[1], Margaret Beatka[3,4], Hui Meng[3,4], Megan Iammarino[1], Brenna Sabo[1], Sharmada Subramanian[1], Maryann M. Kaler[1], Tabatha R. Simmons[5], Kim McBride[6], Nicolas Wein[1], Kevin M. Flanigan[1]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Pediatrics and Neurology, Ohio State University, Columbus, OH,[3]Diverge Translational Science Laboratory, Milwaukee, WI,[4]Medical College of Wisconsin, Milwaukee, WI,[5]Nationwide Childrens Hospital, Columbus, OH,[6]Medical Genetics, University of Calgary, Calgary, AB, Canada

Duchenne muscular dystrophy is a life-limiting disorder caused by pathogenic frame-truncating variants in the *DMD* gene. Exon 2 is the most common exon duplication, and complete exclusion of exon 2 results in translational re-initiation via a downstream internal ribosome entry sequence, making it a promising target for an exon skipping therapy. We developed an AAV-mediated exon skipping vector (scAAV9.U7-ACCA) comprising four copies of a modified U7snRNA containing antisense sequences targeting the splice donor (2 copies) and splice acceptor (2 copies) of the *DMD* exon 2. We previously reported results of our open-label first-in-human study in three boys with out-of-frame exon 2 duplications. Here we report the 15-month safety and efficacy data of the youngest participant, who is the first DMD infant to receive an AAV-mediated gene therapy. Following uneventful intravenous delivery of 3.0x10^13 vg/kg at 7 months of age, he has continued to meet all developmental milestones on time and his Bayley-IV motor scores remain in the normal range at 15 months post-transfer. At 12 months post-transfer, serum creatine kinase had dropped by 91% from screening (to 1079 U/L), and muscle biopsy showed highly efficient and persistent exon skipping (in 99% of mRNA transcripts). Dystrophin protein expression was similarly robust and sustained, with immunofluorescence showing ~95% dystrophin positive fibers and western blot showing levels of 88.3% of normal (increased from 70.1% at the month 4 biopsy). We conclude that treatment with scAA9.U7-ACCA in infancy is safe and robustly efficacious with therapeutic effect sustained over at least 12 months, supporting continued clinical investigation.

803 Initial Findings of Retinal Gene Therapy in Patients with Bietti Crystalline Dystrophy

Jinyuan Wang[1], Ning Guan[2], Yang Li[1], Yuning Chen[1], Qiong Yang[1], Ying Sha[1], Hua Lv[2], Xiaojing Li[2], Hongxia Mao[2], Li Feng[2], Wei Li[3], Xiaoping Zhao[2], Wenbin Wei[1]

[1]Beijing Tongren Hospital, Capital Medical University, Beijing, China,[2]Shanghai Vitalgen BioPharma Corporation Limited, Shanghai, China,[3]Institute of Zoology, Chinese Academy of Sciences, Beijing, China

Background: Bietti crystalline dystrophy (BCD) is an incurable autosomal recessive inherited disease that leads to blindness due to mutations in the CYP4V2 gene, a gene belongs to the functional cytochrome P450 gene family (family 4, subfamily IV, polypeptide 2). Defectiveness in CYP4V2 function causes retinal pigment epithelium cell damage leading to degeneration of the retina. Thus restoration of normal CYP4V2 gene expression with adeno-associated viral (AAV) vectors can be a therapeutic strategy for BCD. We report herein the preliminary results of an ongoing exploratory study evaluating safety and efficacy of the subretinal gene replacement therapy product VGR-R01 by rAAV8 delivery of a functional CYP4V2 transgene. **Methods:** Three participants (aged 34-48 years; 1 female) with BCD resulted from biallelic mutations were sequentially assigned to one of 3 dose levels before receiving a single subretinal injection of VGR-R01 ($0.2\text{-}1.2^{10}$vg, 0.1mL per eye). Prior to VGR-R01 injection, participants received glucocorticoids for immunosuppression to decrease the risk of vector-related immune responses. Adverse events (AEs), visual function assessments including best corrected visual acuity (BCVA), multi-luminance mobility test (MLMT), static visual field testing, and full field electroretinogram, etc. were monitored throughout the study. This study is registered with ClinicalTrials.gov, number NCT05399069. **Results:** The functional vision outcome, measured by MLMT scores of the study eyes, rapidly increased by 2-points in patient 1, 1-point in patient 2, and stable in patient 3 in around two weeks upon injection of VGR-R01. Additionally, the collateral and bilateral MLMT scores changed by 0-2 points. The baseline visual acuity in all the study eyes were in the range of off-chart vision. Two weeks after administration of VGR-R01, in all patients' study eyes and collateral eyes, BCVA changed by 0-0.3 LogMAR (with the scale adapted from Holladay used to assign values for off-chart acuities). Moreover, VGR-R01 was generally well-tolerated. No serious adverse events (SAEs) or deaths were reported, and no subject experienced an adverse event (AE) that resulted in discontinuation. All these events were assessed as unrelated to VGR-R01. Retinal detachment was the most frequently reported AEs related to surgical procedure (n=2) and steroid-associated elevated white blood cell counts (n=3). Most events were mild in severity, and resolved without need for medical intervention. **Conclusion:** Subretinal gene therapy with VGR-R01 demonstrated a good safety profile and resulted in rapid improvement in functional vision in all participants with BCD. With more data being collected, we will continue to assess the effect of VGR-R01. A separate multicenter, open-label phase 1 study of VGR-R01 in patients with BCD is ongoing (NCT05694598).

804 Phase I/II Trial of MUC1*-CAR-1XX T Cells

Cynthia Bamdad[1], Joanne Mortimer[2], Yuan Yuan[2], Jennifer Specht[3], Andrew Stewart[1], Benoit Smagghe[1], Stephen Lin[2], Mark Carter[1], Tim Synold[2], Vishwas Parekh[2], Danica Walkley[1], Lihua E. Budde[2], Qing Liu-Michael[2], Kevin Yi[1], Jac-Leen Nash[1], Michael Nash[1], Jacy Marquez[1], Teresa Kim[2], Stan Hamilton[2], Stephen J. Forman[2]

[1]Minerva Biotechnologies, Waltham, MA,[2]City of Hope, Duarte, CA,[3]Fred Hutchinson Cancer Center, Seattle, WA

Background and Aim: Previous attempts to therapeutically target MUC1 failed because they targeted the tandem repeat domain of full-length MUC1, which is shed from tumor cells. More recently, CARs have incorporated antibodies, such as 5E5, that recognize trapped glycans that deposit on sites for O-linked glycosylation. However, these also target the tandem repeat domain of full-length MUC1, which alone contains sites for O-linked glycosylation. It is the transmembrane cleavage product, called MUC1* (muk 1 star), that is the growth factor receptor form of MUC1. Cleavage of MUC1 by specific, tumor-associated enzymes leads to the unfolding of the MUC1* portion, which reveals a previously hidden binding site for an onco-embryonic growth factor. The aim was to develop an antibody that recognizes this cryptic binding site, which is only revealed on cancer cells after MUC1 is cleaved to MUC1*, and incorporate it into a next generation CAR T cell. Other antibodies that bind to a linear epitope on a MUC1 cleavage product such as MUC1-C will also bind to that same linear epitope on normal, full-length MUC1. Methods: We developed a panel of monoclonal antibodies that bind to a cryptic site that is only revealed after MUC1 is cleaved to the growth factor receptor form called MUC1*. Enzymes that are known predictors of poor prognosis in solid tumor cancers cleave MUC1 to MUC1*, creating a specific conformational epitope that does not exist in full-length MUC1. Antibodies that bind to a linear epitope will also bind to full-length MUC1 so will have on-target/off-tumor toxicities. We incorporated an antibody that binds to the cryptic site on MUC1* into both a standard CAR T, huMNC2-CAR44, and a CAR-1XX, called huMNC2-CAR22. The "1XX" mutations, consist of 4 Tyrosine to Phenylalanine mutations in ITAMs 2 and 3 of CD3z, but leave the ITAM 1 intact. These mutations prevent Tyrosine phosphorylation and thus slow signaling. Results: In animals, huMNC2-CAR22 outperformed huMNC2-CAR44 on two major fronts: persistence and ability to kill low antigen expressing cancer cells while still having no effect of normal MUC1 expressing cells. We expect huMNC2-CAR22 to outperform huMNC2-CAR44 in a human trial for metastatic breast cancers, which is now open. Having said that, 7 patients have been treated to date with huMNC2-CAR44. Efficacy was measured even at low dose with best response seen at Day 28. 4 of the 7 patients had Stable Disease and 1 patient, with bone metastasis, had a Partial Metabolic Response. To date, there is no evidence of on-target/off-tumor toxicities. We expect to have patient results before ASGCT 2023. A CD19-CAR-1XX trial of 16 patients (Park et al ASH 2022 Abstract 163) reported efficacy at reduced dose, compared to the CD19-CAR-CD3z-wt, greatly increased persistence and reduced CRS incidents and severity. We expect huMNC2-CAR22, aka MUC1*-CAR-1XX, to show greater efficacy in patients because of prolonged persistence, ability to kill low MUC1* expressing cells, with increased safety due to reduction in CRS. Conclusion: Results to date of huMNC2-CAR44 Phase I/II trial validate this new target, MUC1*, for cellular therapies for the treatment of solid tumor cancers. We expect huMNC2-CAR22 to be a significant improvement over its predecessor, huMNC2-CAR44, based on its greatly increased persistence, reduced CRS in human as well as its ability to kill low antigen expressing cancer cells.

805 Biomarkers Reveal Improved Red Cell Health Following Hematopoietic Stem Cell Transplantation (HSCT) for SCD

Aliya U. Zaidi[1], Xiufeng Gao[1], Michael Tarasev[1], Robert Goodrich[1], Rasa Borhan[1], Allie Edenstrom[1], Courtney Fitzhugh[2], Patrick C. Hines[1,3,4]

[1]Functional Fluidics, Inc., Detroit, MI,[2]NHLBI/NIH, Bethesda, MD,[3]Wayne State University Division of Pediatric Critical Care Medicine, Detroit, MI,[4]Wayne Pediatrics, Detroit, MI

Introduction: Despite new therapeutic options, sustainable improvement in clinical outcomes and quality of life in sickle cell disease (SCD) remain elusive. Allogeneic hematopoietic stem cell transplant (HSCT) is the most widely available curative option for SCD. Its efficacy is assessed by frequency of pain crises, hemoglobin (Hb) response, markers of hemolysis, and level of engraftment. Normalization of red blood cell (RBC) health is a fundamental goal of successful HSCT; however, the normalization of RBC health in response to HSCT has not been clearly established. Mechanical fragility (MF) and flow adhesion of whole blood to vascular cell adhesion molecule (FA-WB-VCAM) and P-selectin (FA-WB-Psel) are standardized blood-based biomarkers developed in our lab to assess RBC membrane stability and adhesive properties respectively. The objective of this study was to determine if MF, FA-WB-VCAM, and FA-WB-Psel can monitor the normalization of RBC function in individuals with SCD post-HSCT. Methods: SCD subjects were enrolled in NIH haploidentical HSCT protocol 17-H-0069. Blood samples from 3 of 10 planned subjects were collected twice before (baseline) and 3, 6, and 12 months after HSCT. FA-WB-VCAM and FA-WB-Psel were performed at 1.0 dyne/cm^2 using a BioFlux 1000Z microfluidic well-plate system. Adherent cells were quantified and reported as cells/mm^2. MF was assessed with a proprietary system comprising an electromagnetic bead mill and fiberoptic spectrophotometry detection for non-invasive measurement of mechanically-induced RBC hemolysis. Results: Prior to HSCT, all SCD subjects experienced recurrent vaso-occlusive crises, chronic pain, and transfusion-associated iron overload. Average pre-HSCT baselines for FA-WB-VCAM and FA-WB-Psel (470±290 cells/mm^2 and 74±93 cells/mm^2, respectively; n=3) were elevated compared to the previously established high risk threshold for FA-WB-VCAM (408 cells/mm^2) and FA-WB-Psel (46 cells/mm^2). The MF index at 10 minutes (MFI10) was significantly elevated for one patient at 7.38 compared to high risk MF threshold at 7.25 in SCD; it was normal for the other two patients (5.05 and 5.85). Full donor chimerism was observed as early as 3 months post-HSCT. Progressive decrease of pain and opioid use was observed for one patient (at 6- and 12-months post-HSCT); this was not conclusive for other patients at 3 and 6 months. While LDH did not show improvement, bilirubin declined significantly (<0.5 mg/dL post-HSCT for all patients). Average RBC MF decreased 16% while

Hb increased 47% to 13.5g/dL at 12 months. At 6 months, both FA-WB-VCAM and FA-WB-Psel decreased 95% to 25 cells/mm^2 and 79% to 22 cells/mm^2, respectively (See Fig. 1). Conclusions: RBC health objectively normalized following HSCT, as reflected in FA-WB-VCAM, FA-WB-Psel, and RBC MF in the range of AA RBCs. Longer follow-up is necessary to establish clinical improvement, although the pain reduction and decrease in opioid use observed in one of the patients is encouraging. These data suggest FA-WB-VCAM, FA-WB-Psel, and MF may be objective assessment tools of the normalization of RBC health following HSCT.

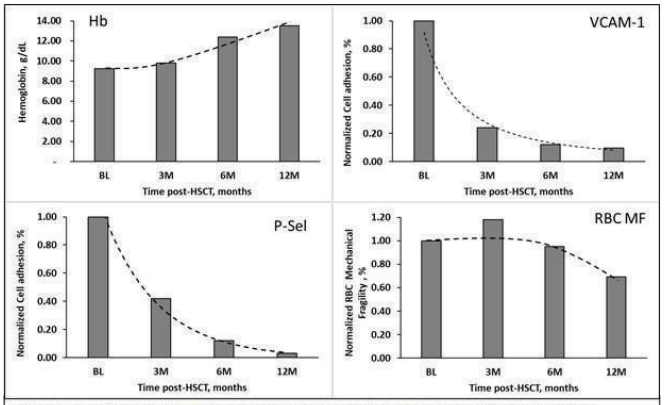


Figure 1. Average changes in Hb and metrics of blood cell function (normalized to individual baseline levels) before and after HSCT. Changes within patients were significant at p-values <0.05.

806 Preliminary Results of Follistatin 344 Episomal Plasma Gene-Therapy in Adipose Fat in Human Patients

Walter Patterson[1], Glenn Terry[2], Mac Davis[1]

[1]Minicircle Inc, Austin, TX,[2]GARM, Parrot Tree, Honduras

Follistatin 344 is a selective myostatin inhibitor which has shown promise as a target for gene-therapies to treat muscular dystrophy. In this work, an episomal plasmid based vector was developed for the expression of Follistatin 344 for extend periods of time over canonical plasmids. This Follistatin 344 expressing plasmid vector was administered to 50 patients at a dosage of 50 µg via injection into adipose fat tissue. The mechanism of transfection was DNA complexed with Linear Polyethylenimine Hydrochloride. Follistatin and Myostatin concentrations were determined via sandwich type Elisa performed on patient serum. DEXA scan was used to monitor body composition (fat, bone and lean body mass). Triglycerides, HDL, LDL and total cholesterol were monitored via lipid panels. Diabetic markers such as glucose, hemoglobin A1C, insulin and IGF were monitored for insulin sensitivity. Inflammation markers such as high-sensitivity C-reactive protein and secondary hormonal proteins such as luteinizing hormone and follicle stimulating hormone were additionally monitored in the battery of tests. Epigenetic and Glycomic analyses were performed via TruDiagnostic and GlycanAge, respectively.

807 RGX-121 Gene Therapy for the Treatment of Neuronopathic Mucopolysaccharidosis Type II (MPS II): Interim Analysis of Data from the First in Human Study

Paul Harmatz[1], Can Ficicioglu[2], Roberto Giugliani[3], Deepa Rajan[4], Joseph Hagood[5], Michele Fiscella[5], Lin Yang[6], Michelle Gilmor[5], Yoonjin Cho[5], Dawn Phillips[5], Laura Pisani[5], Paulo Falabella[5]

[1]UCSF Benioff Childrens Hospital Oakland, Oakland, CA,[2]Children's Hospital of Philadelhia, Philadelphia, PA,[3]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil,[4]University of Pittsburgh, Pittsburgh, PA,[5]REGENXBIO Inc., Rockville, MD,[6]REGENXBIO, Rockville, MD

MPS II is an x-linked lysosomal storage disease caused by deficiency of iduronate-2-sulfatase (I2S) leading to accumulation of glycosaminoglycans (GAGs) in tissues. Neuronopathic MPS II results in irreversible neurodevelopmental decline not addressed by intravenously administered enzyme replacement therapy. RGX-121, a recombinant adeno-associated virus serotype 9 capsid containing a human iduronate-2-sulfatase expression cassette (AAV9.CB7.hIDS), administered to the central nervous system (CNS) may provide a permanent source of secreted I2S, potentially correcting neurologic and systemic disease manifestations. CAMPSIITE™ is a phase I/II/III, open-label trial enrolling boys 4 months up to five years of age with neuronopathic MPS II (NCT03566043). Participants receive one image-guided RGX-121 injection to the CNS with follow-up through 104 weeks and are encouraged to enroll into a long-term, follow-up study for a total of 5 years. Assessments include safety and tolerability; measurements of CSF, plasma, and urine biomarkers; cognition, language, and motor neurodevelopmental scales; and imaging. As of August 1, 2022, 14 participants were enrolled in the phase I/II portion of CAMPSIITE in 3 dose cohorts ($1.3x10^{10}$, $6.5x10^{10}$, and $2.9x10^{11}$ genome copies/gram brain mass). RGX-121 was reported to be well-tolerated with no drug-related serious adverse events. Time of post-administration follow-up ranged from 8 weeks to 2 years. CSF GAGs, which are elevated in neuronopathic MPS II disease, showed dose-dependent reductions (with D2S6 levels approaching normal levels in cohort 3). As of December 20, 2021, interim neurodevelopmental assessments demonstrated CNS activity up to 2 years after RGX-121 administration. Additionally, there was evidence of systemic enzyme expression and biomarker activity after CNS RGX-121 administration. Updated interim results from this trial will be presented. RGX-121 has the potential to provide sustained CNS clinical outcomes and additional systemic effects in MPS II patients.

808 Optogenetic Therapy with MCO-010 for Vision Restoration in Patients with Severe Sight Loss Due to Retinitis Pigmentosa: The Phase 2b RESTORE Study

David Liao[1], Victor Gonzalez[2], Andres Emanuelli[3], Sunil Gupta[4], Charles Wykoff[5], Vitaliy Zak[2], Ananta Ayyagari[6], Subrata Bataybal[6], Sai Chavala[7], John Koester[8], Samarendra Mohanty[6], Jody Piltz-Seymour[6], Aaron Osborne[6]

[1]Retina Vitreous Associates Medical Group, Los Angeles, CA,[2]Valley Retina Institute, McAllen, TX,[3]University of Puerto Rico, San Juan, PR,[4]Retina Specialty Institute, Pensacola, FL,[5]Retina Consultants of Texas, Retina Consultants of America, Houston, TX,[6]Nanoscope Therapeutics, Dallas, TX,[7]CiRC Biosciences, Dallas, TX,[8]JMK Statistics, Goodyear, AZ

RP is a disorder caused by mutations in more than 80 different genes, resulting in progressive retinal degeneration of the photoreceptors and RPE leading to vision loss. Ophthalmic optogenetics involves the expression of transgenes encoding light sensitive proteins or opsins into the surviving retinal cells to make them directly sensitive to light. Optogenetic therapies work independently of the genetic mutation or cause of retinal degeneration and do not require RPE or photoreceptor viability, offering the potential for vision restoration even in the later stages of retinal degenerative diseases. MCO-010 is a Multi-Characteristic Opsin (MCO), delivered via an intravitreal (IVT) injection as an adeno-associated virus type 2 (AAV2) gene therapy vector with mGluR6 promoter-enhancer for ON retinal bipolar cell expression and mCherry as stabilizer-enhancer and reporter. The MCO-010 fusion protein is highly light sensitive across the entire color bandwidth of visual light with fast kinetics to minimize blur, maximizing each photon to potentially enable high-quality vision without the need for external stimulation devices.

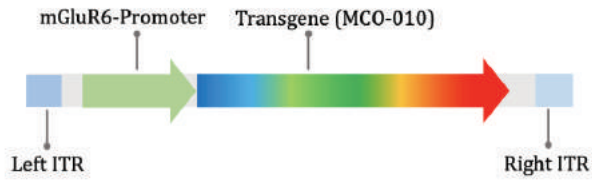

Figure 1. MCO-010 Vector Design. All 11 patients with advanced RP in a phase 1/2a open label study demonstrated improvement in vision following MCO-010 IVT injection. The therapy was well tolerated. The efficacy and safety of MCO-010 in RP patients with severe vision loss has been further assessed in the Phase 2b RESTORE study (NCT04945772). RESTORE is a 2-year, randomized, double-masked, sham-controlled multicenter clinical trial evaluating 2 dose levels of IVT MCO-010 (0.9E11 and 1.2E11 gc/eye) in advanced RP. Inclusion criteria included diagnosis of advanced RP, acuity worse than 1.9 LogMAR for study eye and presence of inner retinal cells on OCT. The primary outcome measure is change from baseline in vision-guided mobility using the Multi-Luminance Y-Mobility Test (MLYMT) at 52 weeks as assessed by central, masked graders. Other vision function tests include change in acuity and shape discrimination assessed by the low-vision multi-parameter test (LVMPT). 27 patients with advanced RP were enrolled, with the final patient randomized in February 2022. At screening, the mean age was 56 years (range 23-83), and mean study eye visual acuity was 2.2 LogMAR (range 1.95-2.25, CF/HM vision). As of February 1, 2023, 24/27 subjects had completed their week 52 study visit with no serious ocular adverse events or drug-related systemic adverse events reported. Primary efficacy and safety 52-week data for all subjects will be presented. MCO-010 is a gene agnostic optogenetic therapy designed for vision restoration in patients with severe sight loss due to outer retinal degeneration. Delivered via a single IVT injection, MCO-010 targets bipolar cells for ambient light sensitization. Efficacy and safety data from the RESTORE 2b trial will provide further evidence on the benefit/risk profile of MCO-010 including its potential to improve vision-guided mobility in patients with advanced RP.

809 Regulatory Pathway for Gene Therapy for Rare Diseases: An Illustrative Example from the PaVe-GT Platform Program

Rodica Stan[1], Richa Madan Lomash[2], Randy J. Chandler[3], Oleg Shchelochkov[3], Charles P. Venditti[4], Carsten G. Bonnemann[5], Philip J. Brooks[6], Elizabeth Ottinger[1]

[1]NIH/NCATS, Rockville, MD,[2]NCATS, Rockville, MD,[3]National Institutes of Health, Bethesda, MD,[4]NIH, Bethesda, MD,[5]NINDS/NIH, Bethesda, MD,[6]NIH / NCATS, Bethesda, MD

The Platform Vector Gene Therapy (PaVe-GT) program is an initiative started by a multi-disciplinary group of collaborators to develop adeno-associated virus (AAV) gene therapies for four rare diseases, which as a group, are relatively common but lack effective therapies. With approximately 10,000 rare diseases that affect 25 to 30 million people in the United States and less than 10% of these diseases having an approved treatment option, there is still much work to be done. Addressing the need for therapies for rare diseases under a unified platform, such as PaVe-GT, may serve as a paradigm for reducing process redundancies and increasing efficiencies in the preclinical, regulatory, and clinical activities to broadly enable the development of gene therapies for rare diseases. Here, we showcase the regulatory strategy for the PaVe-GT program's first indication. AAV9-hPCCA gene therapy is being developed to treat propionic acidemia resulting from a deficiency of propionyl-CoA carboxylase, alpha subunit (PCCA). The product's regulatory pathway has thus far progressed successfully through an **INTERACT** (or **IN**itial **T**argeted **E**ngagement for **R**egulatory **A**dvice on **C**BER Produc**T**s) meeting with the FDA and is currently in the pre-IND planning phase. In addition, this gene therapy project has also received two valuable designations: Orphan Drug (ODD) and Rare Pediatric Disease (RPDD), from the Food and Drug Administration (FDA). The ODD and RPDD programs provide sponsors with financial incentives for research and development of drugs for rare diseases. Lessons learned from our regulatory activities will be presented. In conclusion, the knowledge achieved by advancing PaVe-GT program's first product through critical regulatory milestones will be applied to the other three indications under development, with the goal of reducing process redundancies and increasing efficiencies. PaVe-GT represents a strategy for accelerating therapeutic development for rare diseases that can be disseminated to other AAV gene therapy efforts.

Thursday Poster Session

810 Deleterious Genetic Variants in the AAVR Universal Receptor (KIAA0319L) with the Potential to Limit AAV-Mediated Gene Expression

Mahboubeh R. Rostami, Jenifer M. Vasquez, Philip L. Leopold, Jason G. Mezey, Miguel de Mulder Rougvie, Ronald G. Crystal

Department of Genetic Medicine, Weill Cornell Medicine, New York, NY

Clinical studies with adenoassociated virus (AAV) mediated gene transfer demonstrate effective, persistent expression of the AAV transgene, but with significant variability to gene expression among recipients, despite identical doses. One unexplored contributor to this variability could be genetic variants in genes responsible for AAV interactions with target cells. As an initial assessment of this concept, we hypothesized that there may be genetic variation in AAVR (KIAA0319L), a 164 kb gene on chromosome 1 that codes for a type I transmembrane protein that serves as the primary receptor for many AAV serotypes. Human variants of AAVR were assessed in 3 whole genome databases: African/African-American (20,744 genomes, gnomAD), European (34,029 genomes, gnomAD), and Qatari (14,669 genomes, Qatari Genome Project database). Compared to the reference genome, the identified variants (African, European, Qatari) included: total variants (410, 508, 5713); known variants (364, 451, 3613); novel variants (46, 57, 2100); rare variants (allele frequency <0.01; 396, 502, 5194); and common variants (allele frequency ≥0.01; 14, 6, 19). The AAVR variants were classified as deleterious (loss of function) based on one of the following three criteria: (1) high impact loss of function (frameshift, stop or start lost, transcript amplification, stop gained, splice donor or acceptor variants, transcript ablation; African, European, Qatari: 5, 13, 4); (2) moderate impact loss of function (in-frame insertion or deletion, missense, protein-altering, regulatory region ablation; African, European, Qatari: 122, 154, 48); or (3) loss of function using "Combined Annotative Dependent Depletion" (CADD) and "Sorting Intolerant from Tolerant" (SIFT) analyses with the criteria of theoretical dysfunction if the CADD score was ≥20 and if the variant was classified as "intolerant" by SIFT analysis (SIFT score ≤0.05; African, European, Qatari: 51, 88, 34). The list of deleterious variants was then cross-checked with ClinVar and any variant previously described as either "benign" or "likely benign" in ClinVar was removed from the list. The final number of candidate deleterious loss of function AAVR variants were African n=45, European 79 and Qatari 20. Examples of loss of function AAVR variants included: (1) missense Lys3Thr (CADD 22.8, SIFT 0, allele frequency 0.03 in Qatari, rare in African and European); (2) missense Pro302Gln (CADD 23.1, SIFT 0.019, rare in African and Qatari); and (3) missense Ala563Val (CADD 27, SIFT 0.012, rare in European). While homozygosity of these deleterious variants likely will have a significant impact of the effectiveness of AAV gene expression, future studies will be needed to assess the impact of heterozygosity. In summary, we have identified potentially deleterious human genetic variants in AAVR, a gene coding for a critical step in gene transfer for many AAV serotypes. We suggest that this, as well as possible deleterious genetic variants in other genes coding for cellular components critical for AAV gene transfer, may play a role in variations in levels of gene expression observed in human gene therapy. Identification of these genetic variants relevant to effective gene transfer should contribute to "precision gene therapy."

811 Cas13d Multi-Targeting Efficiently Targets Sense and Antisense HRE Containing Toxic RNAs and poly-GP DPR in C9ALS Patient Cells and in C9-BAC500 Mouse Model

Daniela Martino Roth, Jeannie Chew, Hank Bradford, Takahiro Tadokoro, Akiyo Ogawa, Shawn Lee, Joshua Fong, Gustavo Villegas, Claire Geddes, Vincent Luczak, Haydee Gutierrez, Ronald Torres, Nandini Narayan, Sheik Pasha, Justin Truong, Anindita Sarkar, Greg Nachtrab, John E. Leonard, Ranjan Batra

Locanabio, San Diego, CA

Hexanucleotide repeat expansion (HRE) in the first intron of C9ORF72 gene is the most common genetic cause of amyotrophic lateral sclerosis (ALS) and frontal temporal dementia (FTD). Bidirectional transcription at the C9ORF72 repeat locus produces both sense GGGGCC (G4C2) and antisense CCCCGG (C4G2) containing toxic RNAs. Studies to date have elucidated multiple pathogenic mechanisms, including RNA gain-of-function of both sense and antisense HRE transcripts leading to formation of nuclear RNA foci and dipeptide repeat protein (DPR) aggregates generated by RAN translation. CRISPR/Cas13d is a type VI programmable nuclease with the ability to process guide-RNA arrays and target multiple RNAs for degradation. We developed a multi-targeting (MT) Cas13d construct to knockdown both sense and antisense transcripts of the C9ORF72 HRE and packaged it in a single AAV9 vector. Cas13d-MT reduced both G4C2 and C4G2 RNA Foci, sense and antisense repeat containing transcripts, and poly-GP DPR levels in C9ALS patient derived fibroblasts. Invivo studies with AAV9 packaged Cas13d-MT delivered via subpial (spinal cord) or intrastriatal injection in C9BAC-500 mice showed significant reduction of both sense and antisense HRE containing RNAs, 50-60% decrease in poly-GP DPR, and maintenance of total C9ORF72 mRNA levels. We observed sustained expression of the transgene and no signs of toxicity in-life or with histopathology at 6-8 weeks post treatment in both spinal cord and brain. Overall, our multi-targeting strategy is safe and efficacious in targeting two disease-causing RNAs simultaneously in C9ALS *in vitro* and *in vivo* models.

812 Single Dose Cocktail of AAV Vectors Coding for Peanut Allergens Prevents Peanut Allergy

Miguel Gonzalez[1], Maite Munoz[1], Roland W. Herzog[2], David M. Markusic[3]

[1]Indiana University, Indianapolis, IN,[2]IU School of Medicine, Indianapolis, IN,[3]IUSM, Fishers, IN

Introduction: Food allergy (FA) is a health problem with an increased incidence in children. FA results from an abnormal response in gut immune tolerance that leads to the activation of B cells and immunoglobulin E (IgE) class switching. Sensitization to food allergens in humans can result from different exposure routes such as the gut, respiratory tract or even the skin. The most common food allergens are

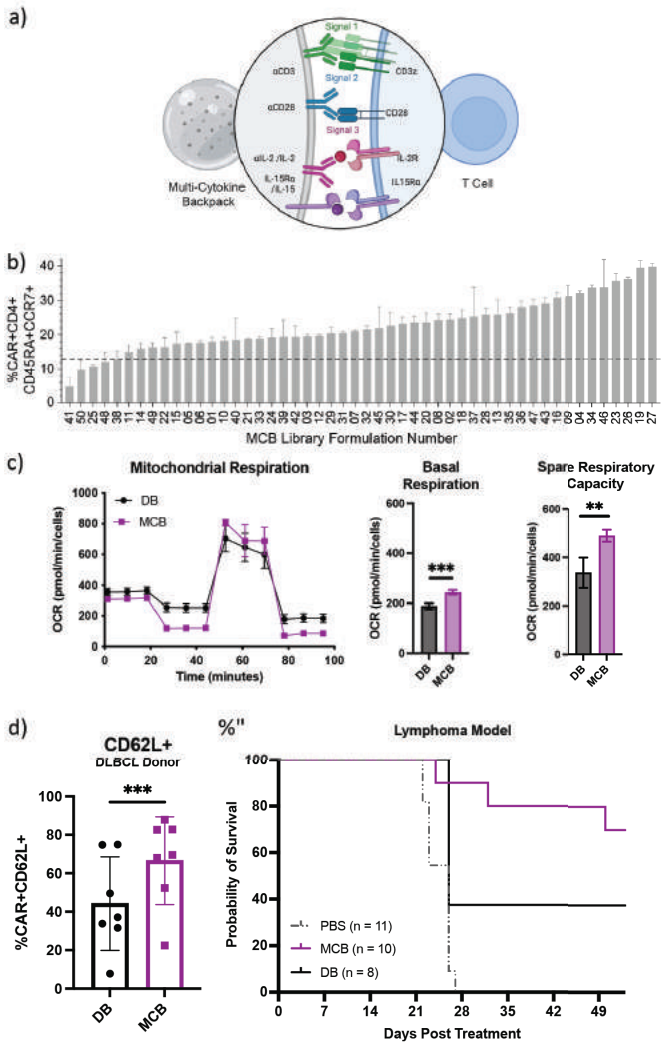
peanut (PE), milk, eggs, and tree nuts. Immunotherapies for patients with FA have shown some success in limiting allergic responses however, these approaches require lengthy protocols with repeated allergen dosing and patients can relapse following discontinuation of treatment. Following up on our previously published studies in a single allergen food allergy model, we hypothesized that we could prevent PE allergy with a single dose of adeno-associated vectors (AAV) expressing the most common PE allergens (Ara h 1, 2, 3, and 6) in the liver. Methods: 6-week-old heterozygous flaky tail ($FT^{+/-}$) female mice were injected with 10^{11} vg of a single AAV8 vector expressing Ara h 1, 2, 3, or 6, or a cocktail of all four vectors. Four weeks later, mice were bled to determine the Ara h protein expression in plasma by ELISA. Groups showing expression of Ara h proteins in plasma (animals injected with Ara h 2, 6, and AAV cocktail) and a non-AAV treated mice as control group were sensitized by epicutaneous administration (8 doses) of *Alternaria alternata* protein extract followed by PE extract. After sensitization, mice were bled, and anaphylaxis was assessed by a reduction in the core body temperature (CBT) and an increase in the symptom score (SS) scale (0: No symptoms; 1: scratching nose/head; 2: reduced activity; 3: labored respiration; 4: no activity after prodding; 5: death) measured every 15 minutes after an intraperitoneal PE injection. Finally, livers were collected to determine the Ara h protein expression and PE-specific IgE and IgG1 titers were determined in plasma by ELISA. Results: In the single AAV8-Ara h treated groups we detected Ara h 2 and 6 expression in plasma and Ara h 1, 2, 3, and 6 in the liver. A comparison between single AAV8-Ara h and AAV cocktail treated animals showed higher expression of Ara h proteins in those groups injected with a single AAV in Ara h 1 and 3 in liver (1126±56.9 vs 198.7±48.5 ng/mg of liver protein and 1.1±0.1 vs 0.6±0.1 ng/mg of liver protein for Ara h 1 and 3, respectively), Ara h 2 in plasma (44.9±6.4 vs 38.3±1.7 ng/ml), and Ara h 6 in liver and plasma (148.3±6.1 ng/mg of liver protein and 78.9±2.7 ng/ml vs 112.3±6.2 ng/mg of liver protein and 66.1±3.2 ng/ml). Nonetheless, higher expression of Ara h 2 was detected in the liver of mice receiving the AAV cocktail compared with the AAV8-Ara h 2 alone (5.7±0.7 vs 1.6±0.5 ng/mg of liver protein). After sensitization, only mice pretreated with the AAV cocktail showed a significant reduction in hypothermia (0.4°C ±0.2) and SS (0.6±0.2) compared with those treated with AAV8-Ara h 2 (-3.5°C ±1.2 and 2.7±0.2) and non-AAV group (-4.6°C ±0.31 °C and 2.7±0.3). A slight reduction in hypothermia (-2.4°C ±1) and SS (1.7±0.4) was observed in mice treated with AAV8-Ara h 6 alone compared with Ara h 2 and non-treated groups. Protection from PE allergy was associated with a reduction in PE-specific IgG1 and IgE levels. Conclusions: We demonstrated that a single dose of a cocktail containing AAV vectors coding for the liver expression of the four major PE allergens (Ara h 1, 2, 3, and 6) can protect from skin sensitization in a FA model. The reduction in the expression of the Ara h proteins in the AAV cocktail treated group suggests a role for receptor competition for hepatocyte transduction, but this does not compromise the protective effect of the therapy. Although treatment with AAV8-Ara h 6 alone showed a partial reduction of allergic symptoms, complete protection from PE allergy requires simultaneous expression of multiple PE allergens.

813 Engineering a Multi-Cytokine Backpack Platform for Manufacturing Functionally Improved CAR T Cell Products

Heather K. Lin[1], Biaggio Uricoli[2], A K M Nawshad Hossian[1], Ruby Freeman[1], Zhulin He[1], Ji Y. L. Anderson[3], Milla Neffling[3], Jonathan Legier[1], Deon B. Doxie[1], Remya Nair[1], Jean L. Koff[1], Kavita Dhodapkar[1], Mala Shanmugam[1], Erik C. Dreaden[2], Sarwish Rafiq[1]
[1]Emory University School of Medicine, Atlanta, GA,[2]Georgia Institute of Technology, Atlanta, GA,[3]908 Devices, Boston, MA

Despite the remarkable clinical efficacy of chimeric antigen receptor (CAR) T cell in diffuse large B cell lymphoma (DLBCL), only ~60% of treated patients do not benefit either due to lack of initial response or a short duration of response to therapy. Emerging research demonstrates that the initial phenotype of the CAR T cell product after manufacturing, specifically less-differentiated phenotypes, can greatly impact therapeutic outcomes. Reagents that consistently manufacture memory phenotypes within CAR T cell products could significantly improve clinical outcomes in DLBCL. We have developed a modular multi-cytokine backpack (MCB) platform which provides the signals necessary for activation, costimulation, and cytokine support during CAR T cell manufacturing in a single "all-in-one" reagent (Fig 1a). This platform affords a high degree of flexibility that allows for the assembly and screening of compositionally diverse MCB libraries to identify formulations tailored to promote specific phenotypes. For proof-of-concept of this technology, we used multi-dimensional flow cytometry to screen MCB-manufactured CD19-directed CAR T cells for the highest proportions of less-differentiated phenotypes (CD45RA+CCR7+, Fig 1b). Statistical clustering of MCB library CAR T cell phenotypes identified top candidates for further experimentation to compare to standard DynaBeads with exogenous IL-2 (DB). CAR T cells generated from DLBCL patient samples showed significantly greater proportions of less-differentiated CD62L+ cells present in MCB- compared to DB-manufactured products ($p=0.005$, Fig 1d). Evaluation of MCB-manufactured healthy donor (HD) CAR T cells by mass cytometry and subsequent FlowSOM analysis identified central memory clusters of MCB-manufactured HD CD8+ CAR T cells that significantly express more TCF1 ($p=0.014$) and CD44 ($p=0.002$). Seahorse mitochondrial stress assays revealed that antigen-stimulated MCB-manufactured CAR T cells had increased basal respiration ($p=0.0005$) and spare respiratory capacity ($p=0.004$, Fig 1c). In vivo, all formulations of MCB-manufactured CAR T cells reduce tumor burden and enhance survival benefits in lymphoma ($p<0.0001$, Fig 1e) and ovarian cancer ($p=0.008$) models. MCB-manufactured CAR T-treated mice had more hCD3+ cells in peripheral blood on day 21. Long-term surviving mice treated with MCB-manufactured CAR T cells were rechallenged on day 188 and had significantly less tumor burden ($p = 0.015$) and improved overall survival ($p=0.046$). In summary, we have engineered a powerful platform capable of screening "all-in-one" manufacturing reagents without the need for exogenous cytokine supplementation that can provide all the necessary signals to generate CAR T cell products with improved phenotypes. Through our platform, we identified MCB formulations that resulted in CAR T cell products with greater proportions of memory phenotypes, evidence of self-renewal and metabolic fitness. Importantly, MCB-

manufactured CAR T cells reduce tumor burden and enhance overall survival in both hematologic and solid malignancies, with improved in vivo persistence of functional CAR T cells.



814 *In Vivo* FiCAT Programmable Gene Writing Platform Based on Lipid Nanoparticles Delivery System

Jon Martínez de Lagos[1,2], Natalia Artigas[2], Jessica Jaraba-Wallace[2], Avencia Sánchez-Mejías[2], Marc Güell[1,2]

[1]Medicine and Life Sciences, Pompeu Fabra University, Barcelona, Spain,[2]Integra Therapeutics S.L, Barcelona, Spain

In our previous work we developed a robust gene delivery tool (FiCAT), combining the precision of Cas9 DNA scanning and targeting DNA with an engineered piggyBac transposase with donor DNA processing and transfer capacity. Here, with the aim to demonstrate FiCAT activity *in vivo*, we performed precise gene delivery to the liver using non-viral carriers that trigger less immunological responses compared to viral-based approaches. At this point, lipid nanoparticles (LNPs) have been extensively validated both pre-clinically and clinically for the delivery of different nucleic acid cargos. We first optimized both, DNA and RNA LNP formulations for *in vivo* nucleic acid delivery. With DNA-based nanoparticles, a biodistribution assessment was also performed to ensure that transgene expression was restricted in the liver. After optimizing long mRNA encapsulation and delivery with FiCAT, we precisely inserted the DNA transposon codifying our gene of interest by co-delivering FiCAT machinery to mice liver targeting Rosa26 genomic safe harbor. Precise gene writing was confirmed by direct sequencing of junction PCR in isolated livers of mice 4 weeks after LNPs systemic injection. Here, we aim to safely deliver DNA and mRNA cargos via LNPs *in vivo* thanks to our gene writing machinery (FiCAT). This precise manner of inserting entire payloads in a genome region of interest opens a window for the treatment of several genetic disorders, making an important breakthrough in gene therapy field.

815 Frequent Aneuploidy in Primary Human T Cells after CRISPR-Cas9 Cleavage

Alessio D. Nahmad[1], Eli Reuveni[2], Goldschmidt Ella[3], Madi Asaf[3], Uri Ben David[2], Adi Barzel[4,5]

[1]School of Neurobiology, Biochemistry and Biophysics, Faculty of Life Sciences, Tel Aviv University, Tel Aviv, Israel,[2]Department of Human Molecular Genetics & Biochemistry, Faculty of Medicine, Tel Aviv University, Tel-Aviv, Israel,[3]Department of Pathology, Faculty of Medicine, Tel Aviv University, Tel-Aviv, Israel,[4]School of Neurobiology, Biochemistry and Biophysics, Faculty of Life Sciences, Tel Aviv University, Tel-Aviv, Israel,[5]The Varda and Dotan Center for Advanced Therapies, Sourasky Medical Center, Tel-Aviv, Israel

Multiple clinical trials of allogeneic T cell therapy use site-specific nucleases to disrupt T cell receptor (TCR) and other genes. In this study, using single-cell RNA sequencing, we investigated genome editing outcomes in primary human T cells transfected with CRISPR-Cas9 and guide RNAs targeting genes for TCR chains and programmed cell death protein 1. Four days after transfection, we found a loss of chromosome 14, harboring the TCRα locus, in up to 9% of the cells and a chromosome 14 gain in up to 1.4% of the cells. Chromosome 7, harboring the TCRβ locus, was truncated in 9.9% of the cells. Aberrations were validated using fluorescence in situ hybridization and digital droplet PCR. Aneuploidy was associated with reduced proliferation, induced p53 activation and cell death. However, at 11 days after transfection, 0.9% of T cells still had a chromosome 14 loss. Aneuploidy and chromosomal truncations are, thus, frequent outcomes of CRISPR-Cas9 cleavage that should be monitored and minimized in clinical protocols.

816 Suppression of Neurological Deterioration in the APP1.PSEN1/APOE4 Murine Model of Alzheimer's Disease by AAV-Mediated Expression of APOE2 Christchurch

Caner Günaydin, Hailey C. Lephart, Katie M. Stiles, Neil R. Hackett, Stephen M. Kaminsky, Dolan Sondhi, Ronald G. Crystal

Department of Genetic Medicine, Weill Cornell Medicine, New York, NY

Humans homozygous for the APOE4 mutation (C112R) have a 15-fold greater risk of developing Alzheimer's disease compared to those with the APOE3 allele, while the APOE2 allele (R158C) is protective

against Alzheimer's disease. The report (Nature Med 2019; 25:1680) describing a subject homozygous for APOE3 with the Christchurch mutation (R136S) without cognitive impairment despite carrying the autosomal dominant PSEN E280A allele suggests a protective role of the APOE Christchurch mutation against Alzheimer's disease. In this study, we tested the hypothesis that AAVrh.10-mediated expression of the combined human APOE2 allele with the Christchurch mutation (AAVrh.10hAPOE2Ch), will effectively protect against the development of Alzheimer's disease in the APP.PSEN1/TRE4 amyloid plaque mouse model which has a humanized APOE4 gene, an amyloid plaque promoting presenilin mutation and a mutant amyloid precursor protein. When untreated, these mice develop the morphologic, biochemical and behavioral manifestations of Alzheimer's disease. The AAVrh.10APOE2Ch vector was administered to the hippocampus ($2x10^{10}$ genome copies) of APP.PSEN/APOE4 mice at age 2.5 months with assessment at 5.5 months. Control animals were administered PBS. The AAVrh.10hAPOE2Ch cohort had a marked increase in hippocampal human APOE protein (10.5±1.5 ng/μg compared to PBS 0.15 ± 0.03 cohort, $p<0.001$). AAVrh.10hAPOE2Ch administration reduced the levels of both soluble and insoluble amyloid peptide β42 by 77.60% and 81.90%, and soluble amyloid peptide β40 by 55.8% and 64.2%, respectively compared to the PBS cohort ($p<0.001$ all comparisons). Immunohistochemical staining of the hippocampus for β-amyloid demonstrated a decrease in the number and size of amyloid plaques following AAVrh.10hAPOE2Ch administration compared to PBS controls ($p<0.001$). Fluoro-Jade staining for neuronal degeneration in mutant mice was decreased from 40.8±3.2% in PBS mice to 21.4±2.2% in AAVrh.10hAPOE2Ch treated mice ($p<0.001$). Markers of astrogliosis and microgliosis showed a AAVrh.10hAPOE2Ch dependent decrease in GFAP and Iba1 positive cells, decreasing from 30.6±1.9% to 19.1±3.3% and 32.3±3.6% to 11.6±1.1% ($p=0.005$, $p<0.001$, respectively). Prior to sacrifice, the mice were assessed by 3 behavioral sensorimotor assays. Compared to PBS, AAVrh.10hAPOE2Ch treatment: (1) increased the number of alternations in the Y maze (9.25±1.19 compared to 5.50±0.63 in the PBS group, $p<0.001$); (2) improved the novel object discrimination index 0.20±0.09 compared to -0.17±0.06 in PBS ($p<0.007$); and (3) decreased escape latency in the Barnes maze test to 25.0±4.5 seconds compared to 89.7±2.9 seconds in the PBS cohort ($p<0.001$), all indications of improved cognition and memory in mice. In conclusion, intrahippocampal delivery of AAVrh.10 expressing human APOE2 with the Christchurch variant improves morphologic, biochemical and behavioral disease parameters in the amyloid-driven Alzheimer's mouse.

817 Our Proprietary Manufacturing Process, mAAVRx, Improves Quantity and Quality of scAAV Vectors

June Deng, Joy Wang, Kirsten Lapoint, Megan Ericson, Isabel Alberta, Shiliang Hu, Nannan Jia, Yinxing Chen, Noel Walsh, William Lee, Lauren Drouin, Gregory Preston, Jing Liao, Matthias Hebben

Alexion, AstraZeneca Rare Disease, Lexington, MA

Unlike traditional single strand AAV (ssAAV) vectors, self-complementary AAV (scAAV) vectors can produce self-complementary intramolecular dsDNA genomes without depending on the host cell DNA polymerase machinery. This can help to achieve faster, and higher levels of gene expression compared to ssAAV vectors. However, the manufacturing yields and the full-to-empty capsid ratio tend to be more challenging for scAAV than ssAAV. Previously, we reported that our proprietary manufacturing process, mAAVRx, increased vector titers and purity for ssAAV across different serotypes. Here, we describe the manufacturing and characterization of a scAAV vector to understand whether mAAVRx could improve the yield and quality of the produced scAAV vectors. We used AAV9 as the capsid serotype and SMN1 as the transgene in a case study to produce scAAV. The molar ratio for mAAVRx two-plasmid system was first optimized. Compared to the traditional three-plasmid system, mAAVRx improved the crude harvest titer by 2-fold for scAAV9-SMN1, reaching crude harvest titers between 4e11 vg/mL and 8e11 vg/mL depending on the HEK293 cell line used. We further evaluated the quality of the vectors. Vector genome analysis by alkaline gel showed one single band of the correct target genome size indicating the integrity of the packaged AAV genome. mAAVRx produced a higher percentage of full capsids compared to the traditional three-plasmid system before and after full capsid enrichment. The full capsid-percentage, measured by AEX-HPLC, was 25% with mAAVRx and 19% with the three-plasmid system. After cesium chloride ultracentrifugation purification, mAAVRx yielded 95% full capsids whereas a traditional three-plasmid system yielded 78%. In addition, the vector potency was evaluated in vivo for each production system. Wild-type mice were injected intravenously with scAAV9-SMN1 at 1E13 vg/kg. Samples from different tissue types including brain, muscle and liver were collected at multiple time points after injection and analyzed for vector copy number and mRNA expression. This result helps to further understand the in vivo potency of the vectors produced by mAAVRx. Our data supported the use of our proprietary manufacturing process, mAAVRx, for the manufacturing of ssAAV and scAAV vectors. mAAVRx showed the ability to increase vector titers and quality attributes such as genome integrity and the percentage of full capsids compared to conventional three-plasmid system.

818 Comparative Assessment of the Efficacy and Safety Associated with Delivery of scAAV-9-CB-GFP via Lumbar Puncture Route to Juvenile Cynomolgus Macaques with and without AAV9 Pre-Existing Immunity

Ghiabe Henri Guibinga[1,2], Janet Do[1,2], Bin Chu[1], Yin Gu[1,2], Rie Kikkawa[3], Fatih Ozsolak[1,2], Timothy K. MacLachlan[4]

[1]Novartis Gene Therapies, San Diego, CA,[2]Novartis Institutes for Biomedical Research, Biologics Center, San Diego, CA,[3]Preclinical Safety Novartis Institutes for BioMedical Research, East Hanover, NJ,[4]Preclinical Safety, Novartis Institutes for BioMedical Research, Cambridge, MA

Pre-existing immunity to the AAV viral capsid represents a major hurdle for AAV-based gene therapeutics. This is due partly to the fact that a substantial portion of the patient population is exposed to wild type AAVs naturally which leads them to develop antibodies against the capsid. In most clinical trials, participants must display antibody titers below a certain cut-off to be enrolled. As the prevalence of pre-existing immunity to AAV increases with age, it presents a unique challenge

for enrolling and treating patients with late/adult-onset neurological diseases. AAV-based intrathecal gene therapies administered to CSF are currently being explored in both preclinical and clinical studies. The role that the presence of pre-existing AAV antibody play in this setting is not clear. The goal of this study is to offer a comparative assessment of efficacy and toxicity markers associated with intrathecal (lumbar puncture) injection of AAV9 vectors in non-human primates (NHP) with and without preexisting immunity to AAV9. Self-complementary AAV2/9- containing a chicken beta -actin promoter driving the expression of green fluorescent protein [GFP] (scAAV9-CB-GFP) was administered via lumbar puncture to juvenile male cynomolgus macaques with and without preexisting anti-AAV9 antibody at a dose of 5 X1013 vector genome per animal and examined for a study duration of 28 days. Central nervous system (CNS) and peripheral tissues were surveyed for vector genome, mRNA, and protein biodistribution as well as for histopathology assessments. Clinical pathology and humoral immune response to the vector capsid and the transgene were also evaluated. Our data reveal that a negative or positive serology to anti-AAV9 antibody prior NHP intrathecal dosing leads to distinct peripheral organ transduction along with different enzyme activities in the liver. We also observed different expression patterns of markers in the CSF that can potentially inform safety and provide a more educated interpretation of efficacy and toxicity findings.

819 E-selectin-Overexpressing Mesenchymal Stem Cell-Based Therapy Reverses Wound Healing Impairments in Ischemic Limbs

Carlos Theodore Huerta, Yulexi Y. Ortiz, Yan Li, Antoine J. Ribieras, Francesca A. Voza, Nga Le, Zhao-Jun Liu, Omaida C. Velazquez

DeWitt Daughtry Department of Surgery, University of Miami, Miami, FL

Purpose: Unmodified mesenchymal stem cell (MSC) therapies have failed to demonstrate more than minor clinical benefits for inducing therapeutic angiogenesis and wound healing in patients with chronic limb-threatening ischemia (CLTI), and tissue loss considerably worsens the risk of extremity amputation for these patients. Here we report the effects of MSCs engineered to overexpress E-selectin, a cell-adhesion molecule capable of stimulating neovascularization, using a translational murine model recapitulating hindlimb ischemia and cutaneous tissue loss. **Methods:** MSCs were harvested from bone marrow of 8-10-week-old FVB/Rosa26Sor^{mTmG} donor mice and underwent flow cytometry to confirm Sca-1$^+$/CD29$^+$/CD44$^+$/CD73+/CD105$^+$ expression. MSCs underwent viral transduction with E-selectin-GFP/AAV or GFP/AAV. Surgical ligation of the femoral artery was performed in 12-14-week-old recipient FVB mice followed by a subsequent 4 mm cutaneous wound in the ipsilateral limb and local injection of PBS or 1x10^6 donor GFP$^+$/MSCs or E-selectin$^+$/MSCs (E-sel$^+$/MSC). Wound closure was monitored daily for 7 days, and tissue specimens were harvested. Confocal microscopy and whole-body Dil perfusion were performed to evaluate vascular density of wound tissue. **Results:** Untransduced MSCs do not express E-selectin, and E-sel$^+$/MSCs retained MSC phenotype. Mice receiving E-sel$^+$/MSC treatment (n=10) demonstrated accelerated wound closure compared to GFP$^+$/MSCs (n=10) and PBS (n=10) treated mice at each post-injury day (PID) with the greatest difference observed at PID 5 (94 ± 3% *vs.* 79 ± 10% GFP *vs.* 72 ± 9% PBS, p<0.001) and 7 (98 ± 2% *vs.* 86 ± 8% GFP *vs.* 87 ± 6% PBS; p<0.010). Collagen deposition was more abundant in wounds receiving E-sel$^+$/MSCs (21 ± 4% *vs.* 5 ± 1% GFP *vs.* 9 ± 1% PBS). DiI perfusion at PID 10 demonstrated increased vessel density in wounds treated with E-sel$^+$/MSCs (76 ± 15% *vs.* 29 ± 7% GFP *vs.* 9 ± 5% PBS relative vascular density). E-sel$^+$/MSCs exhibited improved viability with more mTmG$^+$-E-sel$^+$/MSCs (13 ± 3 cells/high powered field (HPF) *vs.* GFP$^+$/MSCs 3 ± 2 cells/HPF *vs.* PBS 0 ± 0 cells/HPF, p<0.010) at PID 7 by immunofluorescent microscopy. **Conclusion:** E-selectin-overexpressing MSCs overcome impairments associated with wound healing in ischemic limbs. These data exhibit the potential role for E-selectin-modified MSCs as a novel cell therapy in future clinical applications for delayed and non-healing wounds in patients with CLTI.

820 Targeting a NIS-Expressing Oncolytic Adenovirus to Colorectal Cancer

McKenzie White, Stacey Wilber, Sacha Robert, Kazuho Inoko, Margarita V. Romanenko, Eric Jensen, Subree Subramanian, Clifford Steer, Julia Davydova, Christopher J. LaRocca

University of Minnesota, Minneapolis, MN

Introduction: Many patients with colorectal cancer will ultimately develop advanced or metastatic disease at some point during their disease course. Unfortunately for some of these individuals, surgical resection and systemic chemotherapy may not effectively treat the cancer. Novel treatments are desperately needed for these individuals and oncolytic adenoviruses (OAd) represent one such innovative treatment approach. Methods: Our group has designed an oncolytic adenovirus backbone structure which utilizes a ΔE3 structure and expresses the sodium iodide symporter (NIS) with each cycle of viral replication (OAd-NIS). Optimal fiber structure, cytocidal effects, and transgene expression were evaluated *in vitro* in multiple human colorectal cancer cell lines. Furthermore, PET/CT imaging was used to demonstrate the ability of the virus to facilitate imaging and radiotracer (^{124}I) uptake in colorectal tumors in an *in vivo* murine model. Results: Previously, our group has reported the use of a NIS-expressing oncolytic adenovirus to facilitate NIS expression and radionuclide uptake in pancreatic cancer and lung cancer models. Here, we utilize the ΔE3 NIS backbone structure and optimize the vector to target colorectal cancer. Multiple adenovirus fibers (Ad5 Wt, Ad 5/3, RGD) were tested *in vitro* to determine which would yield optimal OAd binding, transduction, and replication. In all cell lines tested, the Ad 5/3 fiber was superior. In crystal violet assays, the OAd-NIS virus demonstrated strong cell-killing effects across multiple human colorectal cancer cell lines. Notably, this robust cytocidal effect was present in the OAd-NIS virus which incorporated the Cox2 tissue specific promoter. Following anti-human NIS antibody staining *in vitro*, there was evidence of strong NIS expression in all tested cell lines. Human colorectal cancer xenografts were established in the flanks of nude mice and subsequently treated with the OAd-NIS virus. After ^{124}I administration (via peritoneal injection), the Sophia G8 system was used to acquire PET/CT images. Flank tumors demonstrated strong signal which highlights the ability of the OAd-NIS virus to facilitate NIS expression in the tumors allowing for radionuclide-based imaging for colorectal cancer. Conclusion: The binding and transduction of our OAd-NIS virus in colorectal cancer can be optimized with the use of a chimeric Ad 5/3 fiber. The vector

demonstrates robust cytocidal effects and NIS expression *in vitro* across multiple colorectal cancer cell lines. Strong NIS-transgene expression enables PET/CT imaging with radioactive iodine. Future studies will utilize patient-derived tissues to further evaluate the OAd-NIS in *ex vivo* and *in vivo* models. Additionally, radioiodine ^{131}I will be used in combination with OAd-NIS in murine models to evaluate the oncolytic effects of the combination regimen.

821 Potential Treatment for CMT2S Caused by IGHMBP2 Cryptic Splice Variant with ASO Based Therapeutic

Sandra Paulina Smieszek
Vanda Pharmaceuticals, DC, DC

Charcot-Marie-Tooth disease Type 2S (CMT2S) (OMIM 616155), is a rare autosomal recessive type of CMT, an inherited peripheral neuropathy. Rare variants in immunoglobulin mu-binding protein 2 (IGHMBP2) have been shown to cause CMT Type II. Specifically, they have been shown to result in abnormal RNA processing which likely leads to alpha-motor neuron degeneration. CMT2S is primarily characterized by distal muscle atrophy, weakness with areflexia, and relatively minor sensory involvement. A patient was reported with a suspected diagnosis of CMT. Further evaluations on this patient has confirmed existence of consequential variants within IGHMBP2. Whole genome sequencing has revealed a paternally inherited cryptic splice site variant (inherited non-coding variant (c.1235 + 894 C>A) deep in intron 8). RT-PCR analysis was consistent with activation of the cryptic splice site. Bidirectional sequencing of cDNA derived from the patient's cells identified both ends of the splicing alteration. The abnormal transcript was shown to undergo nonsense-mediated decay (NMD), resulting in haploinsufficiency. The objective of this study was to target IGHMBP2, specifically the cryptic splice site variant, with a novel antisense oligonucleotide (ASO) designed to avoid nonsense-mediated decay and haploinsufficiency. We have obtained the patient's fibroblast cell line and confirmed the variant with whole genome sequencing (WGS). Furthermore, we also confirmed existence of NMD induced by cryptic splicing. We designed an ASO targeting specifically deep in intron 8 (c.1235 + 894 C>A). The ASO was an 19mer targeting the sequence around CACTTCCAC(A)GGGGGAAGA. Analysis of the area of interest led to the design of several ASOs. These were further screened and prioritized based on optimal in silico binding affinity. The designed ASOs were chemically modified by adding a phosphorothioate backbone MOE. CMT Type II patient-derived fibroblast cells underwent ASO treatment (10uM) and incubation for 48h. Successful cellular entry of the ASO was additionally confirmed with flow cytometry and fluorescin labelled ASO (GFP+ 99.8%). Upon treatment with ASO, we have observed a significant increase (~30% increase) of the IGHMBP2 protein levels in the oligo treated samples as compared to control (untreated samples) (WB antibody Sigma SAB2106426). Additionally, qPCR results confirmed increased ratio of restored WT transcript to cryptic exon-containing transcript (~1.3-fold). Furthermore, the ASO has shown to have limited off-target effects in silico. While the improved clinical formulation of the tested ASO may be necessary, the current preclinical data are supportive of being a potential treatment restoring the IGHMBP2 protein levels. An increased number of cases of autosomal recessive Charcot-Marie-Tooth disease Type 2S caused by IGHMBP2 consequential variants are being reported. The N-of-1 precision medicine approach may prove instrumental to the design of treatments for this highly diverse genetic disorder. This case exemplifies the shifting boundary between rapid WGS-based clinical diagnoses available and research capabilities allowing for the design of personalized ASO-based treatments.

822 Integration of a Microfluidic Mechanoporation Device in the Gene-Edited CAR-T Cell Production Workflow

Tong Yu[1], Navdeep Jhita[2], Sunil S. Raikar[2], Todd Sulchek[1]
[1]Georgia Institute of Technology, Atlanta, GA,[2]Emory University, Atlanta, GA

Introduction: Adaptive cell therapies, including Chimeric Antigen Receptor-modified (CAR) T cell therapy and T Cell Receptor-modified (TCR) T cell therapy, have the potential to provide a curative medicine to oncological diseases, due to their ability to form memory populations that persist for decades. Successful translation of them is enabled by gene editing technologies that provide targeted cytotoxicity to immune cells through the delivery and expression of synthetic receptors required to target tumor antigen and destroy tumor cells. In addition, gene editing can be applied to introduce new functions or disable negative regulators of immune cell killing to generate more potent cell products. As the field of gene engineering progresses, developing of scalable and affordable gene delivery technologies is also required. The current cell therapy products rely on viral vectors to internalize transgenes. The process is costly and labor-intensive, display heterogeneity in their quality attributes, and pose a risk of insertional mutagenesis. Electroporation is a conventional non-viral method to deliver gene modifying cargo has been used in manufacturing of gene edited T cells. Electroporation demonstrated 15-45% gene disruption rate in cGMP manufacturing. However, high delivery efficiency can be accompanied by cell loss, delayed expansion, genetic lesion, and aberrant cellular physiology, which may pose a risk to product safety and functionality. As an alternative, we have developed a microfluidic mechanoporation device capable of delivering large biomolecules (>2,000 KD) to a variety of cell type via volume exchange between the cytosol and surrounding media, which is induced by repeated and rapid compression of cells. This volume exchange for cell transfection (VECT) device achieved superior cell viability and proliferation without sacrificing the delivery efficiency. In this study, we aim to test compatibility of VECT device integrated in a CD5-knockout CAR-T cell manufacturing workflow. Result: We first evaluated the cell biomechanical responses of unactivated and 1 activated primary T cells. T cells were found to expand in size and grow softer over 3-days of activation. We next optimized microfluidic channel designs for processing T cells by considering a number of device parameters. Under tested conditions, we could show >90% delivery of 500KD dextran to non-activated and 1-day activated T cells with over 80% viability. We then demonstrated effective production of CD5-knockout CAR T cells using a combined microfluidics and viral transduction approach. We performed CRISPR-based knockout of the CD5 locus in 1-day activated T cells and achieved 65% knockout. Edited T cells were transduced with a CD19 CAR in a 20hr coincubation with a lentiviral vector. After 10-day expansion, processed cells result in a 4-fold increase in gene edited CD5-knockout CAR T cells compared to a workflow using electroporation. We

found that rapid compressions in VECT devices did not impair the transduction efficiency (35% in VECT processed and 28% in control population). Processed T cells also show similar composition in stem memory T cells. In a killing assay against CD19+ cancer cells, VECT treated T cells show similar cytotoxicity as the CD19 CAR control cells, indicating VECT does not negatively impact CAR-T cell potency. Conclusion: The VECT microfluidic device can be applied to T cells in various stages of activation, expanding its usefulness to both traditional and rapid manufacturing workflows. Cell mechanics can be used to guide device optimization. The VECT process did not reduce cell proliferation, transduction efficiency, or cytotoxicity. The observation that VECT processed T cells had higher transduction efficiency is interesting to consider as an approach to improve transduction efficiency and reduce vector consumption in next-gen manufuctuing.

823 AAV9-Mediated Overexpression of MBNL Rescues Cardiac Phenotypes in the Microsatellite Expansion Disorder Myotonic Dystrophy Type 1

Rong-Chi Hu, Thomas A. Cooper
Baylor College of Medicine, Houston, TX

Myotonic dystrophy type 1 (DM1) is a multisystemic, autosomal dominant disease caused by a CTG expansion in the 3' untranslated region of the *DMPK* gene. Over half of individuals affected by DM1 have cardiac involvement, such as conduction defects and arrhythmias, which can lead to sudden cardiac death, the second leading cause of death in DM1. RNA containing expanded CUG repeats (CUGexp) transcribed from the expanded *DMPK* allele causes DM1 pathogenesis by disrupting functions of RNA binding proteins, which regulate alternative splicing (AS) transitions during postnatal heart development. For example, muscleblind-like (MBNL) protein family, is sequestered on the CUG_{exp} RNA, resulting in a loss of function. Thereby, misregulation of AS leads to the expression of protein isoforms that are incompatible with adult tissue function, which cause disease features. While many molecular effects of CUG_{exp} RNA have been identified in skeletal muscle, the details of how CUG_{exp} RNA induces cardiac involvement are unknown. We used our DM1 heart mouse model (CUG960), which expresses cardiomyocyte-specific and tetracycline-inducible RNA containing 960 interrupted CUG repeats (CUG960), to determine mechanisms of cardiac pathogenesis by testing for phenotypic rescue. The induced CUG960 mice not only show nuclear RNA foci with MBNL colocalization and splicing defects, but also develop conduction delays and arrhythmia characteristic of DM1 that is reversible upon loss of CUG960 RNA expression. Systemic AAV9 was used for heart-specific overexpression of epitope-tagged MBNL1 and/or MBNL2 that was confirmed in left ventricles and atria of induced CUG960 mice. AAV9-MBNL1, -MBNL2, and MBNL1+2, but not the AAV9-tdTomato control, significantly reduced the disrupted AS events, as well as the prolonged QRS and QTc conduction intervals induced by CUG_{960} RNA. All three cohorts showed rescued heart weight and echo parameters, such as ventricular wall thickness and ejection fraction. Interestingly, AAV9-MBNL1 showed a greater effect in QTc intervals and trends of having better rescue levels in multiple molecular and physiological phenotypes compared to AAV9-MBNL2. Moreover, rescue levels of AAV9-MBNL1 alone were similar to dual expression of AAV9-MBNL1+2. Overall, the data indicate that MBNL1 and MBNL2 both play a crucial role in DM1 cardiac pathogenesis, while MBNL1 may have a greater influence.

824 Characterizing Prototype Fixed Cell-Based Reference Materials for Genomic and Flow Cytometry Measurements

Mahir Mohiuddin, Alessandro Tona, John T. Elliott
NIST: National Institute of Standards and Technology, Gaithersburg, MD

Lentiviral vectors as a conduit for genetic engineering have emerged as a powerful technology in the field of cell and gene therapies to treat a wide array of diseases including various cancers, autoimmune disorders, and hereditary diseases. As gene and cell therapies are developed, a major limitation is identifying the number of gene insertion replicates due to the indiscriminate lentiviral vector-based genome editing process. Hence, we aim to address that limitation by providing a reference material with known vector insertion copies that has been tested for stability and homogeneity during in-house development and interlaboratory transfer of the materials. Using Jurkat cells with defined vector copy numbers (VCN 0, 1, 2, 3, 4) of GFP-tagged lentiviral vector inserted into the host genome (Paugh et. al., Scientific Reports, 2021), we generated fixed prototype cell-based reference materials to preserve and analyze specific features of the cell, such as nuclear material, fluorescent proteins, surface antigens, and optical scattering properties. We used a mixture of organic solvents to preserve genomic material and present a corresponding validation assay to monitor the stability and interlaboratory transfer of the fixed cells with commonly used viability (DAPI staining) and DNA (qPCR) measurement platforms. Next, MBS crosslinker, in conjunction with microtubule stabilizing buffer, was employed to retain cytosolic fluorescent proteins, cell surface markers, and scattering properties in fixed cells that can serve as a reference for flow cytometry and image-based analysis. Importantly, we show that the fixed prototype reference materials can be fixed in large batches in-house to ensure reproducibility and subsequently distributed between laboratories to allow horizontal comparison of datasets. Taken together, these fixed VCN cells exemplify a high quality, stable, and homogenous reference material that can be applied to assay development and bioprocess validation for gene and cell therapies.

825 Iodine-125 Seeds Implantation Combined with PD-1 Inhibitor Plus Platinum-Based Chemotherapy for Advanced Non-Small Cell Lung Cancer: A Retrospective Study

Jingyi Wang[1], Lan Sun[1], Yuanyuan Zhang[2], Xiaoqing Li[1], Dan Qiu[1]
[1]Bishan Hospital of Chongqing Medical University, Chongqing, China,[2]Jiulongpo District People's Hospital of Chongqing, Chongqing, China

Purpose: To evaluate the efficacy and safety of iodine-125 seeds implantation combined with PD-1 inhibitor plus platinum-based chemotherapy for patients with advanced non-small-cell lung cancer (NSCLC). Methods: A total of 21 advanced NSCLC patients were retrospectively analyzed from September 2019 to June 2022, who had undergone iodine-125 seeds implantation combined with

PD-1 inhibitor plus platinum-based chemotherapy. The response of treatment was evaluated according to the evaluation standard for solid tumor efficacy version 1.1, and treatment-related toxicities were evaluated according to NCI-CTCAE version 5.0. The median follow-up time, progression-free survival (PFS) and overall survival (OS) time were calculated by Kaplan Meier method. Log-rank test was used for comparison of survival curves between and among subgroups. The association of dose with response to treatment was analyzed by Pearson's correlation. $p<0.05$ was considered statistically significant. Results: The median follow-up time of these patients was 11.2 months (range: 3.4-23.5 months). The median PFS and OS were 11.2 months (95%CI: 7.4-14.9 months) and 14.3 months (95%CI: 11.0-17.5 months), respectively. Of the 21 patients, 3 (14.3%) experienced a complete response, 5 (23.8%) experienced a partial response, and 13(61.9%) had stable disease. The objective response rate (ORR) was 38.1%, and the disease control rate (DCR) was 100.0%. The most common treatment-related toxicities were radiation pneumonitis (grade 2, 9.5%) and hypothyroidism (grade 1, 9.5%). Treatment-related toxicities of grade 3 or higher were not found. Conclusions: Iodine-125 seeds implantation combined with PD-1 inhibitor plus platinum-based chemotherapy is safe and tolerable, improving the survival of these advanced NSCLC patients. Keywords: NSCLC, Immunotherapy, PD-1, I-125 seeds implantation

826 Genomic Characterization of AAV Products Using Multiplex ddPCR and Nanopore Sequencing

Bisma Ajaz[1], Peter Webster[2], Brian Collins[2], Isabella Pajevic[1]

[1]Solid Biosciences, Charlestown, MA,[2]Solid Biosciences, Cambridge, MA

Understanding the identity and integrity of AAV gene therapy products is an essential part in their characterization. Both identity and integrity have the potential to impact therapeutic effect if fragmentation occurs. Understanding this aspect of gene therapy can provide insight into whether the product is intact, fragmented, or potentially being mispackaged. Many approaches to evaluate integrity are available but often introduce bias or provide incomplete information. These methods may be less accurate, provide less information, or misrepresent packaged DNA. Ideally, genomic characterization should include methods to address the 1) ID of the GOI of interest (2) characterization of the amount of full-length gene of interest (GOI) packaged (3) quantification and identification of the mispackaged DNA (4) characterization of the length of DNA (GOI and contaminating) packaged in the AAV vector (5) relationship between GOI and mispackaged DNA. Multiplex digital droplet PCR (ddPCR) has been developed as an effective analytical method to determine the integrity of the product. By measuring the % of connected region for the gene of interest (GOI) with primer sets on opposite ends of the GOI, the percent of intact product can be determined robustly and accurately following DNA amplification. If the two targets on opposite ends of the GOI are positive, then the genome can be considered intact. While Multiplex ddPCR has proven consistent results for % of the full length gene packaged, it does not provide much information on the product identity. Next Gen sequencing, such as Nanopore Sequencing can provide valuable insight into the identity of gene product and other packaged DNA. With Nanopore sequencing, long read sequencing is achieved by reading the packaged DNA strand and aligning it to theoretical reference sequences provided. As the Nanopore sequencing method has the potential to introduce bias, this abstract describes the use of two methods and the value of each approach: Tagmentation Method and the guide RNA Method. In the Tagmentation method, the DNA product is fragmented so adaptors can attach to read the bases. With the guide RNA, DNA sequence is targeted at the ITRS so that a full reading is achieved. As the guide RNA method does not compromise genome integrity through fragmentation, sequencing results show a fragment size distribution that can be used as a comparison to % intact results obtained by Multiplex ddPCR. To obtain information on identity of the product, however the Tagmentation method provides better insight on DNA species identity and information on mispackaging. The combined use of genetic characterization approaches such as multiplex ddPCR, the Next Gen sequencing allows for a more robust and accurate characterization of the packaged DNA length, integrity and identity.

827 CRISPR RNA Targeting Tool Comparison for *UBE3A* Unsilencing in Angelman Syndrome

Ulrika Beitnere[1], Tomas Salter-Cid[1], Miranda S. Garcia[1], Henriette O'Geen[1], David Colognori[2], Madison Drea Hypes[1], He E. Yang[1], Timothy A. Fenton[3], Harry M. Chen[1], Benjamin D. Brophy[1], Casiana E. Gonzalez[4], Paula A. Vij[4], Kyle D. Fink[4,5], Jill L. Silverman[3,5], Jennifer A. Doudna[2,6,7], David J. Segal[1,5,8]

[1]UC Davis Genome Center, Davis, CA,[2]Innovative Genomics Institute, UC Berkeley, Berkeley, CA,[3]Department of Psychiatry and Behavioral Sciences, UC Davis, Sacramento, CA,[4]Neurology Department, Stem Cell Program and Gene Therapy Center, UC Davis, Sacramento, CA,[5]UC Davis MIND Institute, Sacramento, CA,[6]Department of Molecular and Cell Biology, UC Berkeley, Berkeley, CA,[7]California Institute for Quantitative Biosciences (QB3), University of California, Berkeley, Berkeley, CA,[8]Department of Biochemistry and Molecular Medicine, UC Davis, Davis, CA

Angelman Syndrome (AS) is a rare neurodevelopmental disorder that arises from a dysfunctional or missing maternal *UBE3A* expression in the brain, causing severe intellectual and motor disability. There is currently no cure or effective therapeutic for AS patients. Due to a brain-specific long non-coding RNA transcript known as the UBE3A-antisense (*UBE3A-ATS*), paternal *UBE3A* remains silenced. It is,

therefore, possible to restore brain *UBE3A* expression by reactivating the paternal allele. Recent studies have shown that CRISPR-Cas13 systems can efficiently degrade RNA in many organisms, including mammalian cells (Konermann et al, 2018), and could even be used for CNS disorders (Powell et al., 2022, Morelli et al., 2023). However, more recent studies have detected significant collateral damage of bystander RNA (Tong et al, 2022; Ai et al. 2022). Here, we present for the first time that the recently characterized CRISPR-Csm complex, a multi-protein effector from type III CRISPR systems in prokaryotes (Colognori et al. 2023), provides an even better RNA ablation of *UBE3A-ATS* than Cas13d for Angelman Syndrome. Additionally, we compare it to a new high-fidelity Cas13d (hfCas13d) that was published recently (Tong et al. 2022). To compare the different tools, we used a HEK293T screening system. Plasmids were delivered to the cells to produce the target RNA, consisting of a region of the UBE3A-ATS fused to a green fluorescent protein (GFP). Guides were expressed from plasmids containing the red fluorescent protein mCherry or a blue fluorescent protein BFP, thus giving insight into the delivery of the different RNA targeting tools and collateral damage. Furthermore, we compared the Cas13d and Csm on AS patient iPSC-derived neurons and AS rat primary neurons using lentivirus and the same guides. We delivered the best candidates of hfCas13 and Csm guides to the brain of the AS rat model using an adeno-associated virus (AAV) to measure the *Ube3a and Ube3a-ATS* expression. This study provides the basis for an RNA-targeting CRISPR therapy for the treatment of Angelman Syndrome.

828 TruStable™: A Fully Integrated Inducible Stable Producer Cell Line for AAV Manufacturing

Sandhya Pande, Blake Engelbert, Chris Abeles, Ramsey Saleem, Ken Prentice

Shape Therapeutics Inc., Seattle, WA

Adeno-associated viruses (AAV) are vectors of choice for many gene therapy products. Despite the undeniable suitability of AAV vectors for gene transfer, challenges remain to effectively manufacture these critical medicines for commercial and large patient population applications. Transient transfection is the most common method for the production of recombinant AAV vectors (rAAV). Though versatile, transient transfection suffers from limited scale up potential, as well as supply chain challenges in procurement of GMP grade plasmids. Other approaches involve integration of rAAV transgenes into producer cell lines and a final transduction step with helper viruses to trigger rAAV production. These transduction-based approaches require GMP manufacturing of complex helper viruses and subsequent clearance of these viruses from the final rAAV vector preparation prior to patient dosing. We have therefore developed TruStable, a HEK293-based serum free, suspension adapted cell line that has all components required for rAAV production stably integrated in its genome in order to simplify rAAV production at any manufacturing scale. Core to this system is an inducible, recombination-based molecular production circuit that silences cytotoxic viral elements during initial stages of cell expansion and allows for a simple "on" switch for viral production once an optimum cell culture environment is achieved. Our system uses a two-trigger small molecule switch to turn on rAAV production, providing complete repression of toxic viral elements in the "off" state. In the "on" state, the use of native AAV promoters for replicase and capsid expression ensures a controlled ratio of these viral components for optimum rAAV production. First, a plasmid encoding inducible adenovirus helper genes plus recombinase is stably integrated into the genome of suspension HEK293 cells. This helper cell line is then used as a host cell line to simultaneously integrate recombinase-inducible serotype specific, replicase-capsid plasmid and AAV ITR flanked transgene plasmid to create program specific polyclonal production pools. Single cell cloning of the production pools using an automated single cell isolation system and a high throughput plate based production assay allows us to select monoclonal cell lines that yield high titers with desired critical quality attributes. We have generated several TruStable cell lines that produce self-complementary rAAV vectors expressing a variety of transgenes. These cell lines readily scale into bioreactors and produce consistent titers for at least fifty population doublings demonstrating the scalability and robustness of the system. The combination of molecular production circuits and the ability to select specific clones based on productivity and product quality attributes provides substantial improvement over other rAAV production methodologies. The TruStable producer cell line can be used to package a variety of payloads within a capsid serotype of choice. High titer clones can be obtained in a few weeks to support small to large scale manufacturing runs.

829 AAVone: An All-in-One Plasmid System for Efficient AAV Production

Qizhao Wang, Yu Liu, Cuiping Chen, Rongze Yang, Lijian Fan, Bing Wang, Lemin Wang, Yuyan Wang, Zhen Shi, Cheng Xu, Daozhan Yu

AAVnerGene Inc, Rockville, MD

Recombinant adeno-associated viral (AAV) vector production is seen as complex, with the production scale-up regarded as a major challenge technically, and a large barrier for commercialization. Currently, transient transfection of plasmid into mammalian cells (such as HEK 293) is the strategy most commonly used in clinical grade manufacturing of AAV vectors. Typically, three plasmids are used: one carrying the AAV regulatory (Rep) and structural capsid (Cap) genes, one carrying the ITRs and transgene, and one carrying the specific genes that provide adenoviral helper functions. The transfection approach is fairly rapid and versatile and has been used to produce different serotypes of AAV vectors. However, producing GMP grade of AAV with high consistency, high purity and free of process-related impurities and variants remains a challenge. Production of three plasmids is time-consuming and labor-intensive. To solve those problems, we developed an all-in-one AAV production system, called AAVone (Fig.1). Firstly, we created a mini-pHelper with size down to 8.4 kb by deletion the introns of E2 and E4 expression cassettes. Second, we integrated either AAV helper genes (Rep and Cap) or AAV vector genome into the mini-pHelper and created two version of dual-plasmid systems. Third, we integrated all the necessary elements into one plasmid. Thus, in the AAVone system, Ad helper genes (E2A, E4orf6/7 and VA RNA), AAV helper genes (Rep and Cap), and AAV vector genome are assembled into one plasmid and AAV vectors are simply generated by transfection one plasmid into host cells. The AAVone plasmid has total size of 13.9~17.9kb, depending on the size of AAV vectors. Using AAV2-CMV-EGFP as example, AAVone system achieved unpurified yields of $0.5\sim1.5\times10^{15}$ viral genomes (VG)/L cell culture and average purified yields of $>2\times10^{14}$ VG/L, which is 1.5~3 fold higher than triple-plasmid system. Moreover, AAVone system has low batch variations, as it only needs one plasmid successfully to be transfected into a cell, without the need to co-transfection of the other two plasmids (Fig.2). AAV vectors generated by AAVone and traditional triple-plasmid system has similar infectivity, empty/full ratio, Rep and Cap genomic contaminations, but lower level of rcAAV, AmpR or KanR genomes in both adherent and suspension HEK 293 cells. Moreover, AAVone system uses less plasmid amount, and avoids the ratio optimization steps comparing with the triple-plasmid system. Taken together, AAVone is a simple, economic, but high consistency and high efficiency AAV production system, especially for GMP grade AAV production.

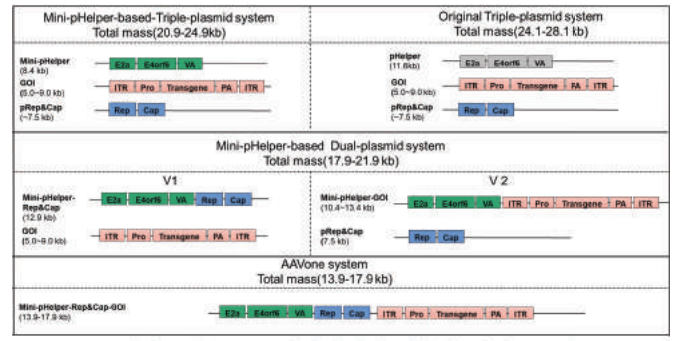

Fig.1 A composite of schematics showing mini-pHelper based triple-plasmid, dual-plasmid and AAVone production system.

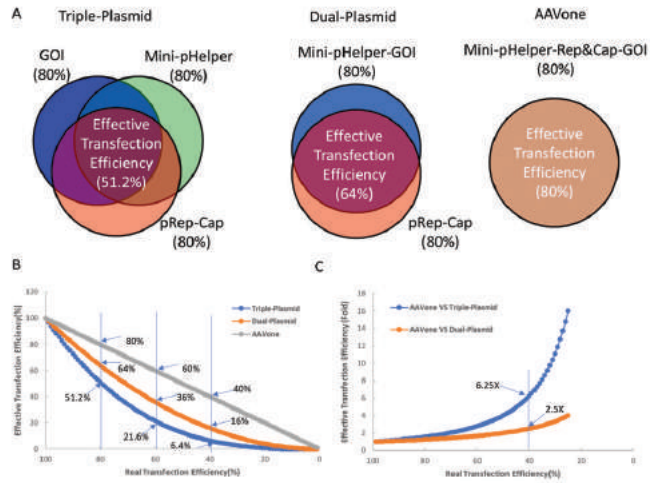

Fig.2 A composite of schematics showing the package efficiency of AAVone system in comparison to triple-plasmid system and dual-plasmid system. AAV package efficiency is depending on the effective transfection efficiency. For the triple-plasmid system, only all three plasmids are successfully transfected into a cell, the cell can produce AAV vector. Thus, the effective transfection efficiency is cube of real transfection efficiency of each plasmid. For the dual-plasmid system, the real transfection efficiency is square of real transfection efficiency. For the AAVone system, the effective transfection efficiency is equal to the real transfection efficiency. For example, if one batch have 80% of real transfection efficiency, the AAV packaging effective transfection efficiency for triple-plasmid, dual-plasmid and AAVone are 51.4%, 64% and 80%, respectively(A). AAV package efficiency would dramatically decrease when the batch has low real transfection efficiency in triple-plasmid system, but only slight decrease in AAVone system (B). At 40% real transfection condition, the effective transfection efficiency of AAVone system is 6.25 times of triple-plasmid system(C). Taken together, AAVone is a high consistency and high efficiency AAV production system.

830 *In Vivo* Gene Transfer of Doggybone DNA Carrying High-Expressing Factor IX Expression Cassettes

Yuanyi Xu[1], Meng-Ni Fan[1], Ting-Yen Chao[1], Claire Kerridge[2], Attaybenes Socas[3], Helen Horton[3], Sarah Moore-Smith[3], Carol H. Miao[1,4]

[1]Seattle Children's Research Institute, Seattle, WA,[2]MHRA, London, United Kingdom,[3]Touchlight Genetics Ltd, Hampton, United Kingdom,[4]Department of Pediatrics, University of Washington, Seattle, WA

Doggybone™ DNA (dbDNA™) is a linear, double stranded, and covalently closed synthetic DNA construct. It eliminates the bacterial sequence and shows high expression profile. We explored the potential of adopting dbDNA in nonviral gene transfer of human factor IX (hFIX) for treatment of hemophilia B. The dbDNA and plasmid vector containing a high-expressing hFIX cassette driven by a hepatic control region (HCR) and hepatocyte specific human α-1 antitrypsin

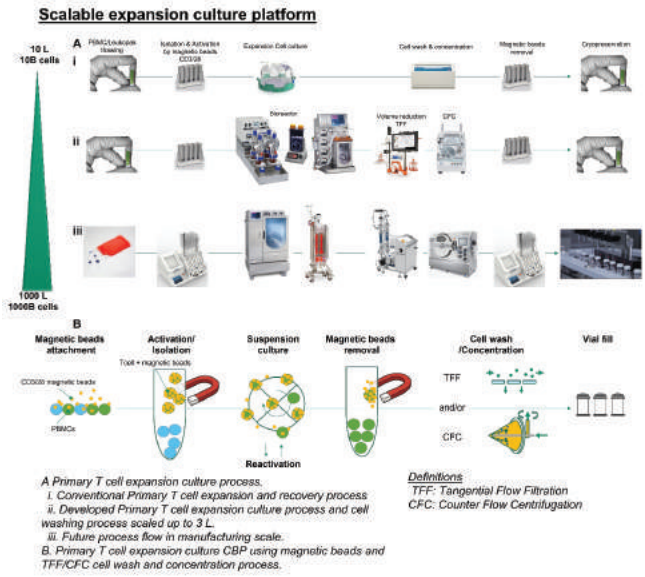
(hAAT) promoter were administered into a murine model to test their expressing capability, respectively. First, to determine the optimal dosage, an initial test was performed by hydrodynamically injecting 5, 10, 20, and 50 μg of dbDNA and plasmid DNA to C57BL6J mice. Mouse plasma samples were collected on day 3, 10 and every 10 days afterwards and hFIX expression levels were evaluated by ELISA. The results showed a clear dose response in plasmid DNA treated group, whereas the mice treated with 20 μg dbDNA had more consistently high expression levels among different dosages throughout the 8 weeks of monitoring period. Thus, we proceeded with 20 μg as the dose of injection in subsequent studies. Next, we screened for the best candidate of hFIX expression cassettes for the dbDNA expression with least toxicity. Mice were hydrodynamically injected with 20 μg of two control plasmid DNAs and five dbDNAs containing various hFIX expression cassettes carrying hFIX cDNA combined with various arrangements of Intron A and 3'UTR. Similarly, the plasma samples were collected on day 1, 3, and every 10 days afterwards. With the same hFIX expression cassettes, dbDNA showed higher expression level of hFIX (1.5-2 folds) compared to plasmid DNA and sustained until the end of the study. With comparison of different expression cassettes, hFIX cDNA combined with Intron A in its natural position or incorporated right after the promoter with an additional 3'-UTR achieved higher expression levels. ALT levels in plasma of all dbDNA and plasmid DNA treated mice transiently elevated initially after hydrodynamic delivery and decreased to a normal range after day 3 of injection until the final collection date. Mouse livers were collected 7 weeks after injection. No significant liver damage was observed in dbDNA or plasmid DNA injected mice by histology analysis of the liver sections. We continue to modify the hFIX expression cassettes in dbDNA by adding various sequences to further enhance the expression levels. Durability and dose ranging will also be monitored to test dbDNA as a long-term, high expressing vector for in vivo gene transfer. These results indicate that dbDNA is potentially a good candidate for nonviral gene transfer.

831 Scalable Expansion Culture of Human Primary T Cells

Tomoaki Kurakazu[1], Sho Sato[1], Ryo Hibino[2], Maki Mifune[2], Daichi Hikimoto[1], Takahiro Oba[2], Hideaki Kagawa[1], Stephen Fischer[1], Tadanori Yamada[1], Rebecca Selzer[1]

[1]FUJIFILM Cellular Dynamics Inc., Madison, WI,[2]FUJIFILM Corporation, Kanagawa, Japan

Autologous T cell-based therapies have rapidly become some of the most promising treatments for blood and other cancers. Despite their clinical success, several obstacles related to the time, cost, and quality of starting from the patients' own T cells have prevented wider accessibility to these life-saving treatments. By contrast, using T cells from healthy donors can potentially provide large amounts of highly functional cells that are less expensive to manufacture and are available "off-the-shelf". To transition allogeneic T cell therapies from research to commercial manufacturing, a scalable and reproducible cell expansion process is important. Moreover, for clinical application, it is advantageous to use a single use, closed and controlled environment. At FUJIFILM Cellular Dynamics, Inc. (FCDI), we have experience in process optimization with various culture formats. We created a closed and scalable 3D culture process for primary T cell expansion and reactivation method using magnetic beads and bioreactors. Under optimized conditions with 3L bioreactor, we achieved over 2000-fold increase after 14 days while maintaining comparable cell quality including immune cell marker expression and viability. In addition, closed cell washing and concentration by counterflow centrifugation was demonstrated with high viability and a recovery ratio over 80%. We also showed assessments using a small-scale bioreactor to show process window of primary T cells for process intensification. Together, these established Primary T cell scale-up and processing methods allow for the routine manufacture of over 1000 billion Primary T cells per batch.



832 Engineered AAV9 Variants for Efficient Muscle Transduction

Shaoyong Li, Shuyuan Chen, Zhongwan Li, Runyuan Zhang, Xing Lan, Yuling Jiang, Yanyan Zheng, Changpeng Wan, Xiaodong Pang, Lijun Wang, Guo-Jie Ye, Zhenhua Wu

Exegenesis Bio Inc., Lower Gwynedd, PA

Systematic administration of Adeno-associated virus (AAV) vectors expressing functional genes represents a promising treatment for muscular dystrophy. However, very high dose of AAV is required due to its low transduction efficiency in the muscle after intravenous delivery. We aim to engineer novel AAV capsids with enhanced transduction efficiency in muscles using our AAVarta platform, an AI-aided AAV capsid evolution discovery technology. Based on AAV9 capsid, random peptide insertion AAV capsid libraries were generated and screened in both mice and non-human primates (NHP). The screening process relies on muscle-specific viral mRNA recovery by using an in-house developed potent synthetic muscle promoter SCC45. After two rounds of screening in 3 mouse strains (C57BL/6, BALB/c and DBA/2j-mdx) and one round in NHP, the top capsid candidates were selected for individual validation. By using GFP and firefly luciferase reporter genes, several variants show dramatic improvements (up to 113 folds) in the mouse skeletal muscles compared to AAV9. One variant AVT913 shows 26-fold enhanced transduction at mRNA level in the heart.

Of note, variant AVT919 shows significant improvements in triceps and tibialis anterior over MyoAAV2A, a benchmark myotropic AAV capsid. Although the majority of top variants show improved muscle transduction and reduced liver targeting, one particular variant AVT908 demonstrates enhanced efficiency in both muscle and liver. To confirm if similar tissue-tropic patterns can be recapitulated in NHP, those variants together with additional candidates were individually packaged and intravenously injected to adult cynomolgus macaques. The characteristic results would reveal the cross-species translatability. We believe that those engineered myotropic AAV capsids would provide efficient delivery platforms for muscle-targeting gene therapy.

833 Selective Ablation of Solid Tumors with Dysfunctional p53 Signaling Using a Suicide Gene Delivered via Fusogenix Proteolipid Vehicles

Douglas Brown[1], Arun Raturi[1], Prakash Bhandari[1], Ping Wee[1], Liliya Grin[1], Hector Vega[1], Maryam Hejazi[1], Paola Solis[1], Jitendra Kumar[1], Jailal Ablack[1], Matthew Scholz[2], Henry Garcia[2], Roy Duncan[3], John D. Lewis[1]

[1]Entos Pharmaceuticals, Edmonton, AB, Canada,[2]OncoSenX, Seattle, WA,[3]Dalhousie University, Halifax, NS, Canada

While chemotherapy is a key treatment strategy for many solid tumors, it is rarely curative as patients will eventually become resistant. In this study, we sought to develop an effective suicide gene therapy approach for solid tumors that specifically exploits the unique transcriptional activation state of the tumor suppressor, p53. We have developed a Fusogenix proteolipid vehicle (PLV) formulation to deliver a plasmid DNA vector where the p53 promoter is included upstream of the inducible suicide gene, inducible caspase-9 (iCasp9). The addition of the small molecule dimerizer agent, rapamycin (RAPA), facilitates cleavage and activation of iCasp9 leading to caspase-mediated apoptosis in cells with elevated p53 promoter activity. We observed a high degree of apoptotic cell death, as measured by live-cell imaging, as well as Annexin V and TUNEL flow cytometry. No cell death was observed in cells with intact p53 such as the fibroblast cell line IMR-90. Systemic delivery of the p53-iCasp9 vector to mice bearing subcutaneous H1299 tumors results in robust apoptosis induction upon activation with RAPA that effectively controls tumor growth over time. When p53-iCasp9 was combined with the anti-CTLA-4 (α-CTLA4) checkpoint inhibitor, treatment was able to reduce the total metastatic burden in the poorly immunogenic B16F10 melanoma lung metastasis model. Treatment correlated with an increase in activated CD4 T lymphocytes and a reduction in suppressive CD4 T_{reg} cells - leading to improved recognition and elimination of B16F10 cells *ex vivo*. In conclusion, we describe a PLV based suicide gene therapy approach for the treatment of cancer with high selectivity for tumors with dysregulated p53 transcriptional activation.

834 Therapeutic Efficacy of Retroviral Replicating Vector Toca 511 (vocimagene amiretrorepvec) -Mediated Prodrug Activator Gene Therapy for Lung Cancer

Kei Hiraoka[1,2], Hiroki Kushiya[1], Tomohiro Suzuki[1], Kazuho Inoko[1,3], Akihito Inagaki[4], Hiroki Niwa[1], Katsunori Sasaki[1], Toru Nakamura[1], Takahiro Tsuchikawa[1], Toshiaki Shichinohe[1], Noriyuki Kasahara[4], Satoshi Hirano[1]

[1]Department of Gastroenterological Surgery II, Hokkaido University Graduate School of Medicine, Sapporo, Japan,[2]Department of Clinical Research, National Hospital Organization Hakodate National Hospital, Hakodate, Japan,[3]University of Minnesota, Saint Anthony, MN,[4]Departments of Neurological Surgery and Radiation Oncology, University of California, San Francisco, San Francisco, CA

Despite the development in recent years of targeted therapy and immune checkpoint inhibitor therapy, lung cancer (LC) remains one of the most lethal cancers, thus new therapeutic strategies are urgently needed. Retroviral replicating vectors (RRV) are capable of highly efficient replication and transduction in cancer cells. Prodrug activator gene therapy with Toca 511 (*vocimagene amiretrorepvec*), an RRV encoding yeast cytosine deaminase (yCD), which converts the prodrug 5-fluorocytosine (5-FC) to the anticancer drug 5-fluorouracil (5-FU) within Toca 511-infected cells, has been shown to achieve significantly enhanced survival benefit in a variety of preclinical tumor models. In an international randomized Phase 2/3 clinical trial for patients with recurrent high-grade glioma, Toca 511/5-FC treatment did not meet its endpoints overall, but demonstrated highly promising evidence of survival benefit in pre-specified patient subgroups. Therefore, we evaluated the therapeutic activity of RRV-mediated prodrug activator gene therapy in LC-derived cell lines and in a preclinical model for metastatic LC.We first quantitated the replication kinetics of RRV in vitro in human (A549, H226, SBC-3) and murine (Ex-3LL) LC cell lines. The percentage of GFP-positive cells were monitored by flow cytometry every 2-3 days after inoculation with RRV expressing GFP as a reporter gene (RRV-GFP) at a multiplicity of infection (MOI) of 0.01. In both human and mouse LC lines, RRV-GFP showed rapid viral replication resulting in high levels of transduction, as indicated by the percentages of GFP-positive cells reaching nearly 90% over time.Next, we evaluated in vitro cytotoxicity by MTS assay after exposure to a series of 5-FC concentrations in LC cells transduced with Toca 511. Compared to controls, Toca 511-transduced A549 and Ex-3LL LC cells showed significant growth inhibition (>80%) after exposure to 1.0 mM and 0.01 mM 5-FC, respectively. Finally, we evaluated the in vivo efficacy of Toca 511/5-FC treatment in subcutaneous tumor models of A549 in immunodeficient athymic nude mice and Ex-3LL in immunocompetent syngeneic mice. In both models, Toca 511-transduced tumors treated with 5-FC showed highly significant growth inhibition compared to control groups ($p<0.0001$). Especially in the Ex-3LL tumor model, 4 out of 5 mice showed complete tumor regression. Furthermore, we established orthotopic pleural dissemination models using luciferase-marked A549 and Ex-3LL tumors to monitor tumor burden by optical imaging of tumor bioluminescence. As compared with their respective control groups, the Toca 511/5-FC treatment group showed significant reductions in mean signal intensity in both A549 ($p=0.0147$) and Ex-3LL ($p=0.0326$) models. Thus, RRV can serve as highly efficient vehicles

for gene delivery to LC, and these in vitro and in vivo data indicated the translational potential of RRV-mediated prodrug activator gene therapy with Toca 511/5-FC as a novel therapeutic strategy for pulmonary malignancies.

835 Modification of the AAV Serotype rh.10 Capsid to Enhance CNS Gene Transfer

Kalpita R. Karan, Slawomir Andrzejewski, Katie M. Stiles, Neil R. Hackett, Ronald G. Crystal

Department of Genetic Medicine, Weill Cornell Medicine, New York, NY

Nonhuman primate serotype AAVrh.10 has been demonstrated to effectively transfer genes to the CNS following direct administration (Sondhi D et al, Sci Trans Med 2020; 12: eabb5413) or via cerebrospinal fluid (Rosenberg JB et al, Hum Gene Ther Clin Dev 2018; 29:24). We hypothesized that, for a given dose, CNS distribution of AAVrh.10 could be further improved by genetic modification of capsid loop IV with sequences designed to broaden distribution. Following initial screening of multiple variants, the AAVrh.10S2 capsid was selected, where amino acids 452-459 in loop IV were replaced with DGAATKQ, a sequence modified from AAV9 CAP-B10 (Goertsen D et al, Nat Neurosci 2022; 25:106). AAVrh.10S2 coding for mCherry was assessed *in vitro* in cell lines U87 (glioma), SVGp12 (glial) and SH-SY5Y (neuroblastoma) and *in vivo* following direct intrahippocampal administration of AAVrh.10S2mCherry to C57Bl/6 mice. In all neural cell lines, expression of mCherry was significantly greater (average 5.8-fold all cell lines) for AAVrh.10S2mCherry than for the same dose (10^4 gc/cell) of the wildtype AAVrh.10mCherry control ($p<0.05$, all cell types). CNS expression of mCherry was assessed 4 weeks following intrahippocampal administration of $2.5x10^{10}$ gc of AAVrh.10S2mCherry compared to AAVrh.10mCherry. With the same dose, mCherry mRNA levels in the hippocampus and cortex were higher with AAVrh.10S2 mCherry compared to AAVrh.10mCherry (hippocampus 55-fold, cortex 7.6-fold; $p<0.05$ by ANOVA). Consistent with the mRNA data, protein expression with AAVrh.10mCherry in the hippocampus was 17.7± 2.6 ng/μg protein and 5.9± 0.5 ng/μg in the cortex. In contrast, with the same dose, hippocampus mCherry levels with AAVrh.10S2mCherry were 39.8 ± 1.8 ng/μg and in the cortex were 17.7± 2.2 ng/μg, >2-fold higher than with the unmodified AAVrh.10 vector ($p<0.001$ by ANOVA). In summary, the modified AAVrh.10S2 capsid has enhanced CNS distribution *in vivo*, providing greater brain transduction compared to unmodified AAVrh.10 capsid following direct intraparenchymal administration. Pending assessment in larger species, the AAVrh.10S2 capsid may be useful for treating diffuse neurological diseases.

837 Ultra-Pure Single Molecule Guide RNAs for Therapeutic CRISPR Gene Editing

Xiaoyun Lin[1], Qiong Zhao[2], Ranga Srinivasan[1], Ju-Tao Guo[2], Minghong Zhong[1]

[1]GeneLancet Biosciences, Inc., Doylestown, PA,[2]Baruch S. Blumberg Institute, Doylestown, PA

The clustered regularly interspaced short palindromic repeats (CRISPR) gene editing has an intriguing potential to cure many diseases of unmet needs. A CRISPR gene editor is composed of Cas protein(s) and guide RNA(s), and the spacer sequence in the guide RNA (gRNA) determines where the editor introduces genetic changes. Therefore, it is crucial that these gRNAs have minimum impurities such as truncated byproducts, including n+1, n-1, n-2, and n-3 in particular, all of which bind to Cas proteins leading to un-intended genetic modifications. High-efficiency off-target editing is well-documented in the literature. It was reported that chemical modifications improved the on-target editing efficiency while decreasing the off-target editing. Guide RNAs can be produced either in cells from delivered plasmids or by in vitro transcription, both of which do not allow chemical modifications. Chemical synthesis provides unique access to modified gRNAs. Nowadays, automated solid phase synthesis of oligonucleotides of ~20 nt in length works at kilogram scales; however, it is still a daunting challenge for long RNA molecules because of their 2'-OH groups. With the recent new development of 2'-protecting groups, 25~35% crude yields for syntheses of 100mer sgRNAs were reported, which was equivalent to 98.6~98.9% stepwise coupling efficiency. Obviously, to deliver high-grade sgRNAs, we must overcome two major barriers, namely low overall yields and extremely difficult purification. To evaluate the efficacy of truncated guide RNAs, we have synthesized 92mer (n+1), 90mer (n-1), 89mer (n-2), and 88mer (n-3) of a chemically ligated guide RNA (l2gRNA, 91mer) targeting HBV genome. The ligation groups were introduced at the final coupling step (5'-end), and thus most of the truncated segments were not reactive and remained after ligation. The product composing a single spacer sequence was ensured by careful polyacrylamide gel electrophoresis (PAGE) separations of the crRNA segment (32 nt) and optional PAGE separations of tracrRNA segments (36 nt and 23 nt), followed by chemical ligations and one additional PAGE purification for the final products. These l2gRNAs were then mixed on purpose and submitted for LC-MS analysis. Our data indicated, in comparison to good resolutions of short RNA segments, these products gave one overlapped sharp peak in HPLC trace as reported in the literature, and that because of many charged states of molecular ions and adducts, it is very challenging to develop a universal standard analytical method to quantify the product purities. In addition, the truncated lgRNAs showed only slightly decreased or similar efficacy (80~91%) as the full-length l2gRNA (95%) in AD38 Cas9 stable cell line. Based on these data, we caution that chemically synthesized long guide RNAs, in particular, sgRNAs (~100 nt) and pegRNAs (>120 nt), contain assemblies of inseparable truncated byproducts of various spacer sequences, which can give rise to unpredictable off-target editing. LgRNA technology provides scalable and efficient access to ultra-pure long guide RNAs, which are critical for clinical applications.

838 Interleukin-15 and Interleukin-2 Promote Persistence of FcεRIγ Negative (g-NK) Natural Killer Cells in Mice

Shalaleh Masoumi[1], Austin B. Bigley[2], Shanae Spade[2], Sana Sharif[1], Michelle Spruill[1], Muhammad H. Malik[1], Luona Yang[1], Nadia Agha[2], Mariam Khalil[2], Lyle Babcock[2], Jenna Recker[2], Rachel Bates[2], Guy Dipierro[2], Xinli Liu[1]

[1]Department of Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX,[2]Indapta Therapeutics, Houston, TX

Purpose: Natural killer (NK) cells have intrinsic abilities to identify and eliminate tumor cells and virally infected cells. Enhancing the potency of therapeutic NK cells and improve their in vivo persistence are critical for the success of NK cell immunotherapy. A subset of human NK cells lacking expression of FcεRIγ (g-NK cells) is known to have a multifold increase in antibody-dependent effector functions after CD16 crosslinking. We sought to evaluate the in vivo persistence of g-NK cells with interleukin-15 (IL-15) and interleukin-2 (IL-2) treatment in mice. **Methods:** g-NK cells ($CD45^+7\text{-}AAD^-CD3^-CD56^+Fc\varepsilon RI\gamma^-$ lymphocytes) were expanded from cryopreserved PBMCs using a published method. A single dose of 1.0×10^7 expanded g-NK (freshly expanded or cryopreserved) or conventional NK cells (cNK, cryopreserved) was injected intravenously through the tail vein into 6-8 weeks old female NSG mice. Mice immediately received either recombinant human IL-15 (2 μg/mouse intraperitoneally every 3 days, n=9 mice) or human IL-2 (10 μg/mouse intraperitoneally every 2 days, n=6 mice). Peripheral blood (50 μL) was drawn at post-cell injection days 6, 16, 26, and 31 for IL-15 treated mice and days 3, 6, 12, 19, 26, and 33 for IL-2 treated mice for immediate flow cytometric analysis of g-NK cells. Mice were euthanized on day 31 and 33 for IL-15 and IL-2 treatment, respectively. Mice body weights were monitored every other day throughout the study. **Results:** In the IL-15 treated mice, persistence of cryopreserved g-NK cells was > 10 times higher than that seen with cryopreserved cNK cells in peripheral blood at days 6, 16, 26, and 31 post cell injection ($P < 0.001$). Persistence of g-NK cells were also higher than that of cNK cells in spleen and bone marrow when the mice were euthanized at day 31 ($P < 0.001$). Cyropreserved g-NK cells persisted at levels comparable to that in fresh g-NK cells for at least 26 days post cell transfer. In the IL-2 treated mice, after single dose of cryopreserved g-NK injection, the blood g-NK cell numbers increased significantly and peaked at day 12 post cell injection, then dropped slowly from day 19-33. Both IL-15 and IL-2 treatments have minimal impact on the body weight of mice compared to untreated control mice within the study period indicating minimal systemic toxicity. **Conclusion:** Both IL-15 and IL-2 are effective in enhancing in vivo persistence of g-NK cells with minimal systemic toxicities. Cryopreserved g-NK warrants further evaluation as an off-the-shelf cell immunotherapy.

840 Anti-AAV1 Antibodies Do Not Inhibit Neuronal Transduction after Direct Brain Administration with AAV1

Geena Skariah

Neuroscience Discovery, Janssen R&D, Spring House, PA

Adeno-associated viruses (AAVs) are the leading vectors of choice for gene therapy. One limitation of these vectors is that recombinant AAV vectors are derived from their wild-type counterpart, which can naturally infect humans and give rise to anti-AAV antibodies. These anti-AAV antibodies adversely impact gene therapy outcomes because they inhibit transduction efficiency, and preclinical research animals and human patients must be carefully screened for anti-AAV serum titers. Whether anti-AAV serum titers are relevant in immune-privileged locations such as the brain is still an open question. To address this question, we developed an experimental strategy to evaluate the impact of anti-AAV1 antibodies on neuronal transduction in the Long Evans (LE) rat brain. Specifically, we injected LE rats intramuscularly with either empty AAV1 capsids or PBS as a control. Two weeks later, we used blood serum samples to confirm the presence of anti-AAV1 antibodies, and a strong anti-AAV1 response was observed in rats that received the empty AAV1 capsid injections. We then delivered AAV1-CAG-eGFP (1e10 GC delivered in 2 μL) unilaterally directly into the substantia nigra (SN) and analyzed GFP expression at 4 months post-injection by immunofluorescence. There was no difference in GFP expression in the SN between the two groups of rats suggesting that the presence of anti-AAV1 antibodies in the periphery does not decrease neuronal transduction after direct brain delivery. This knowledge can inform us about patient inclusion in clinical trials for AAV-based gene therapy for neurological disorders when the vector is delivered directly into the brain. Though we also found that AAV1 injection into the brain results in the production of anti-AAV titers in serum, we would not expect this Anti-Drug-Antibody (ADA) induction to limit future CNS AAV re-dosing.

841 Efficient Mini dCas13-Mediated Base Editing for Personalized Treatment of Duchenne Muscular Dystrophy

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China,[3]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[4]Lingang Laboratory, Shanghai, China,[5]Shanghai Research Center for Brain Science and Brain-Inspired Intelligence, Shanghai, China

Background: Approximately 10% of monogenic diseases are caused by nonsense point mutations that generate premature termination codons (PTCs), leading to a truncated protein and nonsense-mediated decay of mutant mRNAs. Specifically, ~50% of these point mutations can be reversed by A to G conversion with adenine base editors (ABE) to restore protein expression. Here, we demonstrate a mini-dCas13X-mediated RNA adenine base editing (mxABE) strategy to treat nonsense mutation-related monogenic diseases via A-to-G editing in a genetically humanized mouse model of Duchenne muscular dystrophy (DMD). **Methods**: We identified a nonsense point mutation (c.4174C>T, p.Gln1392*) that introduced a PTC in the *DMD* gene exon 30 of a patient and validated its pathogenicity in a genetically humanized DMD murine model ($DMD^{Ex30mut}$). A single adeno-associated virus (AAV) containing mxABE was delivered to $DMD^{Ex30mut}$ mice to correct the PTC mutation in the *DMD* gene. To further demonstrate the efficacy and safety of the single AAV-packaged

mxABE strategy in large mammals, two gRNAs flanking porcine *DMD* gene exon30 were designed, and porcine fetal fibroblasts (PFFs) isolated from a 30-day-old fetus of Duroc pig were transfected with donor template and CRISPR plasmids. Forty-eight cell lines that exhibited good morphology and viability were carefully singled out, and two knock-in cell lines were pooled and used as nuclear donors to produce the DMD porcine models. **Results**: In this humanized DMD^{E30mut} mouse model, a single AAV-packaged mxABE reached A-to-G editing rates up to 84% *in vivo*, much higher (at least 20 folds) than that reported in previous studies using other RNA editing modalities (Fig. 1A,B). Furthermore, mxABE restored robust expression of dystrophin protein to over 50% of wildtype level by PTC read-through in multiple muscle tissues. Importantly, systemic delivery of mxABE by AAV can also rescue dystrophin expression (37% in diaphragm, 6% in tibialis anterior and 54% in heart muscle on average, compared to wildtype level) (Fig. 1C), serum creatinine kinase levels and muscle function and muscle function (Fig. 1D, E and F). **Conclusions**: These data suggested mxABE may overcome the current limitations of the CRISPR system for the treatments of DMD and other monogenic diseases. Continued development of this mxABE approach for DMD in large animals may provide an essential step toward the clinical translation of alternative gene-editing technology in the near future.

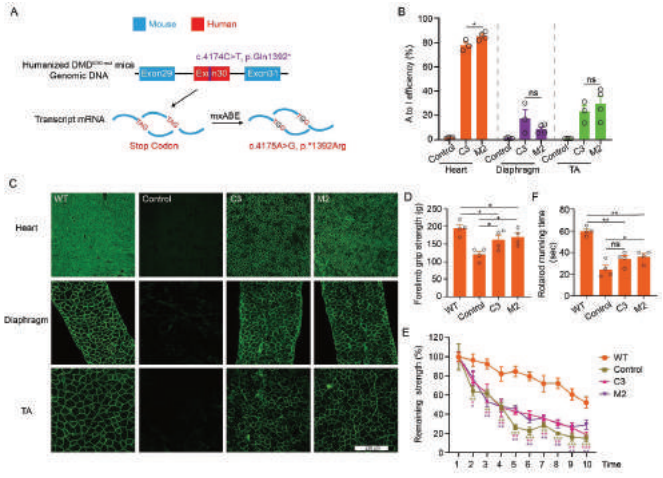

Figure 1. Systemic delivery of AAV-mxABE rescues dystrophin expression and muscle function in multiple organs.
A, Schematic diagram of nucleotide editing strategy in humanized DMD mice. The mutation exon30 generated a premature stop codon, and can be corrected by mxABE system. B, Measurement by deep sequencing of dystrophin transcripts of the targeted A to I editing efficiency in TA, Diaphragm , and heart (n=4). C, Immunohistochemistry analyses shows restoration of dystrophin expression in the TA, Diaphragm, and heart of DMD^{E30mut} mice 6 weeks after injection. Dystrophin was shown in green. Scale bar, 200 μm. Forelimb grip strength (D), Rotarod (E) and remaining strength (F) were measured in WT, DMD^{E30mut} mice, and DMD^{E30mut} mice treated with AAV particles (n=6). Data shown as mean ± SEM. Different asterisks represent statistical significance (P<0.01) in multiple comparison test using ANOVA.

842 *In Utero* Lipid Nanoparticle Targeting of the Fetal Skin for mRNA Therapies

William Johnston[1], Marco Carpenter[2], John Riley[1], Valerie Luks[1], Cara Berkowitz[1], Nicole Kus[1], Ana Dumitru[1], Rohan Palanki[1], Mohamad Gabriel Alameh[2], William Peranteau[1]

[1]Children's Hospital of Philadelphia, Philadelphia, PA,[2]University of Pennsylvania, Philadelphia, PA

Introduction: The rationale for therapeutic in utero gene editing is to harness normal developmental ontogeny to institute therapy in a more efficient and safe manner prior to the onset of pathology. Among the properties of the fetus that make it attractive for *in vivo* gene editing is the abundance and accessibility of progenitor cells, including stem cells of organs that are difficult to target after birth. The skin exemplifies this premise with genetic skin disorders, such as epidermolysis bullosa, often leading to diffuse blistering shortly after birth. Critical to harnessing the potential of new gene editing and mRNA therapies for such diseases is the ability to diffusely and efficiently target skin epithelial progenitor cells. In the current study we assess the ability of lipid nanoparticles (LNPs) delivered to the amniotic cavity in a fluorescent reporter mouse model to target the fetal skin. We hypothesize that fetal skin has an increased amount of stem cells relative to neonatal skin and that fetal skin stem cells can be readily targeted by intra-amniotic (IA) delivery of LNPs in a gestational age dependent manner. **Methods:** We performed IA injection of LNPs containing Cre recombinase mRNA (LNP-Cre) into mTmG heterozygous fetuses at gestational day (E) 12 (n=10) and E16 (n=10), as well as control IA PBS injections at E12 (n=10). mTmG mice express GFP in all cell types following Cre mediated excision of the mT gene. After birth, mice were harvested at postnatal day (P) 1, 7, and 30 with skin assessed for GFP expression by fluorescent stereomicroscopy and flow cytometry. Additionally, skin of uninjected mTmG heterozygous mice was harvested at E14 and P1 and the relative abundance of CD34+ bulge stem cells was quantified by flow cytometry. **Results:** Mice injected at E12 and imaged at P1 demonstrated a stippled pattern of GFP expression on the scalp and extremities that extended linearly down the abdomen and back with scattered areas of hyperintensity. By P7 these mice demonstrated diffuse GFP expression across the entire body that persisted at P30. In contrast, experimental mice injected at E16 and control mice demonstrated no editing. For injected E12 mice, flow cytometry at P7 demonstrated an average of 5% editing of CD34+ bulge skin stem cells, while control and E16 injected mice had no editing. Additionally, flow cytometry of skin harvested from uninjected mice at E14 demonstrated a greater proportion of CD34+ stem cells compared to skin harvested at P1 (7.66 vs 0.86%, p=0.0003). **Conclusion:** Mouse fetal skin, including bulge skin stem cells, is accessible for mRNA delivery via intra-amniotic LNP injection. The efficiency of skin stem cell targeting is highly dependent on the gestational age at which the LNP is injected, with increased efficiency earlier in gestation likely reflecting the development of a protective keratinized skin layer later in gestation. These studies suggest a possible LNP approach to deliver therapeutics to the skin for genetic diseases.

843 A Cell Subtype-Mediated Mechanism Informs Cell Therapy Strategy for Discogenic Low Back Pain

Wensen Jiang, Juliane Glaeser, Giselle Kaneda, Jacob Wechsler, Stephen Stephan, Khosrowdad Salehi, Julie Chan, Wafa Tawackoli, Pablo Avalos, Christopher Johnson, Chloe Castaneda, Linda Kanim, Teerachat Tanasansomboon, Joshua Burda, Oksana Shelest, Tiffany Perry, Michael Kropf, Hyun Bae, Laura Stone, Haneen Yameen, Jason Cuellar, Dror Seliktar, Dmitriy Sheyn

Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: Low back pain (LBP) is a leading cause of disability affecting almost 80% of the adult population, and 40% of LBP is attributed to intervertebral disc (IVD) degeneration. However, radiographic signs of IVD degeneration do not always correlate with painful discs. The mechanisms that determine which degenerated discs drive the pain are yet to be fully revealed. Loss of nucleus pulposus cells (NPCs) correlates with disc degeneration. We hypothesize that NPC affected by specific environmental stressors trigger the onset of low back pain. **Methods**: Degenerated IVD tissue freshly harvested from surgical discards or human cadavers with approved protocols were compared with single-cell RNA-seq (scRNA-seq), including 3 **back pain-inducing** IVDs (**bpIVD**) and 4 **asymptomatic** IVDs (**aIVD)** from different individuals. Further subset NPCs from bpIVD (**bpNPC**) or aIVD (**aNPC**) for further analyses. Replated aNPCs in 2D tissue culture and transformed them from non-stressed status (**nsNPC**) into a stressed status (**sNPC**) by applying pro-inflammatory cytokine IL-1β, low pH, and low glucose. Nociception-activating effects of nNPC and nsNPC in were determined in vitro in a co-culture with iPSC-derived nociceptors (**iNOC**) using microfluidic devices. The sNPC, nsNPC, and saline were injected into healthy rat IVDs followed by μMRI and biobehavioral tests for up to 8 weeks. Post-sacrifice, IVDs were harvested and evaluated for nociceptive markers expression and histology IHC. For statistics, 3-way ANOVA and a critical significance level of 5% was used. **Results:** ScRNA-seq identified NPCs as the major cell type affected by LBP condition (Fig. 1A). Some clusters, particularly NPC1^{MMP3+}, were found associated with bpIVDs because 62% cells of this subtype were derived from bpIVDs (Fig. 1A). A pseudo-time trajectory analysis shows the trend from aIVD-associated NPC7 to aIVD-associated NPC6, and a bpIVD-associated NPC1 side branch in the middle (Fig. 1B). Within NPC1 subtype, the cells solely derived from bpIVD were annotated as **bpNPC1** and further examined along with NPC6 and NPC7 cells derived from aIVD (Fig. 1C). The **bpNPC1** subset showed the upregulated nociception and neuron outgrowth regulated by NGF. These data suggest that NPC1 cluster might be the pain-inducing cell subtype. We recreated the NPC1 subtype with combinatory stimulation of NPCs *in vitro* with cell stressors (Fig. 1D) resulted in an upregulation of TNF-α, IL-1β, IL8, MMP3, and NGF (Fig. 1E). sNPC showed bpNPC1-like transcriptomes as evidenced by 1) more overlap of expressed genes with bpNPC1 than bpNPC (Fig. 1F) and 2) more bpNPC1-like MMP3 expressions than nsNPC (Fig. 1G). The sNPC induced functional response from iNOC but nsNPC did not (Fig. H- N). In the animal study, the intradiscal injection (Fig. 1O) led to expression of nociceptive markers TRPV1, Gap43 and CGRP only in sNPC-injected group (Fig, 1P) and increased nociceptive behavior compared to nsNPCs or saline-injected groups (Fig. 1Q). **Conclusion**: This study discovered that a subtype of NPC generated under stress are responsible for discogenic low back pain. This NPC-mediated pain mechanism will inform future NPC-focused clinical therapies that are more approachable than regenerating the entire IVDs.

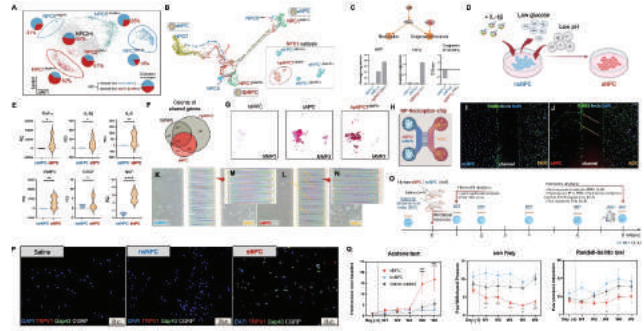

*Fig. 1. (A) NPC cell atlas in IVDs. Pie charts show cell percent derived from different IVDs. (B) Pseudo-time trajectory shows the developmental direction among subtypes. Terminal s, B, and C are dominated by sNPC, bpNPC, and aNPC respectively. (C) NGF-regulated network for bpNPC1 predicted with Qiagen IPA. 844 Ministring DNA Encoding Human Factor VIII Gene: A Novel Paradigm of Nonviral Gene Therapy for Hemophilia A Patients

Ting-Yen Chao[1], Meng-Ni Fan[1], Ko Currie[2], Xiaohe Cai[1], Yuanyi Xu[1], Roderick Slavcev[2,3], Nafiseh Nafissi[2,3], Carol H. Miao[1,4]

[1]Seattle Children's Research Institute, Seattle, WA,[2]Mediphage Bioceuticals, Toronto, ON, Canada,[3]University of Waterloo, Waterloo, ON, Canada,[4]Department of Pediatrics, University of Washington, Seattle, WA

Ministring DNA (msDNA) is a novel double-stranded linear DNA minivector with covalently closed ends. The DNA minivector eliminates bacterial plasmid sequences and any CpG motifs, conferring a safe, redosable, and effective non-viral gene delivery profile. Hemophilia A is a genetic disorder caused by missing or defective coagulation factor VIII (FVIII gene) protein, whereby gene therapy represents a promising treatment approach to correct this disorder. However, there is unmet need for a controlled and titratable gene therapeutic for HemA patients. We evaluated and optimized the FVIII construct (HP-hFVIII) that was integrated into the msDNA platform to achieve the advantages of a safe and redosable genetic medicine. The msDNA encoding human FVIII (hFVIII) gene with a hepatocyte specific promotor (msDNA-HP-hFVIII) was generated (8.1kb) from the plasmid pHP-hFVIII (10kb). An msDNA construct, msDNA-CAG-W-hFVIII driven by the ubiquitous, highly efficient promoter CAG (7.2 kb) served as the vector control. We evaluated the impact of genetic regulatory sequences in a dose-dependent manner. Groups of immunocompetent murine FVIII knock out mice (Hem A mice) had 1 μg (0.04 mg/kg) of respective msDNAs and the parent plasmid, pHP-hFVIII, administered via hydrodynamic injection. The plasma of the treated mice was collected on days 1, 7, 14 and each subsequent 14-day period to examine FVIII activity in treated mice via activated Partial Thromboplastin Time (aPTT) tests. On day 1 post-vector administration, the Hem A mice treated with 1 μg msDNA-HP-hFVIII produced more than 4,000% wild type level of FVIII activity wild type levels in human plasma defined as 100%). Relative to plasmid, msDNA generated 4-fold higher FVIII. In

addition, the mice treated msDNA-CAG-W-hFVIII exhibited 14,000% FVIII activity. However, the high levels of human FVIII expression rapidly induced high levels of anti-hFVIII inhibitor titers, resulting in elimination of FVIII expression to undetectable levels in less than one month. To avoid inhibitor formation, we reduced the DNA dose from 1 μg to either 0.2 μg or 0.04 μg (0.008 or 0.0016 mg/kg, respectively). In the 0.2 μg group, only msDNA-CAG-W-hFVIII treated mice developed inhibitors, whereas both msDNA-L6-hFVIII and pHP-hFVIII treated group had persistent expression levels around 300% and 100%, respectively without antibody formation for over 6 months (experimental duration). Similar trends were observed in the 0.04 μg groups. In particular, mice treated with 0.04 μg msDNA-HP-hFVIII produced sustained levels of FVIII activity (around 100%) more than 6 months post-single systemic administration. In all cases, msDNA showed significantly higher FVIII levels compared to the plasmid DNA (>3-fold). The results revealed a linear dose-dependent response and the durability of FVIII expression in the msDNA-HP-hFVIII treated mice following a single treatment. In conclusion, a single hydrodynamic delivery of the hepatocyte specific msDNA-HP-hFVIII in Hem A mice was highly efficient and the FVIII expression was stable for more than half year. The novel msDNA platform with large human FVIII gene expression cassette (2-times larger than AAV capacity) can provide a safe, efficacious, titratable, and redosable genetic medicine for the treatment of HemA patients.

845 Development of Regulatory Cassettes for Gene Therapies Targeting Muscle Stem Cells

Niclas E. Bengtsson[1], Jeffrey S. Chamberlain[1], Stephen D. Hauschka[2]

[1]Department of Neurology, University of Washington, Seattle, WA,[2]Department of Biochemistry, University of Washington, Seattle, WA

Our group has developed several methods to express therapeutic genes in striated muscle, with a primary focus on establishing effective treatments for Duchenne muscular dystrophy (DMD). These have focused on restoring expression of dystrophin in cardiac and skeletal muscles using Adeno-associated viral (AAV) vector-mediated gene transfer of synthetic dystrophins, or via editing of the endogenous dystrophin gene using CRISPR/Cas9. To ensure efficient and specific expression of AAV delivered genes in postmitotic striated muscles, our approaches utilize in-house developed muscle-specific expression cassettes (MSECs). While resulting dystrophin expression levels and improvements in muscle pathophysiology have been impressive, sustained long-term therapeutic efficacy could benefit greatly from effective co-treatment of muscle stem cells (MuSCs). The therapeutic value of AAV gene transfer to MuSCs has historically been viewed as minimal due to the rapid dilution of therapeutic vector genomes that would occur in dividing stem- and progenitor cells during regeneration of dystrophic skeletal muscle. However, gene editing uniquely enables genomic modifications in MuSCs to be inherited by resulting progeny that either differentiate to repair injured muscle, or return to quiescence as MuSCs for future regenerative needs. Therapeutic MuSC editing is particularly applicable to DMD, due to an abundance of proliferating muscle stem- and progenitor cells responding to continuous bouts of injury and regeneration within dystrophic skeletal muscles. Other groups have reported enhanced therapeutic efficacy and longevity following dystrophin gene editing in MuSCs or progenitors. These studies demonstrate that at least some MuSC populations or progeny thereof can be transduced by AAV vectors, but have relied on ubiquitous and/or non-specific gene regulatory cassettes (RCs) to control editing activity. Non-specific editing approaches are troublesome for future use in patients, not merely based on immunogenicity, but particularly when targeting mitotically competent cells in which unintended editing side-effects could cause detrimental outcomes such as malignancies. MuSC-specific RCs could minimize such outcomes by eliminating potential oncogenic editing of non-target genes or cell types. To address the need for MuSC-active RCs, we have expanded our AAV-size-compatible library of muscle-specific RCs to include RCs with specific activities in muscle stem- and progenitor cells. Here we describe several synthetic RCs derived from highly conserved MyoD1 and Pax7 gene regulatory sequences (two transcription factors involved in the activation or maintenance of quiescent MuSCs). Our studies identify several candidate RCs with preferential activities in myogenic stem- and progenitor cells that are derived solely from MyoD1 or Pax7, as well as from chimeric combinations of regulatory elements from both genes. Safe and effective targeting of MuSCs using promising RC candidates from this study will be instrumental in addressing current limitations of *in vivo* skeletal muscle gene editing, and will help realize the full potential of gene editing for many genetic muscle diseases.

847 Full Characterization of Encapsidated Nucleic Acid Sequence in AAV Manufacturing Using NGS

Bradley Hasson

MilliporeSigma, Rockville, MD

Adeno-associated viruses (AAV) are one of the most widely used viral vector-based gene therapy delivery systems in the industry. The manufacturing of such products commonly involves complex steps where a series of 3-4 plasmids are transfected into a producer cell line in order to assemble the viral particles. Each plasmid contains a critical element for viral production, whose product is an AAV particle containing the gene of interest flanked by two inverted terminal repeat (ITR) regions. Due to the nature of AAV particle production and DNA packaging, additional non-targeted sequences may be packaged along with the gene of interest. Even in an optimized system, these non-target nucleic acids can comprise between 1-2% or greater of the entire nucleic acid payload of the particle. These non-target elements generally consist of either host cell DNA or transfected plasmid sequences used for the AAV production. Characterizing the non-targeted sequences that may be packaged in the vector is important for establishing the safety profile of the final product. Although PCR methods directed at detecting common process residual DNA sequences can be adapted for this purpose they may not provide the full information of what is contained in the vector. However, Next Generation Sequencing (NGS) can provide a broader characterization of the non-targeted sequences packaged in the AAV particle. NGS is becoming a widely used tool in biosafety testing strategies for viral and gene therapy products. NGS can be used to create a full genetic profile of all nucleic acids contained within the test sample which can then be assessed using an array of bioinformatic analyses. Vector identity confirmation and variant detection is one of the more common applications, however the data generated by NGS methodology can

provide much more information if mined appropriately. In the case of evaluating encapsidated residual sequences, the AAV sample is first treated with DNase to remove any non-encapsidated residual DNA from the viral preparation. The NGS procedure is then performed on intact viral particles to generate the genetic profile of all encapsidated nucleic acids. After bioinformatic subtraction of the expected AAV sequence, non-target DNA sequences can be assessed and characterized, providing a clearer picture of all encapsidated sequences within the AAV particles. In this presentation the characterization of several representative AAV molecules using this process will be discussed, including the sequencing process, bioinformatic analysis, and representative results. Concepts for the determination of nucleic acid content of full, partial, and empty capsids will also be explored.

848 Safety Profiling of AAV-Based Vectors *In Vitro* - Detection of Differentiated Transcriptomic Signatures in Transduced Primary Human Hepatocytes

Hans Peter Rottensteiner[1], Vladimir Galatenko[2], Alicia Rosell-Hidalgo[3], Stefanie Wurm[1], Timur Samatov[2], Gleb Goussarov[2], Ievgen Strielkov[2], Patrice Douillard[1], Werner Höllriegl[1], Paul Walker[3], Rüdiger Fritsch[2], Friedrich Scheiflinger[1], Helmut Glantschnig[1]

[1]Evotec Gene Therapy GmbH, Orth/Donau, Austria,[2]Evotec International GmbH, Göttingen, Germany,[3]Cyprotex Discovery Ltd, an Evotec Company, Alderley Park, United Kingdom

Multifactorial dose-related toxicities following treatments with AAV-based gene therapies have emerged in clinical trials and have raised concerns with regulators and health care providers. The reported adverse events are not limited to specific vectors, although liver toxicities are prominent and have led to discontinuation of clinical trials and serious events caused by already approved products. However, the exact molecular pathologies leading to elevated liver enzymes, serious liver injury, and liver failure remain largely elusive. Clinical safety issues are poorly predicted by testing in preclinical tox species due to differences in biodistribution, transduction efficiencies, payload expression/clearance, and immunogenicity among others. Based on predictive Drug-Induced-Liver-Injury transcriptomics, we set out to build a defined *in-vitro* platform applicable to RNA sequencing of transduced human liver cells, with the aspiration to add molecular insights to vector safety assessments, aided and informed by transcriptomics profiling. Human liver cell lines (HepG2, HepaRG) and primary human hepatocytes (PHH) were seeded in 384-well plate formats and transduced by AAV2, AAV6, AAV8 and AAV9 based vectors expressing a *gfp* or *luc* reporter transgene (N= 8-16/treatment). Control treatments included buffer controls and treatment with empty capsid (N=8-32/treatment). Time-course studies (up to 4 days) and vector titrations (MOI) were used to optimize transduction efficiencies and cell viabilities assessed by quantitative imaging and ATP measurements. All vectors transduced human liver cells, albeit with varying efficiencies (AAV6>AAV2>>AAV8>AAV9) and PHH were selected for transcriptomic profiling. RNA was isolated and subjected to unbiased high throughput RNA-Sequencing (htRNA-Seq). htRNA-Seq was done using ScreenSeq platform, quantifying expression levels for ca. 10,000 genes in a sample. Differential expression and Gene Ontology (GO) enrichment analysis (e.g., assessing stress response and effect on other intrinsic pathways) was done using a ML/AI supported bioinformatics platform (PanHunter). htRNA-Seq enabled reliable phenotype-independent quantification of transgene expression, with sensitivity similar to or higher than sensitivity of e.g., fluorescence-based quantification. More importantly, htRNA-Seq allowed for unbiased analysis of transcriptomic response to transduction with a correlation between MOI and strength of transcriptomic response. A clear separation of response into transgene-independent and transgene-specific components was identifiable in PHH transduced by AAV expressing reporter genes. Enriched GO terms for transgene-independent response components were identified in AAV transduced PHH. In summary, this preliminary study demonstrates that in AAV-transduced PHH quantification of transcriptomic changes provides insight into differentiated responses to AAV vectors and their payloads that can be decomposed in transgene independent and transgene specific components. Further studies will aim to expand this approach into liver micro-tissues and cocultures of mixed cell types with a special view on ML modelling to predict safety liabilities.

849 Single-Base Specific CRISPR Targeting of TERT G228A Mutation with Near-Cognate sgRNA

Hyomin Lee[1], Seohyun Kim[2], Sojin Kim[3], Juyoung Hong[4], Tageun Bae[5], Heonseok Kim[6], Yohan An[4], Seung Hwan Lee[7], Hye Ran Koh[2], Junho Hur[1], Chul-Kee Park[8]

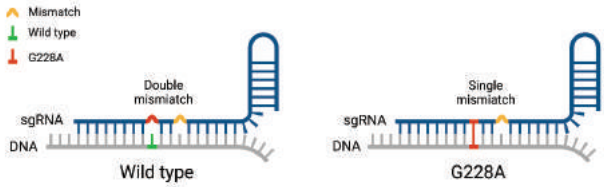
Telomerase regulates the telomeres which are nucleoprotein complexes essential for chromosomal integrity. The telomeres are shortened with each cell division when telomerase is inactivated. In cancer cells, the telomere is maintained by abnormally reactivated telomerase and contributes to cell survival and immortalization. Telomerase Reverse Transcriptase (*TERT*) is activated in cancers through the acquisition of mutation in the *TERT* core promoter region which signifies the most common noncoding mutation. In various cancer types, mostly glioblastomas (80-90%), telomerase is highly expressed dues to overexpression of the *TERT* gene. *TERT* is a druggable and effective target to develop cancer therapeutics.To block telomerase activity, several strategies have been developed including Imetelastat, these have a side effect that can also affect normal cells. To overcome this problem, we address to develop a CRISPR system targeting the *TERT* G228A mutation that promotes cancer development without normal cells. In this study, we deliberately substitute a base of sgRNA to target *TERT* G228A and examined the efficiency of modified sgRNAs through in vitro cleavage screening. Single-molecule analyses showed that the selective binding of the near-cognate sgRNA with a deliberate single-

base mutation to the G228A mutant allele enables the discrimination of the single-base difference. The near-cognate sgRNA also showed highly specific gene editing of the G228A mutant allele in dual fluorescence reporter assessment. Next lentivirus-mediated expression of the near-cognate sgRNA resulted in highly selective targeting of G228A mutant alleles in glioblastoma cell lines, with reduced off-target effects. Together the results suggested the therapeutic potential of CRISPR genome editing with the near-cognate sgRNA.



850 Investigating the Role of Vector DNA Sensing and Transgene Expression on Innate Immune Signaling and Cell Toxicity upon AAV-Mediated Gene Transfer in hiPSC-Derived CNS Models

Helena Costa Verdera[1], Monah Abou Alezz[1], Vasco Meneghini[1], Elisabeth Mangiameli[1], Inderpal Singh[2], Klaudia Kuranda[2], Ivan Merelli[1], Giuseppe Ronzitti[3], Angela Gritti[1], Federico Mingozzi[2], Anna Kajaste-Rudnitski[1]

[1]SR-TIGET, Milan, Italy,[2]Spark Therapeutics, Philadelphia, PA,[3]GENETHON, Evry, France

Gene therapy with adeno-associated viral (AAV) vectors is being investigated as a promising treatment option for genetic neurodegenerative diseases for which there is currently no cure. Nonetheless, high AAV vector doses are required for clinical efficacy, in particular when targeting the central nervous system (CNS). Recent reports of lethal adverse events and dorsal-root neuron toxicity associated with high AAV doses in clinical trials and large animal studies have raised great concern regarding dose-dependent AAV toxicity and the underlying mechanism. Links between intrinsic innate immunity, cell toxicity and transduction efficacy are emerging, but the potential involvement of innate antiviral sensing of AAV on host-cell toxicity remains largely unknown. Given the species-specificity of vector tropism and innate signaling, and the lack of studies in a human context, we have exploited human iPSC-derived models to assess vector-host interactions and intrinsic innate sensing of AAV in cells of the CNS, in complex environments including mixed neural-glial cultures and 3D cerebral organoids. Functional studies and genome-wide analysis of transcriptional changes triggered by different AAV serotypes revealed early activation of the DNA damage response (DDR), unfolded protein responses and induction of apoptosis, followed by upregulation of inflammatory and antiviral signaling, both in neurons and glial cell subsets. Innate responses and cellular toxicity were further enhanced in mixed cultures and organoids, analyzed by single-cell RNAseq, as compared to the transduction of the various cell types individually, suggesting an active interplay between the different CNS cell subsets in the establishment of a detrimental inflammatory environment. Finally, we used vectors carrying different promoters and transgenes in order to dissect the contribution of the DDR, transgene expression and transgene sequence respectively on the signaling observed in organoids analyzed by single-cell RNASeq. Together, our studies shed light on the mechanisms leading to AAV sensing and neurotoxicity, informing the development of more effective gene therapy and gene correction strategies.

851 Immunogenicity of SARS-CoV-2 DNA Vaccine Candidates Formulated with the Fusion-Associated Small Transmembrane Protein Proteolipid Vehicle Delivery System

DNA vaccines have had limited success in the clinic despite decades of research and development, owing primarily to challenges in delivery. Here we report the generation of DNA vaccine candidates against SARS-CoV-2 utilizing an intracellular nucleic acid delivery platform, FAST-PLV, where plasmid DNA is encapsulated in proteolipid vehicles formulated with a fusion-associated small transmembrane protein and well-tolerated lipids utilizing a scalable microfluidic approach. Selected SARS-CoV2 vaccine candidates comprising full-length SARS-CoV-2 Spike protein combined with two genetic adjuvants (CpG motifs, RIG-I agonist, termed NP-S) elicited potent neutralizing antibody responses in mice and non-human primates at low (sub-milligram) doses indistinguishable from an approved mRNA vaccine. A plasmid DNA vaccine candidate encoding full length Spike protein, NP-S, stimulated significant spike-specific T cell responses including functional cytotoxic T lymphocyte responses. A single dose of NP-S protected hamsters from morbidity following SARS-CoV-2 challenge. The FAST-PLV vaccine platform enables efficient intracellular delivery of DNA payloads and is ideally suited for the development of fridge-stable genetic vaccines against emerging infections.

852 Gene Therapy Approach for Hereditary Spastic Paraplegia Type 52 (SPG52)

[1]Department of Biochemistry and Molecular Biology, Universitat Autònoma de Barcelona, Bellaterra, Spain,[2]Research Group on Gene Therapy at Nervous System, Vall d'Hebron Institut de Recerca (VHIR), Barcelona, Spain,[3]Institut de Neurociències (INc), Universitat Autònoma de Barcelona, Bellaterra, Spain,[4]Department of Pathology and Experimental Therapeutics, Hospital Universitari Bellvitge-IDIBELL, Hospitalet de Llobregat, Spain,[5]Institute of Biomedicine (IBUB), Universitat de Barcelona, Barcelona, Spain,[6]Ciberned, ISCIII, Madrid, Spain,[7]Department of Molecular and Translational Medicine, Università degli Studi di Brescia, Brescia, Italy,[8]Viral Vector Production Unit (UPV), Bellaterra, Spain,[9]Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain

Hereditary spastic paraplegia type 52 (SPG52) is an ultra-rare inherited neurological disorder characterized by lower limb spasticity, weakness, global developmental delay, intellectual disability, and seizures. SPG52 is caused by a biallelic mutation in AP4s1 gene, which encodes a subunit of the adaptor protein complex 4 (AP-4). Mutations in any of its 4 subunits result in complex destabilization and degradation of all subunits, leading to a shared pathophysiology and symptomatology. The function of AP-4 within the cell, although unclear, it is believed to play a key role in autophagosome generation. Currently, this disease does not have a cure nor treatment. We believe that gene therapy targeted to restore AP4s1 expression is a rational therapeutic approach to ameliorate the disease phenotype. Thus, we have generated, characterized, and successfully treated patient-derived fibroblasts with viral vectors carrying a correct copy of the AP4s1 gene. This treatment has not only restored the expression of this specific subunit but has enabled complex expression restoration. To further study the effects of our gene therapy approach in a disease relevant cell type, we have developed and characterized iPSC-derived cortical neurons from patient's samples, which display autophagy alterations. In parallel to our *in vitro* studies, we have developed the first rodent animal model of SPG52. This animal model is a knock-out (KO) mouse generated using the CRISPR-Cas technology targeted to abolish AP4s1 expression in a C57Bl6 strain. To characterize the animal model, cognitive and physical skills batteries have been performed. KO mice show decreased motor coordination as well as muscle strength by grip strength, inverted grid, RotaRod and clasping tests. These KO animals, based on their performance doing the Open Field and Morris Water Maze tests, also display impaired memory while having a regular exploratory behavior with no signs of anxiety. Neuroanatomical changes described in patients, such as the thinning of the Corpus Callosum, have been observed by magnetic resonance imaging and confirmed by histology. In the present, we are treating AP4s1 KO animals systemically with *in vitro* validated neurotropic AAV vector carrying a correct copy of the AP4s1 gene at different ages and assessing phenotype rescue with the battery of cognitive and physical skills tests. The generation of the hiPSC model together with the establishment of this newly generated mouse model, with a phenotype that resembles the human pathology, will be crucial to elucidate SPG52 pathogenesis and to validate our gene therapy approach, key milestones on the road to a successful treatment for SPG52.

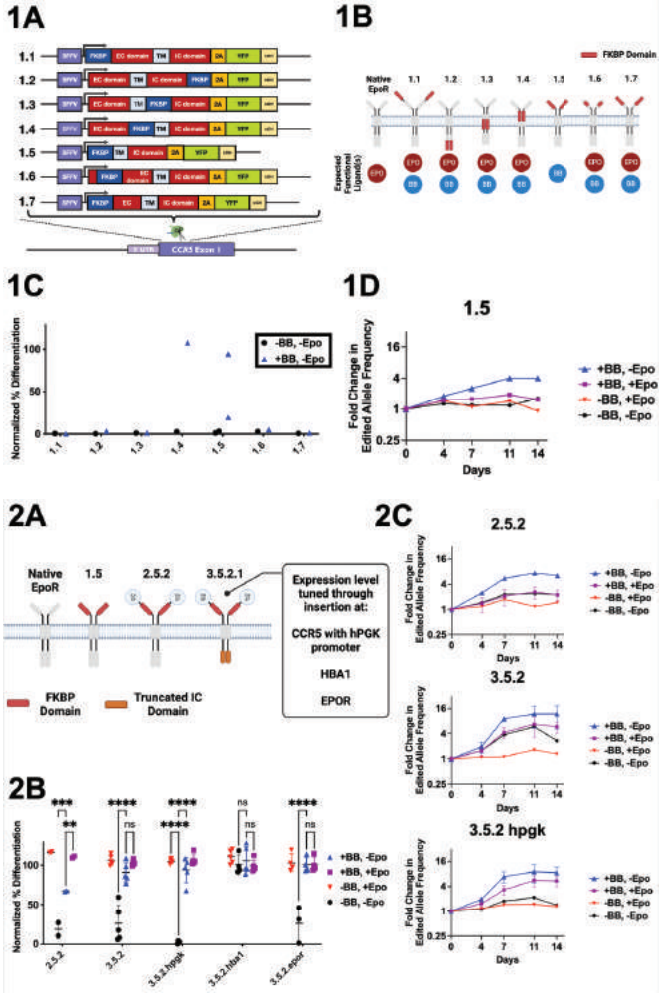
853 Engineering Inducible Signaling Receptors to Increase Erythropoietic Output from Genome-Edited Hematopoietic Stem Cells

Aadit P. Shah[1], Kiran Majeti[2], Sofia Luna[1], Matthew H. Porteus[1], Kyle Cromer[3]

[1]Stanford University School of Medicine, Stanford, CA,[2]Stanford University, Stanford, CA,[3]UCSF, San Francisco, CA

Introduction: Cell and gene therapies (CGTs) are classically limited by editing and delivery efficiencies. However, for hematopoietic stem cell (HSC) therapy, differentiation of the edited stem cell population toward the disease-relevant lineage also has a great bearing on the degree of phenotypic effect. While some diseases exert a selective advantage for genetically modified cells based on the underlying disease pathophysiology, many do not. Although we understand the pathways that define such lineage choices, directly dosing with signaling receptor ligands would not confer selective enrichment of edited cells. Moreover, supra-physiologic dosing with such factors may have deleterious effects on the homeostatic balance of stem cell differentiation. Thus, we designed a system to selectively influence edited cell fate without acting on the broader HSC compartment. Here, we present a set of chimeric, synthetic receptors that enrich edited cell populations towards the erythroid lineage via a non-immunogenic, non-toxic small molecule (SM). **Methods:** In vitro editing was performed using Cas9 protein complexed with the desired gRNA introduced via electroporation and an AAV6 DNA repair template that could be integrated via HDR. Editing was conducted in primary human CD34+ HSCs. Differentiation was determined by flow cytometry assessment of red blood cell (RBC) surface markers. Allele frequency of the edited population during differentiation was determined via droplet digital PCR. **Results:** We hypothesized that inducible dimerization domains currently in the clinic might be paired with EPOR in order to place downstream signaling under the control of a bioavailable SM we refer to as "BB". To test this, we designed a series of FKBP-EPOR chimeras (Fig 1a,b) that are able to yield BB-induced erythroid differentiation (Fig 1c,d). We refer to these constructs as RBCellDrives. We then optimized the design of the RBCellDrive via a) addition of a highly efficient secretory signal peptide; b) inclusion of a naturally occurring intracellular domain truncation with enhanced erythropoietic capacity; and c) insertion with different promoters and at different loci to observe the possible range of expression levels and kinetics (Fig 2a). Through construct optimization, the potency and fidelity of RBC differentiation under BB stimulus ultimately matched or exceeded the ability of EPO (Fig 2b). This was further evidenced by the frequency of edited cells increasing dramatically over the course of RBC differentiation in a BB-dependent manner (Fig 2c). **Conclusions:** We demonstrate the development of synthetic receptors—RBCellDrives—that inducibly mimic the EPOR signaling cascade with high fidelity while obviating dependence on EPO for erythropoiesis. In sum, this could allow clinicians to non-invasively boost the production of clinically meaningful RBCs post-

transplantation. Our work, therefore, has the potential to dramatically improve the efficacy of CGTs and has created novel tools that can be used to better understand fundamental stem cell biology.



854 Use of Precision-Cut Lung Slices to Evaluate Lung Gene Therapy Vectors

Brenna Stevens[1], Madison Hughes[1], Jeff Caswell[1], Khalil Karimi[1], Bernard Thebaud[2], Yanlong Pei[1], Sarah Wootton[1]

[1]University of Guelph, Guelph, ON, Canada,[2]Ottawa Hospital Research Institute, Ottawa, ON

Cystic fibrosis (CF) is the most common monogenic fatal genetic disorder in North America, with a prevalence of around 1 in 2500 people. CF is caused by a diverse range of mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene that lead to systemic disease, with the most fatal pathology occurring in the lung. Gene therapy offers a promising alternative to current treatments as it would work for all CF patients, regardless of mutations. The primary target for gene therapy would be the lung. To ensure the most relevant gene therapy vectors are selected, precision-cut lung slices (PCLS) can be used as an early model to screen candidates. PCLS retain the cellular architecture, microenvironment, and variety of cells of the lungs. **Objective**: The objective of this work was to determine if PCLS transduction can accurately predict *in vivo* transduction results. **Methods**: In this work, the gene therapy vectors Adeno-associated virus (AAV) (serotype AAV6.2FF and AAV9) and lentivirus carrying either green fluorescent protein (GFP) or alkaline phosphatase (AP) as the reporter gene were used to transduce PCLS generated from mice, ferret, sheep, and pigs. Using microscopy and flow cytometry, GFP expression was measured. Using a visual stain and activity assay, AP expression was measured. Animals were also administered the same vectors intranasally, and GFP or AP expression was measured. **Results**: Mouse PCLS showed much higher transduction with AAV6.2FF-GFP than AAV9-GFP via microscopy. This was consistent with *in vivo* transduction results, where flow cytometry demonstrated AAV9-GFP only transduced 25% of the target lung cell population, whereas AAV6.2FF-GFP transduced 65%. In sheep PCLS, AAV6.2FF also outperformed AAV9 in GFP expression. *In vivo*, AAV6.2FF trended towards higher AP expression in mouse lung than AAV9. This higher AP expression was also demonstrated on pig PCLS using the AP stain. Ferret PCLS and lentiviral results are pending. **Conclusion**: PCLS results closely predicted *in vivo* results, and will provide a valuable model on which to screen lung gene therapy vector candidates.

855 Developing an AAV Affinity Chromatography Step

Kelley Kearns

Avitide LLC, a Repligen Company, Lebanon, NH

Cost reduction remains a challenge for downstream processing of recombinant adeno-associated viruses (rAAV). The current work focuses on improvement in recovery through optimization of the elution conditions for the affinity capture step using the commercially available AVIPure® AAV9 resin and an early prototype AVIPure® AAV5 resin. The effect of elution pH, conductivity, type of salt, and additives are demonstrated using a design of experiments (DoE) approach. Such experiments can greatly improve the yield of the chromatography step, while also enabling elution at a higher pH to alleviate concerns regarding viral stability.

856 Silicon Nanoneedle-Mediated Cargo Delivery for Cell Engineering

Abtin Tondar, Eldon Thomas Chou, Lauren Nicole Goetsch, Thomas Masterson, Jake Lesnik

Mekonos, San Francisco, CA

Techniques to introduce foreign molecules or materials into living cells are crucial and potentially rate-limiting processes for cell engineering. Innate cellular functions can be artificially manipulated and reprogrammed by introducing biomolecules such as DNA, RNA, and proteins into the cytosol or nucleus. This process of introducing exogenous cargo into living cells is called intracellular delivery. One popular type of cargo for intracellular delivery is CRISPR gene editing technology, which typically requires delivery of two main components: a guide RNA targeting a specific genomic locus and an RNA-guided endonuclease, such as Cas9, that creates site-specific double-stranded DNA breaks (DSBs) and enables genomic modifications. For certain genome editing applications (i.e. knock-ins), a template plasmid, to facilitate homology-directed repair (HDR), is also required to be delivered into target cells. A big barrier to intracellular delivery

is crossing the cell membrane. Traditionally, viral vectors and electroporation tools have been used to deliver foreign biomolecules into cells. However, both viral vectors and electroporation have limitations and are not optimal for achieving high levels of intracellular delivery while simultaneously maintaining cell viability and functions. As new solutions, microfluidic and nanoneedle approaches show exceptional potential for addressing these unsolved cell engineering obstacles. In this study, we show that Mekonos' silicon nanoneedle-based delivery platform demonstrates unique capabilities for high-efficiency cargo delivery, including CRISPR/Cas9, while maintaining cell viability for cell engineering.

857 Plasmid Impurity Sizing of the *nptII* Kanamycin Resistance Gene in Recombinant Adeno-Associated Virus by Droplet Digital Polymerase Chain Reaction

Sabine Geiger, Felicia Thoennissen, Marina Magerl, Sophie Beer, Paul Zanotti, Sonya M. Schermann, Markus Hörer

Ascend GCTx, Martinsried, Germany

Introduction: Recombinant adeno-associated virus (rAAV)-encapsidated plasmid impurities are an undesirable byproduct of vector manufacturing consisting of heterogeneous (non-vector genome) fragments of DNA arising from the production plasmids. Regulatory authorities require thorough quantification of DNA impurities, but current qPCR methods used to detect impurities are based on quantification of small fragments of the impurity species being quantified. Therefore, these methods provide very limited information on the size distribution of mispackaged DNA species. Horizontal gene transfer of manufacturing plasmid-derived resistance genes is a potential risk when they are packaged as full-length genes. However, this risk may not be identified by currently available analytical methods. Here, we describe a novel method for assessing the size profile of plasmid-derived antibiotic resistance gene impurities in rAAV products. **Method:** A droplet digital PCR (ddPCR) assay was developed to assess kanamycin resistance gene (*nptII*) fragment sizes using four sizes ranging from 99 bp to 795 bp. To measure smaller fragments up to 495 bp in length, a singleplex ddPCR method was used with two primers and one probe. Two duplex ddPCR approaches were used to analyze the full-length gene. The first approach used two primer-probe sets with different fluorophores positioned 795 bp apart so that droplets positive for both fluorophores indicate full-length *nptII* gene sequences. However, this approach carries the risk of overestimating full-length DNA species if two smaller *nptII* gene fragments are co-packaged in the same rAAV capsid, creating double-positive droplets. To reduce false positives, a second approach was developed using two primer-probe sets with two different fluorophores spanning approximately 400 bp fragments at each side of the gene, minimizing the risk of false-positive full-length results (Figure 1). Acceptance criteria for the assay included recovery of >90% of a linearized plasmid control for all fragments analyzed, confirmation of dilutional linearity for plasmid controls and samples, and coefficients of variation <15% for replicate measurements. **Results:** Four large-scale rAAV batches using three different expression cassettes were analyzed for *nptII* impurities using this method. Across batches, the packaging frequency of impurities correlated inversely with fragment length, consistent with long-read next-generation sequencing data. Additionally, batches produced with the same manufacturing platform had consistent size profiles, regardless of the expression cassette. **Conclusions:** The method described here meets requirements for analysis of the size profile of packaged kanamycin resistance gene impurities. Furthermore, the assay enables the assessment of the effects of different biological starting materials and process parameters on the *nptII* impurity size profile. The data generated from this method can form part of a comprehensive assessment of the potential risk from packaged plasmid impurities.

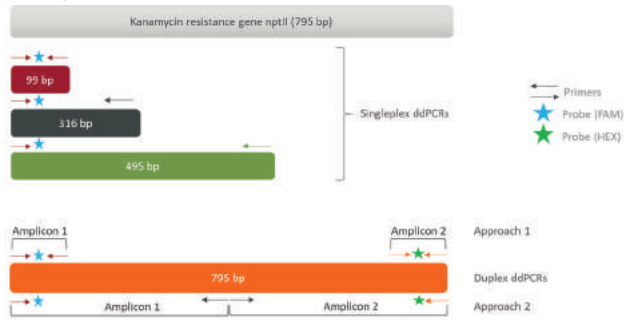


Figure 1. Schematic representation of the assay principle of singleplex and duplex ddPCRs for *nptII*.

858 High-Throughput Pooled Screen of CAR Library Identifies Essential Signaling Features of CAR-T Cells That Resist Immunosuppression

Taeyoon Kyung, Joshua Mace, Jai Raman, Siqi Zhao, Srijani Sridhar, Olga Allen, Kevin Lema, Soon Gang Choi, Lauren Baugh, Sanjiv Shah, Narendra Maheshri, Shawdee Eshghi

Ginkgo Bioworks, Boston, MA

While T cells engineered with canonical chimeric antigen receptor (CAR) designs achieved clinical success in hematological cancer indications, they have shown limited efficacy against solid tumors due to lack of persistence and susceptibility to various immunosuppressive factors in the tumor microenvironment (TME). Systematic discovery of CAR architectures that elicit enhanced T cell functional phenotypes under immunosuppressive environments has been challenging due to technical constraints in high-throughput screening and scaling. Here, we generated a lentiviral CAR intracellular domain (ICD) library composed of 10,000 different 2nd generation CAR designs with individual DNA barcodes in both low and high affinity ROR1 scFv binders and screened for T cell persistence in a chronic stimulation model in a pooled manner. We found unique ICD hits across different binders that outperformed canonical CAR ICDs, which were subsequently validated via an arrayed screen. In order to identify CAR ICDs that potentially resist exhaustion and TME suppression, we screened individual ICD hits in the presence of TGFβ and adenosine against 3-D spheroids in a hypoxic environment. Functional characterization data sets including cytotoxicity, cytokine profiles, and transcriptomics allowed us to comprehend essential signaling components of CAR that could resist a variety of immunosuppressive factors and maintain memory phenotype of T cells for a prolonged period. We believe our approach is readily applicable to identifying signaling

modules driving favorable phenotypes of diverse immune cell types against solid tumors. With the growing interest of utilizing non-conventional T cell subsets, such as γδ T or NKT cells, NK cells, and macrophages as platforms for cell therapy, our CAR library and high-throughput screening platform will facilitate discovering optimized architectures of CAR molecules that could benefit patients with diverse indications in the clinic. Additionally, our platform is compatible with engineering other aspects of CARs including extracellular domains and armoring features of immune cells, such as decoy or switch receptors, that could further assist bypassing TME suppression.

859 Multiplexed Optimization of Serotype, Regulatory Elements and AAV Genome in a Large Animal Model of Heart Failure

Alex Araki, Martin Borch Jensen, Chase Bowman, Chris Carrico, Linda Chio, Atray Dixit, Ian Driver, Daniel Fuentes, Vinay Kartha, Akela Kuwahara, Carmen Le, Francisco LePort, Hikaru Miyazaki, Wyatt Morgan, Dimitry Popov, Frank Sachse, Chris Towne
Gordian Biotechnology, South San Francisco, CA

Gene therapy has had remarkable success in treating rare, monogenic diseases. Realizing this potential for diseases without a clear genetic cause will rely on new methods for identifying optimal molecular targets with demonstrated efficacy. Heart failure is a complex genetic disease that involves the interplay of different cell types and contributions from the systemic environment, meaning that therapeutic efficacy is ultimately only testable in vivo. To increase the scale at which targets can be validated *in vivo*, we previously developed and validated a screening platform where many AAV gene therapies are delivered simultaneously, in a single animal, using single-cell genomics as a phenotypic readout for the therapeutic efficacy of each candidate. In order to apply our platform to heart failure, we required the development of a delivery modality, such as AAVs, capable of cell-type specificity and high transgene expression in the most relevant model, the porcine aortic banding model. Seventeen AAV serotypes were pooled and injected into two mice at doses of 3E10 vg/serotype and 1E11 vg/serotype. After procuring the heart tissue, isolating cardiomyocytes, and running through 10x genomic single-cell workflow, we were able to sequence and process data with readouts of serotype internalized into single-cells. This allowed us to identify several top AAV serotypes: AAVMYO, AAV9, and AAV1 that were validated in individual mice with histological and flow cytometry readouts. Additionally, we tested the top promoters that were identified using a similar single-cell RNA barcode screen of 47 unique regulatory element combinations. We used this data to inform generation of a library for the porcine aortic banding model of heart failure. Seven unique constructs comprising multiple serotypes, regulatory elements, and both single- and double-stranded AAV genomes, were delivered two weeks following aortic banding at a total dose of 2E14 vg. Four weeks later, histology and single cell sequencing allowed us to identify the optimal serotype, regulatory elements and AAV genome configuration in this large animal model. Having optimized gene delivery in the most relevant model of heart failure, our next steps are to use our platform for multiplexed screening of hundreds of therapeutic candidates for this non-monogenetic, complex disease.

860 Local Delivery of Vectorized Therapeutics Targeting a Pro-Inflammatory Cytokine Effectively Reduces Disease Severity in a Mouse Model of Non-Infectious Uveitis

Jessica Gumerson, Mi Shi, Wei-Hua Lee, Justin Glenn, Xu Wang, Olivier F. Danos, Ye Liu, Joseph T. Bruder, Brendan Lilley
Regenxbio, Rockville, MD

Uveitis comprises a heterogenous group of inflammatory intraocular diseases that can result in vision loss. Non-infectious uveitis (NIU) of the posterior segment of the eye can be difficult to treat, requiring long-term systemic immunosuppression with significant side effects. Here, we test the hypothesis that local expression of cytokine inhibitors in the eye, mediated by AAV delivery, can suppress inflammation as a potential treatment for uveitis. Inhibitors of the pro-inflammatory cytokine TNF-α, a validated target for treating uveitis, were evaluated in multiple formats including modified soluble receptors and antibodies. Vector expression was initially screened *in vitro* via transfection in 293T and ARPE-19 cells. Two additional cell-based assays were used to test inhibitory activity across multiple species. Inhibitors demonstrating high expression and bioactivity were then produced as AAV8 vectors for further testing *in vivo*. The classical B10.RIII Experimental Autoimmune Uveitis (EAU) mouse model was used to test whether local expression of anti-TNF-α factors was sufficient to prevent intraocular inflammation. Three weeks after subretinal injection of AAV, EAU was induced. Ocular function and disease progression were assessed at multiple timepoints using optical coherence tomography, fundus imaging, and optokinetic tracking. Following final *in vivo* assessments, eyes were collected and examined further for EAU histopathology or transgene expression. Clinical scores were assigned using established criteria for evaluation of fundus and histopathology images. Control EAU animals receiving either vehicle or a non-specific transgene demonstrated a robust increase in ocular inflammation as indicated by high clinical scores and near complete absence of visual acuity. In animals expressing potent TNF-α inhibitors, we observed a dose-dependent reduction in the severity of inflammation and improvement in visual acuity. These data suggest that local inhibition of TNF-α via AAV-mediated transfer of an inhibitor in the eye can successfully limit inflammation associated with uveitis and support further pre-clinical development of a vectorized therapeutic approach to the treatment of non-infectious uveitis.

861 Trivalent miRNA Constructs Targeting C9ORF72 for the Treatment of Amyotrophic Lateral Sclerosis

Tran Doan Ngoc Tran-Prasad
Gene therapy, AGTC (Applied Genetic Technologies Corporation), Cambridge, MA

Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) are severe neurodegenerative diseases with no effective treatment. ALS is a fatal neurodegenerative disease characterized clinically by progressive paralysis leading to death from respiratory failure, typically within three to five years of symptom onset. A hexanucleotide GGGGCC repeat expansion in the C9ORF72 gene is the most frequent genetic cause of both ALS and FTD in Europe and North

America. The mechanisms of C9ORF72 toxicity in neurodegeneration is suggested by loss of function of C9ORF72 protein, and toxic gain of function from sense and antisense C9ORF72 repeat RNA or from dipeptide repeat proteins (DPRs). In this study, we designed trivalent constructs comprised of C9ORF72 gene supplementation and miRNA cassettes to knockdown C9ORF72 sense and antisense transcripts. We designed 86 miRNAs that target both sense and antisense C9ORF72 transcripts. To screen and select the top sense and antisense microRNA candidates that cause the C9ORF72 transcript knockdown, we utilized the dual luciferase reporter assay after co-transfecting miRNA plasmids and reporter plasmid into HEK293T cells. Based on reporter screening results, we performed bioinformatics analyses to predict top 30 miRNA target sites, binding potential among species, and identify off-targets. Next, we confirmed the top 25 miRNA candidates' performance in vitro using RT-qPCR analysis on the endogenous C9ORF72 by transfecting the miRNA plasmids into HEK293T cells. The top 10 best performing miRNA were chosen to build the trivalent constructs. Each construct contains sense and antisense miRNA under pol III promoter and a C9ORF72 gene that is resistant to the miRNA (codon-modified non-self-silencing C9ORF72). We utilized the luciferase assay to confirm the miRNA knockdown effects and western blotting to verify the expression of C9ORF72 protein from the miRNA resistant constructs. We identified 19 miRNAs targeting a variety of loci along C9ORF72 with at least 70% knockdown using luciferase reporter assay. Bioinformatics revealed the top 5 sense miRNAs and 1 antisense miRNA that have preferred target sites on canonical C9ORF72 gene with least off-target predictions. RT-qPCR showed the top miRNAs reduced endogenous C9ORF72 mRNA levels in HEK293T cells by at least 50%. Trivalent construct performance in the reporter assay showed consistent knockdown effects of the miRNA. Western blot analysis verified the expression of C9ORF72 from the trivalent miRNA resistant constructs. In this study, we report for the first time the generation of trivalent constructs containing miRNA to silence endogenous C9ORF72 and augmenting C9ORF72 levels using miRNA resistant constructs, making them a potential therapeutic approach to target ALS. The next steps will be investigating the effect of AAV containing the trivalent constructs in human-derived iPSC neurons, transgenic C9ORF72 mouse model and non-human primate to facilitate the effective treatment for ALS and FTD patients.

862 A Novel, Highly Efficient Epigenome-Editing System Based on an All-in-One Adeno-Associated Vector Delivery Platform: Preclinical Proof-of-Concept and *In Vivo* Validation

Boris Kantor[1], Bernadette Odonovan[2], Joseph Rittiner[1], Ornit Chiba-Falek[3]

[1]Neurobiology, Duke University- School of Medicine, Durham, NC,[2]Neurology, Duke University- School of Medicine, Durham, NC,[3]Neurology, Duke University, Durham, NC

Clustered Regularly Interspaced Palindromic Repeats (CRISPR)/dCas9-based epigenetic editing is an emerging field in developing safe and effective gene engineering tools. The system consists mainly of a single guide RNA (sgRNA) and a deactivated-Cas9 nuclease (dCas9). By fusing a transcriptional repressor domain to the CRISPR/dCas9 nuclease, transcriptional repression complexes are recruited to silence the specific gene target sites safely and effectively. Adeno-associated vector (AAV) is a platform-of-choice for the delivery of therapeutic cargoes; nevertheless, its small packaging capacity is mainly not suitable to be utilized for the efficient delivery of large cargoes, such as CRISPR/dCas9-effector systems. To circumvent this limitation, most AAV -based CRISPR/Cas tools delivered separately from two viral cassettes. However, this approach requires higher viral payloads and usually is less efficient. Here, we describe a compact CRISPR/dCas9 system packaged within a single AAV vector. The system based on small transcription repression domain (TRD) derived from MeCP2 repressor, fused with KRAB repressor. We demonstrated that the developed system can be efficiently packaged into AAV particles. Using this system, we were able to induce a robust and sustained editing in vitro and in animal models of neurological diseases in vivo. We believe that the novel AAV-based platform could broaden the CRISPR/Cas9 toolsets for efficient epigenome-based perturbations in the therapeutic settings.

863 Low-Dose Binary Oncolytic/Helper-Dependent Adenovirus (CAdVEC) Promotes Anti-Tumor Activity in Preclinical and Clinical Studies

Daniel Wang[1], Caroline Porter[1], Bora Lim[1], Amanda Rosewell Shaw[1], Catherine Robertson[1], Mae Woods[1], Ya Xu[1], Greyson Biegert[1], Daisuke Morita[2], Tao Wang[1], Bambi Grilley[1], Helen E. Heslop[1], Malcolm K. Brenner[1], Masataka Suzuki[1]

[1]Baylor College of Medicine, Houston, TX,[2]Shinshu University, Matsumoto, Nagano, Japan

Administration of oncolytic adenoviruses may help control some human tumors, but their limited potency means toxic or technically unfeasible doses may be required for maximal efficacy. Here we show that a binary oncolytic/helper-dependent adenovirus (CAdVEC) that both lyses tumor cells and locally expresses the pro-inflammatory cytokine IL-12 and PD-L1 checkpoint blocking antibody has high potency and efficacy in a range of humanized mouse models, including breast and pancreatic cancers. Based on these preclinical studies, we treated 4 patients with relapsed, resistant head and neck squamous cell cancer or breast adenocarcinoma (NCT03740256) with a single intratumoral injection of a low-dose of CAdVEC, representing a quantity of oncolytic adenovirus that is more than 100-fold lower than the starting dose of previous oncolytic adenovirus trials. While low-dose CAdVEC caused no significant hepatic transaminitis or systemic cytokine elevation, it nonetheless induced proinflammatory repolarization of the tumor microenvironment with increased infiltration of natural killer cells and CD8 T cells, replicating the effects observed in our humanized mouse models. A single intratumoral administration of low-dose CAdVEC was associated with both loco-regional and abscopal effects on distant metastases, and with subsequent administration of systemic immune checkpoint inhibitor, induced long-term anti-tumor effects, including one complete and two partial responses in patients. In both pre-clinical and clinical studies, a binary combination of oncolytic and immunostimulatory adenoviral vectors (CAdVEC) is safe and sufficiently potent to induce significant tumor control through oncolysis and immune repolarization, even at

extremely low doses. We are now investigating the mechanism(s) by which such low-dose CAdVEC led to durable anti-tumor responses in patients.

864 A Dual-Fluorescence Assay for Gene Delivery Vehicle Screening in Macrophages with an Inflammation-Inducible Reporter Construct

Alexis Ivy[1], Mary S. Jia[2], Christopher E. Nelson[3]

[1]Biomedical Engineering, University of Arkansas Biomedical Engineering, Fayetteville, AR,[2]University of Arkansas, Fayetteville, Fayetteville, AR,[3]University of Arkansas, Fayetteville, AR

Macrophages are necessary for the immune system to respond appropriately to outside invaders. Macrophages are complex and can change phenotype according to specific activation pathways. This includes an array of activation states from homeostasis to defense. When cellular pathways that affect macrophage plasticity are dysregulated in disease, macrophages can remain in their inflammatory state, and drive chronic inflammation. The role of macrophage plasticity in chronic inflammation is an interesting target for therapeutic development in chronic inflammation. One issue with targeting macrophages for drug development is their innate response to outside invaders, which makes delivery using viral or non-viral vehicles difficult and can cause activation of macrophages. Macrophages have been targeted in the past for cancer cell therapy where the macrophages needed to be activated to attack the cancerous cells. In an environment where the goal is to diminish inflammation, a delivery vehicle that both ensures efficient delivery and mitigates inflammatory response. We propose the development of an inflammatory reporter plasmid that expresses mCherry in an inflammatory environment. When activated, macrophages produce the inflammatory cytokine TNF-α which in turns activates NF-kB, a potent transcription factor. The inflammatory reporter plasmid utilizes mCherry under a previously defined inflammatory promoter that recruits NF-kB regulatory elements to a minimal CMV promoter that acts as the transcription start site. The reporter was then stably integrated into RAW264.7 mouse macrophages to test different viral and non-viral delivery vehicles. Various serotypes of the viral vectors Adenovirus (AdV), Adeno-associated virus (AAV), and lentivirus were used to deliver green fluorescent protein (GFP) to the RAW264.7 inflammatory reporter cell line. Using this dual-reporter system, we can determine which delivery vehicles provide both efficient delivery and minimize the inflammatory response by macrophages. Number of cells expressing mCherry and GFP will be quantified using flow cytometry and the output will be a matrix where GFP+/mCherry- equates to efficient delivery and minimal/no inflammation. Development of this dual-reporter assay will establish an effective delivery method that can be utilized as a starting point for a macrophage therapeutic platform, the basis for high-throughput screening, and manipulation of macrophages *in vivo*.

866 Anti-PD-1 Chimeric Antigen Receptor T Cells Efficiently Target SIV-Infected CD4+ T Cells in Germinal Centers of Rhesus Macaques

Karsten Eichholz[1], Yoshinori Fukazawa[2], Christopher W. Peterson[1], Francoise Haeseleer[1], Manuel Medina[2], Shelby Hoffmeister[2], Derick Duell[2], Benjamin Varco-Merth[2], Sandra Dross[3], Haesun Park[2], Caralyn Labriola[2], Michael Axthelm[2], Robert Murane[4], Jeremy Smedley[2], Lei Jin[1], Rust Blake[1], Deborah Fuller[5], Hans-Peter Kiem[6], Louis J. Picker[7], Afam Okoye[2], Larry Corey[1]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]Vaccine and Gene Therapy Institute, Beaverton, OR,[3]7Department of Microbiology, Seattle, WA,[4]Washington National Primate Research Center, Seattle, WA,[5]Department of Microbiology, Seattle, WA,[6]Fred Hutch, Seattle, WA,[7]Oregon Health & Science University, Beaverton, OR

Background: Programmed cell death protein 1 (PD-1) is an immune checkpoint marker commonly expressed on memory T cells and enriched in latently-infected CD4+ T cells containing replication-competent human immune deficiency virus 1 (HIV) provirus in people with HIV on antiretroviral therapy (ART). **Methods:** We engineered novel chimeric antigen receptor (CAR) T cells that can efficiently kill PD-1 expressing cells *in vitro* and *in vivo* to assess the impact of PD-1 depletion on viral reservoirs and rebound dynamics in simian immunodeficiency virus (SIV) mac239-infected rhesus macaques (RMs). Adoptive transfer experiments of anti-PD-1 CAR T cells were done in 2 SIV naïve and 4 SIV-infected RMs on ART. **Results:** In 3 of 6 RMs, one SIV naïve and 2 SIV+ RMs, anti-PD-1 CAR T cells expanded efficiently and persisted for up to 100 days concomitant with the depletion of PD-1+ memory T cells in blood and tissues, including CD4+ follicular helper T cells (T_{FH}). This depletion of T_{FH} in lymph nodes was also associated with depletion of detectable SIV RNA from the germinal center (GC). However, following ART interruption, there was a marked increase in SIV replication in extrafollicular portions of lymph nodes, a 2-log higher plasma viremia relative to controls and accelerated disease progression, associated with the acute depletion of CD8+ memory T cells after CAR T infusion in SIV+ RMs on ART. **Conclusions:** These data indicate anti-PD-1 CAR T cells can target and deplete PD-1+ T cells *in vivo* including GC T_{FH} cells and eradicate SIV from this immunological sanctuary. Approaches to limit CAR T cell-mediated depletion to PD-1+ CD4+ T cell reservoirs and reduced off target CD8+ memory T cell depletion should be pursued.

867 Potent and Uniform Fetal Hemoglobin Induction via Base Editing

Thiyagaraj Mayuranathan[1], Gregory A. Newby[2], Ruopeng Feng[1], Yu Yao[1], Kalin D. Mayberry[1], Cicera R. Lazzarotto[1], Yichao Li[1], Rachel M. Levine[1], Nikitha Nimmagadda[1], Erin A. D. Dempsey[1], Guolian Kang[3], Shaina N. Porter[4], Phillip A. Doerfler[1], Jingjing Zhang[1], Yoonjeong Jang Jang[1], Jingjing Chen[1], Henry W. Bell[5], Senthil Velan Bhoopalan[1], Akshay Sharma[6], John F. Tisdale[7], Shondra M. Pruett-Miller[4], Yong Chen[1], Shengdar Q. Tsai[1], David R. Liu[2], Mitchell J. Weiss[1], Jonathan S. Yen[1]

Elevated fetal hemoglobin (HbF, α2γ2) in red blood cells (RBCs) can ameliorate sickle cell disease and β-thalassemia. Gene editing strategies are a promising approach to manipulate the regulatory genetic elements and induce therapeutic levels of HbF. Base editors have been used to generate naturally occurring hereditary persistence of fetal hemoglobin (HPFH). Moreover, HPFH variants that create de novo binding motifs for erythroid transcriptional activators at the γ-globin promoter can be introduced with base editors but not with Cas9 nuclease mediated non homologous end joining. However, the best gene editing strategies for therapeutic HbF induction are not known.We compared Cas9 nuclease and base editing strategies for HbF induction by modifying $CD34^+$ hematopoietic stem and progenitor cells (HSPCs). Specifically, we used Cas9 nuclease to disrupt an erythroid enhancer in the *BCL11A* gene or a BCL11A binding motif in the γ-globin promoter. Alternatively, we used adenine base editors to create base pair substitutions at γ-globin promoter positions -198, -175, and -113, thereby generating de-novo binding motifs for KLF1, TAL1, and GATA1, respectively. The -175 A>G base edit proved to be the most potent edit.Clonal analysis by analyzing burst forming unit-erythroid (BFU-E) colonies derived from base edited CD34+ cells revealed that -175 A>G base edit in all four γ-globin genes expressed 81±7% HbF compared to 17±11% in unedited controls. HbF induction in BFU-E colonies was lower and more variable with two Cas9 nuclease strategies: 32±19% and 52±13% HbF expression after targeting the γ-globin promoter and *BCL11A* enhancer, respectively. Surprisingly, analysis of specific indels in colonies revealed significant HbF induction with a 13 bp and 4 bp deletion but not with -1, -2, -3 or +1 indels, even though they all disrupted the BCL11A binding motif. In contrast, all high frequency indels targeting the *BCL11A* enhancer disrupted a functionally important GATA1 binding motif and induced HbF similarly, albeit with greater variability than colonies with the -175 A>G base edit.Installing the -175 A>G base edit with the more active ABE8e editor yielded a 1.6-fold improvement in editing efficiency relative to ABE7.10, accompanied by 1.4-fold increase in %HbF induction. In xenotransplant studies with ABE8e using HSPCs isolated from an SCD patient, we achieved on-target input editing of 62% and retained 42±3% after engraftment, resulting in 62±8% HbF expression. After transplantation of $CD34^+$ cells from the same donor that were treated with Cas9 nuclease to disrupt the BCL11A binding motif, 27±5% HbF was achieved with 75±5% editing in engrafted cells. Overall, our data identifies a base editing strategy for potent induction of HbF and demonstrates that diverse indels generated by Cas9 nuclease cause unexpected variation in biological outcomes that can be circumvented by base editing, with important implications for therapeutic gene editing efforts.

868 Multilineage Engraftment of HSCs Derived Anti HIV CAR Cells *In Vivo*

Wenli Mu[1], Hwee Ng[1], Valerie Rezek[1], Mayra A. Carrillo[1], Shallu Tomer[1], Wallace D. Wennerberg[1], Vincent Le[1], Vaibhav Patankar[1], Martin A. Heather[1], Scott G. Kitchen[2], Anjie Zhen[2]

Achieving HIV cure or remission without anti-retroviral therapy (ART) treatment requires the enhancement and persistence of effective antiviral immune responses. Chimeric Antigen Receptor (CAR) T-cells have emerged as a powerful immunotherapy for various forms of cancer and show promise in treating HIV-1 infection. However, persistence, trafficking, and maintenance of function remain major challenges for peripheral CAR-T cell therapy, which results in limited antiviral efficacy in vivo. To overcome those limitations, we created long-lasting anti-HIV responses by modifying autologous Hematopoietic Stem Cells (HSCs) with anti-HIV CAR molecule. In addition, the gene therapy vector expressing this CAR molecule also contains anti-HIV genes, which protects the CAR-expressing immune cells from infection. Our studies in humanized mice and non-human primates (NHPs) have demonstrated that HSCs based CAR therapy could provide life-long engraftment and production of functional CAR-T cells, resulting in significantly reduced viral rebound after ART withdrawal. Interestingly, we observed successful differentiation of multiple hematopoietic lineages expressing CAR molecule, including CAR macrophages and CAR-NK cells that could contain anti-HIV activity and boost functions of CAR-T cells. Importantly, we demonstrated that HSC-derived, multilineage CD4CAR+ cells were able to traffic to and persist in HIV tissue associated reservoir sites, including lymphoid germinal centers, central nervous system tissues, and gastrointestinal tract tissues. To further investigate the antiviral functions of multilineage CAR immune cells, we transduced primary NK cells and Macrophages with improved second generation anti-HIV D1D2CAR-41BB lentivirus used in our previous studies. We found that both CAR-NK and CAR-MQs secrete proinflammatory cytokines and kill HIV+ target cells. To further investigate CAR T and CAR NK cells in vivo, we generated humanized mice using human CD34+ HSCs that were gene modified with D1D2CAR-41BB in NSG-Tg(Hu-IL-15) mice. We observed successful CAR T cells and CAR NK cells differentiation from modified HSCs in NSG-hu-IL-15 mice. After HIV infection, we detected significant increase of activation receptors NK2GD and NKp46 on CAR-NK cells. Importantly, a significant (>6 fold) reduction of viral load in D1D2CAR-HSCs mice were observed as early as two weeks post infection. The early viral suppression may

be contributable to CAR-NK cell activity as most naïve CAR-T cells have not fully differentiated into effector T cells yet. Collectively, our data support that development of multi-armed immunity from CAR engineered HSCs may provide broader and long-term immune surveillance for HIV infection.

869 Persistent Genetic Modification of K562 and Human Hematopoietic Stem and Progenitor Cells Using S/MAR DNA Nanovectors

Patrick Derigs[1,2], Alicia Roig-Merino[3], Julia Denise Peterson[1], Luisa Burger[1], Toros Tasgin[1], Anna Hartley[1], Michael Schmitt[2], Carsten Müller-Tidow[2], Richard P. Harbottle[1]

[1]DNA Vector Lab, German Cancer Research Center, Heidelberg, Germany,[2]Department of Internal Medicine V, University Hospital Heidelberg, Heidelberg, Germany,[3]MaxCyte, Gaithersburg, MD

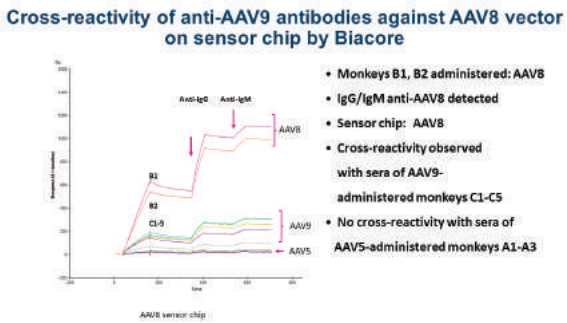
Effective strategies for the persistent genetic modification of hematopoietic stem and progenitor cells (HSPCs) have the potential to revolutionize the treatment of various genetic hematological disorders like severe combined immunodeficiency and Fanconi anemia. For gene delivery into HSPCs recombinant integrating viruses are a potent and widely used tool. However, their random integration into the genome introduces a risk of insertional mutagenesis. Their innate immunogenicity also presents another impediment to clinical application. To achieve the goal of an efficient and safe generation of stably transfected cells of a variety of cell types, we have developed a non-viral DNA vector platform based on Scaffold/Matrix-Associated Regions (S/MAR). The episomal maintenance of S/MAR DNA nanovectors (nS/MAR) eradicates the risk of insertional mutagenesis, providing a major advantage compared to already clinically applied approaches using CRISPR/Cas9 systems or viral vectors. Additionally, with its unlimited capacity, even large therapeutic transgenes or other sophisticated genetic elements can be delivered with nS/MAR. Furthermore, genetic engineering based on n/SMAR with its inherent mitotic stability should minimize costs for the manufacturing of genetically modified HSPCs. In this study, we have evaluated the efficiency and persistence of reporter transgene expression in the widely used hematopoietic K562 cell line and HSPCs using nS/MAR. K562 cells and primary human HSPCs were electroporated with nS/MAR containing the human elongation factor-1 alpha promoter and a fluorescent reporter transgene (dTomato) using the MaxCyte ExPERT® platform. HSPCs were isolated by performing MACS® Cell Separation with CD34 microbeads on 10-year cryopreserved leukapheresis material. 2.5 x 10^6 K562 cells and 1.25 x 10^6 primary human HSPCs were electroporated using the MaxCyte ExPERT GTx®. Transfection efficiency and cell viability were analyzed using flow cytometry. Our study demonstrates the feasibility of using nS/MAR for persistent genetic modification of K562 and HSPCs. K562 cells, which serve as a model for a highly proliferative hematopoietic cell population, can be transfected highly efficiently with our vector system. We demonstrate the generation of stable isogenic transgenic K562 cells which stably express dTomato without selection. These isogenic cells represent an important cell line for assays in the development of new immunotherapeutic approaches. K562 express a variety of different epitopes including CD33 which is an important target in the immunotherapy of acute myeloid leukemia. In contrast to K562, the transfection efficiency of primary human HSPCs was lower, with scope for improvement. However, our results demonstrate the ability of nS/MAR to transfect HSPCs even from poor-quality cryopreserved leukapheresis material. These findings provide a promising first step towards the genetic modification of HSPCs with nS/MAR and their usage in hematopoietic cell transplantation for the treatment of genetic hematological disorders. Further studies are ongoing to determine the optimal conditions for efficient modification of HSPCs including electroporation and expansion protocols.

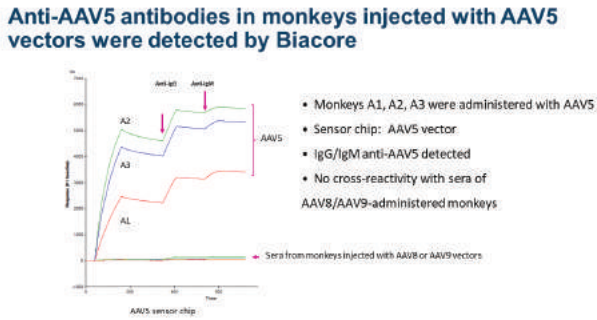
870 Analysis of Cross-Reactivity of Anti-AAV Antibodies Elicited in Cynomolgus Monkeys Administered with AAV5, 8, or 9 Vectors

Yanshan Dai[1], Glen B. Banks[2], Grace Wu[1], Jiin-jia Liaw[1], Nathaniel Collins[1], Paul C. Levesque[3], Sekhar Surapaneni[1], Vibha Jawa[1], Alexander Kozhich[1]

[1]Bristol Myers Squibb Company, Lawrenceville, NJ,[2]BMS, Princeton, NJ,[3]Bristol Myers Squibb, Summit, NJ

In the case of gene therapy delivered by adeno-associated virus (AAV) vectors, therapeutic protein expression may decrease over time. We were interested to test whether the intravenous administration of either AAV5, 8, or 9 in monkeys led to cross-reactive antibodies. The Surface Plasmon Resonance (SPR)-based immunoassay allows for label-free detection, automated operation, rapid analysis in real-time, and high specificity. We developed a Biacore SPR-based total binding antibody (TAb) assay for the direct detection of anti-AAV antibodies in the monkey serum to examine the cross-reactivity of anti-AAV antibodies after administration of AAV5, 8, or 9 vectors. AAV5, 8, and 9 vectors were immobilized onto a CM5 sensor chip surface on Fc2, Fc3, and Fc4, respectively by amine coupling. Fc1 served as a reference. Serum samples then flowed across 4 flow channels, followed by injection of anti-monkey IgG and IgM antibodies to determine isotypes. Cynomolgus monkeys were intravenously administered with AAV5, AAV8, or AAV9 vectors. To evaluate anti-AAV antibody responses after AAV administration, we analyzed neutralizing antibodies (NAb) and TAb against the AAV serotypes in the serum with cell-based NAb assay and Biacore-based TAb assay on 15- and 29 days after administration. While all 10 monkeys developed NAb against administered AAV capsids with a titer of 1:10,000, only 2 monkeys developed cross-reactive NAb against one of the other AAV serotypes with titers of 1:100 and 1:1000, respectively. TAb determined by Biocore-based assay were found to be cross-reactive between antibodies against AAV8 and AAV9, but there was little cross-reactivity between antibodies against AAV5 and AAV8/9 serotypes. Both IgG and IgM TAb on 15- and 29-days post-dosing were detected by Biacore, and antibody profiles determined by Biacore and ELISA platforms were comparable. Taken together, the Biacore-based assessment confirmed the lack of cross-reactivity of anti-AAV5 antibodies to AAV8, 9, or vice versa. The lack of cross-reactive antibodies against an AAV serotype may leave the possibility of re-administration of a different AAV serotype.





871 A Screening Strategy of Synthetic AAVs for Cell Type-Specific Targeting and Precise Gene Therapy

Cenfeng Chu[1], Huifang Zhang[1], Guodong Jia[2], Guisheng Zhong[3]

[1]Shanghai EmayGene Biotech Co. Ltd., Shanghai, China,[2]OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China,[3]ShanghaiTech University, Shanghai, China

The ability to replace or edit genes has the potential to treat many genetic diseases. However, targeting specific cells remains a major challenge since few cell type-specific enhancers or promoters were identified. Here, we present a strategy for selecting adeno-associated virus (AAV) variants that express genes in specific types of tissue cells in vivo. By applying this strategy, we identified AAV variants transducing different types of cochlear cells, including inner and outer hair cells, supporting cells, outer pillar cells, inner border cells, and spiral ganglion neurons with superior efficiency and selectivity. We showed that specific AAV variants enabled precise gene therapy in the Tprn-/- mouse deafness model. Those cell type-specific AAVs would be valuable for functional studies and gene therapies for deafness, and the strategy could be potentially applied to screen specific AAV variants in other tissues.

872 Quantitative, Image-Based Assays for the Functional Evaluation of RNA and Gene Therapies Targeting Muscle Disorders

Beatrice Darimont[1], Oana Lorintiu[2], Cecile Gaston[2], Melanie Flaender[2], Tiphaine Champetier[2], Antoine Martin[2], Giulio Morrozi[2], Eve Duchemin-Pelletier[2], Violaine Chapuis-Perrot[2], Celine Massera[2], Louise Griveau[2], Margaux Papin[2], Caroline Roelants[2], Aurelie Dupont[2], Pauline Poydenot[2], Joanne Young[2], Erwann Ventre[2], Luc Selig[2]

[1]Cytoo, Cambridge, MA,[2]Cytoo, Grenoble, France

Significant advances in RNA and gene therapies have finally enabled the clinical development of targeted therapies for muscle disorders. However, for many programs, clinical trials have been hampered by clinical holds. The lack of suitable cell-based functional assays that can be performed under physiological conditions and can serve as potency assays for product release is a critical challenge for these programs during development. We pioneered MyoScreen™, an *in vitro* R&D platform that enables testing muscle therapies in primary and immortalized patient-derived skeletal muscle cells. Under MyoScreen conditions, myoblasts are differentiated on micropatterned plates resulting in standardized and well-differentiated myotubes. Taking advantage of these properties, we have developed image-based, automated assays that enable the functional evaluation of RNA and gene therapies *in vitro*. The first group of assays monitors the colocalization of proteins within protein complexes that are critical for muscle functions, such as the interaction of dystrophin with other components of the Dystrophin-Glycoprotein Complex. A second group of assays uses Artificial Intelligence (AI)-powered cell profiling to define disease-associated cellular phenotypes in myotubes. Utilizing phenotypical profiles derived by machine learning from myotubes labeled for disease relevant proteins or cellular features, we define a Health-Score™ (% phenotypically healthy cells out of total) that quantifies the ability of therapies to revert disease-associated phenotypes. By imaging proteins that are part of the Dystrophin-Glycoprotein Complex, we demonstrate that these assays reproducibly and robustly monitor the function of dystrophin and assess the activity of restored dystrophin in DMD patients treated with gene and RNA therapies. The same assays can also be used to monitor therapies targeting DM1 where the recruitment of RNA splicing proteins by extended CUG repeats in the DMPK pre-mRNA leads to alternative splicing of dystrophin. Modifying the proteins or cellular features used for imaging enables the adaptation of these assays to other muscle disorders. In addition to their use as potency assays, these assays can predict the response of individual donors to therapies and can be applied for target and lead identification, to characterize mechanisms of action, and for the identification of biomarkers. Moreover, the phenotypical approach of the AI-powered cell profiling offers new opportunities for target and lead identification in neuro-muscular disorders with diverse or complex mechanisms.

873 Polymeric Nanoparticles for *In Utero* Gene Delivery in the Fetal Rhesus Monkey

Anna Y. Lynn[1], Alexandra S. Piotrowski-Daspit[1], David A. Eaton[1], Ryland D. Mortlock[1], Alice F. Tarantal[2], Peter M. Glazer[3], W. Mark Saltzman[4]

[1]Department of Biomedical Engineering, Yale University, New Haven, CT,[2]Department of Pediatrics and California National Primate Research Center, University of California, Davis, Davis, CA,[3]Department of Therapeutic Radiology, Yale University School of Medicine, New Haven, CT,[4]Department of Biomedical Engineering, Yale School of Engineering and Applied Science, New Haven, CT

Introduction: Advances in fetal medicine have dramatically improved the ability to diagnose genetic diseases prenatally. These advances present opportunities to consider treating these disorders early during development. Fetal intervention provides a means to avoid pathology and tissue damage; gain access to privileged anatomical sites and unique stem and progenitor cell populations; and to administer a low dose-to-volume ratio for therapeutic efficacy. In small animal models, polymeric nanoparticles (NPs) have been demonstrated to effectively deliver gene-editing agents to target sites *in utero* [1]. For clinical translation, this technology must be shown to be safe and validated in a large animal such as the rhesus monkey. Here, we investigated biodistribution after polymeric NP delivery into the fetal rhesus monkey under ultrasound guidance. **Methods:** A block co-polymer of poly(amine-co-ester) (PACE) and polyethylene glycol (PEG) polymer was synthesized using enzyme-catalyzed copolymerization as previously described [2]. Poly(lactic-co-glycolic acid) (PLGA) and PACE-PEG NPs encapsulating lipophilic fluorescent DiD dye were formulated by a single-emulsion evaporation method. PACE-PEG NPs encapsulating mRNA for Green Fluorescent Protein (GFP) were formulated by a double-emulsion evaporation method. Time-mated rhesus monkeys were identified as pregnant sonographically then selected for the study. Rhesus fetuses in the early second trimester were transferred using an intraportal approach under ultrasound guidance (100 mg/kg). Fetal tissues were collected post-hysterotomy ~24 hours after DiD NP injection or ~48 hours after GFP NP administration for analysis including whole tissue fluorescent imaging and frozen sections of tissues using fluorescence microscopy. Images were processed in Fiji and the relative fluorescence was calculated using a custom routine coded with MATLAB [3]. **Results:** PLGA NPs were found primarily in the fetal liver, while the PACE-PEG NPs showed a wider tissue biodistribution. **Conclusions:** PLGA and PACE-PEG NPs were successfully and safely distributed after *in utero* delivery via the fetal portal vein. PACE-PEG NPs were found in a range of fetal tissues, which is consistent with the delivery profile seen previously in small animal models. This initial work suggests that polymeric NPs are potential candidates for efficient fetal delivery of therapeutic nucleic acids. Further studies are required to address the potential clinical translation of this innovative technology. **References:** 1. 874 Predictive Potential of Single Deleterious Variations to Infer on AAV2 and AAV2-13 Capsids Viability

Tiziana La Bella[1,2], Bérangère Bertin[1,2], Ante Mihaljevic[1,2], Dylan Serillon[3], Anastasia Barkova[3], Justine Nozi[1,2], Patrice Vidal[1,2], Jean-Philippe Buffet[3], Sandrine Imbeaud[4], Jean-Charles Nault[4,5], Julien Cottineau[3], Jessica Zucman-Rossi[4,6], Giuseppe Ronzitti[1]

[1]GENETHON, Evry, France,[2]Integrare Research Unit UMR_S951, Evry, France,[3]WhiteLab Genomics, Paris, France,[4]Centre de Recherche des Cordeliers, Paris, France,[5]Avicenne Hospital, Paris-Seine-Saint-Denis University Hospital, APHP, Bobigny, France,[6]Hôpital Européen Georges Pompidou, AP-HP, Paris, France

Adeno associated viral (AAV) vectors represent the leading platform for gene therapy. The exponential growth of clinical trials using AAV reflects the enormous potential of this system in various therapeutic areas. One of the key advantages of AAV vectors is the high versatility due to the large number of wild-type and engineered capsid variants, each characterized by specific tissue tropism. Capsid engineering strategies mainly rely on the generation of library of millions of variants followed by selection steps allowing to retrieve the best candidates. One of the major issues related to this approach is the high frequency of non-viable capsids. The incomplete understanding of the consequence of amino acid variations in capsid stability still poses a major problem in capsid engineering. In this context, the study of wild-type capsids might help in the identification of the regions that mostly tolerate the mutations. In 2020, we screened a cohort of 1319 human liver tissues and isolated 59 new capsid variants equally distributed in two distinct subtypes: AAV2 and AAV2-13 hybrids (La Bella T et al. 2020). AAV vectors derived from these new capsids were characterized in terms of manufacturability and *in vitro* transduction efficiency. In total, 70% of the capsids were successfully produced and infectious in cells, whereas 17 variants were non-viable. AAV production was correlated to capsid mutations in order to identify common features in non-viable variants. We postulated the independency of the mutations and developed a prediction method based on publicly available data. In 2019, Ogden and colleagues characterized the complete AAV2 capsid fitness landscape of all single-codon substitutions, insertions and deletions across the VP (Ogden PJ et al. 2019). The fitness score of the corresponding single amino acid variations was associated to each mutation present in our variants. Mutations were categorized in common and unique based on their frequency in our series. No differences in fitness score of common mutations was found in viable and non-viable capsids, whereas unique mutations had a significantly decreased score in non-viable capsids. Unique mutations displayed a bi-modal distribution which allowed the definition of a threshold for deleterious mutations. Deleterious mutations identified in our series and in Ogden library shared common features related to their localization in the 3D structure of the capsid, they inversely correlated with accessibility and localization in hyper variable regions. Moreover, deleterious mutations occurring in buried residues were enriched in hydrophobic-to-hydrophilic variations. Non-viable capsids were characterized by the presence of one or multiple unique deleterious mutations. We experimentally validated the effect of the predicted deleterious mutations by assessing capsid production of reverse mutants which resulted viable. In addition, this approach was validated on other collections of mutated AAV from public data.

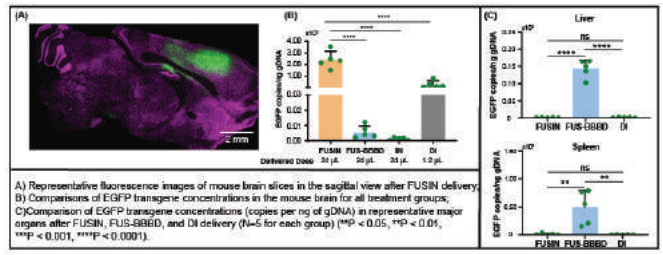
Our model was able to infer the fitness of variants with multiple amino acid variations by assuming the independence of the single mutations with a 94% of accuracy. This novel approach might be useful to guide the design of engineered capsids and might be adapted to other AAV serotypes relevant in gene therapy field.

875 Focused Ultrasound-Mediated Intranasal Delivery of AAV to Targeted Brain Regions with Minimal Systemic Exposure

Dezhuang Ye, Jinyun Yuan, Yaoheng Yang, Yimei Yue, Zhongtao Hu, Siaka Fadera, Hong Chen

Biomedical Engineering, Washington University in Saint Louis, Saint Louis, MO

Background, Motivation and Objective Gene therapy is a promising approach for treating various brain diseases, and adeno-associated virus vectors (AAVs) have been extensively used as gene transfer vehicles to the central nervous system (CNS). Efficient and safe delivery of AAVs to the brain is the major challenge to the clinical translation of AAV-based gene therapy to treat brain diseases. Intravenous injection (IV) of AAV requires a unique BBB-permeable capsid design and suffers from the risks of severe systemic toxicity. Direct intracerebral injection (DI) of AAV is invasive, and the expression is limited to the injection region. This study aims to demonstrate that focused ultrasound-mediated intranasal delivery (FUSIN) can achieve safe and efficient delivery of AAV to spatially targeted brain locations with minimal systemic exposure in mice. **Statement of Contribution/Methods** AAV5 encoding enhanced green fluorescence protein (EGFP) fused to the Synapsin promoter (AAV5-hSyn-EGFP) was administered through the nasal route to the mouse brain, followed by focused ultrasound (FUS) sonication targeting the cortex in the presence of systemically injected microbubbles. Mice delivered with AAV5-hSyn-EGFP by DI, FUS-mediated blood-brain barrier disruption (FUS-BBBD), and intranasal delivery (IN) were used for comparison (n=5 per group). Four weeks following AAV delivery, mice were sacrificed and transcardially perfused. The mouse brains and other major organs were harvested for analysis, including histological staining of brain slices, and PCR quantification of EGFP transgene of mouse brains and major organs. **Results/Discussion** EGFP fluorescence signals were observed in the targeted cortical brain area, indicating that AAV5-hSyn-EGFP was successfully delivered by FUSIN and carried EGFP transgene was subsequently expressed (Figure A). The PCR quantification found that FUSIN achieved 414.9-fold higher EGFP transgene expression than FUS-BBBD ($p < 0.0001$), 2073.7-fold higher than IN ($p < 0.0001$), and 8.7-fold higher than DI ($p < 0.0001$), as shown in Figure B. Limited by the injection volume, the AAV dose for DI was 20.0-fold lower than that of FUSIN. FUSIN delivery resulted in minimal systemic accumulation in major organs, including the spleen, liver, kidney, and heart, when compared with FUS-BBBD and DI (Figure C). **Conclusion** The lack of noninvasive methods for efficient delivery of AAVs to the brain with minimal systemic toxicity limits the development of gene therapy for treating brain diseases. This study demonstrated that FUSIN achieved efficient AAV delivery and gene transduction at the targeted brain region with minimal systemic exposure of the AAVs to other major organs. Findings from this study suggest that FUSIN is a promising technology for AAV delivery to the brain with the potential to be translated to the clinic for the treatment of CNS diseases.



876 High Resolution Biodistribution Analysis Following Suprachoroidal Administration of a Pool of AAV3B, AAV8, and AAV9 Vectors to Non-Human Primates Reveals Spatial and Cell-Based Tropism Differences

April R. Giles, Brendan M. Lilley, Sigmund K. Tejada, Trang Nguyen, Christieann Aprea, Sungyeon Cho, Ryan N. Clarke, Samitha Venu, Jason Yang, Elad Firnberg, Samantha A. Yost, Ye Liu, Olivier F. Danos, Andrew C. Mercer

REGENXBIO Inc., Rockville, MD

Delivery of adeno-associated viral (AAV) vectors to the eye has the potential to address unmet needs associated with many ocular disorders. While subretinal (SR) delivery of AAV can be an effective therapy due to significant transduction of the retina and retinal pigment epithelium (RPE), it is a specialized procedure requiring surgery in an operating room. Intravitreal (IVT) delivery, while less invasive, has been associated with significant ocular inflammation. Targeted delivery to the suprachoroidal space (SCS) using transscleral microneedles can be performed in-office and may cause less inflammation than IVT delivery. AAV transduction following SCS delivery is not well-characterized compared to SR and IVT. In this study, we assessed biodistribution and transduction efficiency of a small pool of AAVs following SCS delivery in cynomolgus macaques. Based on the results of a pilot study in which we delivered a 118-member AAV library to the SCS in three NHPs, we selected AAV3B, AAV8, and AAV9 for further evaluation. AAVs were each produced twice, once packaging a primate protein-coding sequence with a unique barcode and once packaging a fluorescent reporter (GFP, tdTomato, or iRFP670). The six resulting preps were then formulated into a six-member pool, with fluorescent reporter preps comprising 85% of the vector pool and native transgene preps comprising 15%. This formulation method allowed us to obtain comparable biodistribution and expression data from each capsid by PCR and next-generation sequencing (NGS) using the vector genomes and mRNA transcripts from the primate protein-coding gene constructs as well as to visualize protein expression of each fluorescent reporter by histology. Following suprachoroidal delivery of the resulting pool to both eyes of three NHPs, right eyes were fixed whole for histology and left eye tissues were harvested for PCR/NGS three weeks later. Posterior tissue was dissected into quadrants, and 6mm punches from central and peripheral regions of the retina, RPE/choroid, and sclera from each quadrant were collected. Irrespective of location, retina, RPE/choroid, and sclera contained 0.5, 3.8, and 95 GC/cell on average resulting in 0.12, 3.3, and 44 transgene RNA copies/TBP mRNA copy, respectively. These data suggest that retinal and RPE/

choroid transduction by AAV is less efficient overall than scleral. After spatially disaggregating the data, peripheral regions were more highly transduced than central regions in all tissues: 2.7 to 14-fold by DNA and 5 to 40-fold by RNA. By NGS analysis, AAV3B produced 1.7-fold more RNA in retina than AAV8 with equivalent DNA abundance. AAV8 produced 1.5-fold more RNA in RPE/choroid than AAV3B; however, after normalization by DNA abundance, AAV8 produced 10-fold less RNA per vector genome than AAV3B. Immunofluorescence revealed that both AAV3B (expressing tdTomato) and AAV8 (expressing GFP) preferentially transduced the RPE over the choroid, transducing 5-30% of cells in regions analyzed. NGS analysis of the sclera revealed that AAV3B transduced sclera 10-fold less efficiently than AAV8. Scleral expression of tdTomato was detected in less than 5% of the area of scleral regions of interest (ROIs), compared to up to 17% of the same scleral ROIs being GFP+. By NGS, AAV9 transduced RPE similarly to AAV3B, retina similarly to AAV8, with a modest 2-fold decrease in scleral transduction compared to AAV8; histological analysis is ongoing. Taken together, these data suggest that AAV3B and AAV8 have discrete tropisms following delivery to the SCS in NHP and their use may have unique advantages in an ocular gene therapy setting.

877 High-Throughput Method to Analyze the Cytotoxicity of CAR T Cells in a 3D Tumor Spheroid Model Using Image Cytometry

David Zurowski[1], Samir Patel[2], Daniel Hui[1], Mignane Ka[1], Charles Hernandez[2], Andrea Love[2], Bo Lin[2], Andrea Moore[1], Leo Li-Ying Chan[2]

[1]Resilience, East Norriton, PA,[2]Nexcelom From PerkinElmer, Lawrence, MA

Chimeric antigen receptor (CAR)-T cell therapy is an antigen-dependent cellular therapy that has gained considerable traction in the field of cancer immunotherapy. CAR-T cell therapy involves specifically engineering T cells to attack tumor cells by binding a tumor antigen and inducing T cell activation resulting in intracellular signaling and cytokine release. Currently, there are six FDA-approved CAR-T cell therapies, which all target the CD19 or BCMA antigens for hematologic B cell malignancies. In recent years, a strong focus has been placed on CAR T cell therapy discovery for solid tumors, which may better recapitulate physiological conditions, thereby potentially improving the selection of CAR construct candidates. Immune cell trafficking and immunosuppressive factors increase the relative difficulty in developing a robust CAR-T cell therapy against solid tumors. Therefore, it may be critical to develop novel methodologies for high-throughput phenotypic and functional assays using 3D tumor spheroid models to better assess CAR-T cell therapies against solid tumors. Recently, plate-based image cytometry has emerged as a method to investigate and characterize CAR T cell functions in a high-throughput manner. Image cytometry has demonstrated capabilities in analyzing transduction efficiency, cell proliferation, and cytotoxicity for CAR T cell therapy. With the development of 3D spheroid models, image cytometry may provide the necessary tools and applications for CAR T cell therapy discovery geared towards solid tumors. In this work, we discuss the use of CAR-T cells targeted towards PSMA, an antigen that is found on prostate cancer tumor cells, the second most common cause of cancer deaths among men worldwide. Herein, we demonstrate the use of high-throughput plate-based image cytometry to characterize PSMA CAR-T cell-mediated cytotoxic potency against 3D prostate tumor spheroids and simultaneously monitor location of the T cells *in vitro*. We were able to kinetically evaluate the efficacy and therapeutic value of PSMA CAR-T cells by analyzing the cytotoxicity against prostate tumor spheroids. Furthermore, the T cells are fluorescently labeled with a tracer dye to visually locate the cells on the tumor spheroids. The proposed image cytometry method can potentially overcome limitations placed on traditional methodologies to effectively assess cell-mediated 3D tumor spheroid cytotoxicity and efficiently generate time- and dose-dependent results.

878 ATHENA I System: A High-Throughput AAV Variant Comparison and Selection Platform

Cheng Xu, Zhen Shi, Yu Liu, Rongze Yang, Cuiping Chen, Daozhan Yu, Qizhao Wang

AAVnerGene Inc, Rockville, MD

AAV vectors are powerful tools for gene delivery and therapy, however, currently used AAVs are of low efficiency, which leads to high doses, high side effects, high costs and also manufacturing problems. Hundreds of identified natural AAV serotypes and an increasing number of engineered variants allow us to find highly efficient AAVs for each cell type and tissue, although it is difficult to identify the best AAV for each target quickly. To solve this problem, we have developed a novel platform, ATHENA I, for rational capsid comparison and selection. In this platform, each capsid variant packages an identical reporter gene with three unique DNA barcodes. Hundreds of AAV vectors can be generated at once, pooled and tested together in vivo or in vitro. DNA and transcribed RNA barcodes are then quantified by NGS to evaluate putative capsids for each target. Efficacy of each AAV candidate is obtained by directly comparing the abundance of the barcodes in NGS data before and after infection rather than comparing with other AAV variants. In this way, it reduces most of the variables and the results are more accurate and reliable. We harnessed the ATHENA I platform to evaluate 88 different AAV variants in two different mouse models after systemic injection: wt 129/SV and liver-humanized C57BL/6. At RNA level, AAV8-Y447F-Y733F, AAV-DJ, Anc80L65, AAV8, AAV10.1, AAV-DJ8, AAV-Rh.74, AAV10, AAV-SCH9 and AAV7 were the top 10 AAV variants in wt 129/SV liver. At DNA level, AAV-DJ, AAV2-Y444F-Y500F, AAV-Rh.74, AAVrh10, AAV10.1, AAV7, AAV8, AAV-DJ8, AAV7-Y446F-Y732F and AAV-SCH9 were the top 10 AAV variants. The performance of each AAV variant was different in liver-humanized C57BL/6. The top 10 AAV variants at RNA level were AAV9-PHP.S-Y354H, AAV9-PHP.S, AAV9-F, AAV9-Y446F-Y731F, AAV6.2FF, AAV-DJ, AAV8-Y447F-Y733F, Anc80L65, AAV-SHH10 and AAV9-PHP.B and the top 10 at DNA level were AAV2-retro, AAV9-Y446F-Y731F, AAV9, AAV3B-Y445F-Y731F, Anc80L65, AAV2, AAV9-PHP.S, AAV9-PHP.S-Y354H, AAV-DJ8 and AAV3B. These results confirmed that AAV8 and its Y/F mutants are better candidates for mouse liver, while in the liver-humanized C57BL/6, AAV9 and its variants outperform both at RNA and DNA levels. With ATHENA I, we also confirmed AAV9-PHP.eB and AAV9-PHP.B had the best performance to cross blood-brain barrier (BBB) in both RNA and DNA levels in the brain of liver-humanized C57BL/6, but they didn't work very well in wt 129/SV mouse brain. In contrast, AAV-F had the highest RNA and DNA in 129/SV mouse brain. AAV6.2FF, AAV10, AAV6.2, AAV5 and AAV-Rh.74 showed similar or higher crossing BBB activity compared with AAV9

in wt 129/SV mouse as measured by RNA expression. At DNA level, AAVrh10, AAV-Rh.74, AAV9-Y446F-Y731F, AAV7, AAV-DJ, AAV7-Y446F-Y732F, AAV-DJ8, AAV2, and AAV2-Y444F-Y500F were better than AAV9. In the liver-humanized C57BL/6 moue brain, AAV6.2FF, AAV10.1, AAV1, AAV4-Y729F, AAV1-Y445F-Y731F, and AAV10 had better performance at RNA level, while AAV1-Y445F-Y731F, AAV-Rh.74, AAV1, AAVrh10, AAV-DJ8, AAV7, AAV10.1, AAV9-Y446F-Y731F, AAV8, and AAV7-Y446F-Y732F had better performance at DNA level compared with AAV9. These results showed that rather than AAV9, other AAV serotypes could be used as template for AAV capsid library construction to select the AAV variants which are able to cross BBB. These results showed AAV variants in a different models, different detection level(DNA and RNA) will have different outcomes. A cross-species evaluation may help select potent AAV variants for human gene therapies. With ATHENA I, we can effectively compare efficiency of hundreds of AAVs in a fast and high-throughput way in different animal models in both DNA and RNA levels, select the best AAV for a specific disease therapy, and design even better AAVs. We now have more than 1000 AAV variants and similar works have been executed in NHPs. The results will be reported soon. Multiple tissue-specific ATHENA I kits are also available for collaboration.

879 Enrichment of Genetically Modified Hematopoietic Stem Cells through Multiplex Base Editing

Panagiotis Antoniou[1,2], Giulia Hardouin[1], Steicy Sobrino[1], Annarita Miccio[1]

[1]IMAGINE Institute, Paris, France,[2]Genome Engineering, Discovery Sciences, BioPharmaceuticals R&D Unit, AstraZeneca, Gothenburg, Sweden

β-hemoglobinopathies are caused by mutations affecting the adult hemoglobin (Hb) production. Transplantation of autologous, genetically modified hematopoietic stem/progenitor cells (HSPCs) is an attractive therapeutic option. The clinical severity of β-hemoglobinopathies is alleviated by the co-inheritance of mutations causing hereditary persistence of fetal Hb (HbF) (HPFH) mapping to the fetal γ-globin (*HBG*) gene promoters. Base editing (BE) allows the introduction of HPFH point mutations (C>T by cytidine base editors, CBEs; A>G by adenine base editors or ABEs) without generating double-strand breaks (DSBs).We previously reported that introduction of HPFH mutations in the *HBG* promoters using CBE or ABE leads to therapeutically relevant HbF levels in red cells differentiated from patient's HSPCs. Xenotransplantation experiments showed BE in long-term HSCs; however, the efficiency was reduced compared to input HSPCs. BEs might have induced some toxicity in *bona fide* HSCs or might be less efficient in this cell population compared to progenitors. *Ex vivo* or *in vivo* enrichment of edited HSCs could be exploited to maximize the engraftment of genetically modified cells. This could also allow the reduction of the conditioning regimen and its side effects. Such an approach could increase the success of therapeutic strategies for diseases with no or little selective advantage of corrected cells such as β-hemoglobinopathies.Here, we developed a strategy enriching for base-edited HSPCs to achieve high BE efficiencies *in vivo*, and eliminate unedited HSCs that might have a survival advantage and better stemness compared to edited cells. We used BEs (that allow multiplex editing without generating genomic rearrangements) to simultaneously target the *HBG* promoters and insert HPFH mutations, and the *CD33* gene to downregulate CD33, a receptor expressed by HSCs with a high regenerative potential, but dispensable for hematopoietic cell activity. Selection of *CD33* knock-out (KO) HSPCs will also enrich for cells edited at the *HBG* promoters.We designed sgRNAs that target *CD33* and, when coupled with CBEs or ABEs, disrupt *CD33* start codon, or splice donor/acceptor sites. We screened sgRNAs in an erythroid cell line (K562) and identified efficient sgRNAs downregulating *CD33*, achieving BE efficiencies of up to 80%, and a concomitant 5-fold CD33 downregulation. We then performed multiplex base editing by simultaneously targeting *HBG* and *CD33* in K562 cells. We observed no statistically significant difference in BE efficiency between single and dual editing conditions. Upon FACS-sorting based on CD33 expression, we observed higher BE efficiencies at *HBG* in $CD33^-$ vs $CD33^+$ populations, thus indicating elimination of poorly edited cells in the $CD33^-$ compartment.We applied the dual editing strategy in patient HSPCs selected based on the expression of CD34 (a typical marker of HSPCs). Two days post-transfection, control and edited cells expressed similar CD34 levels, while only edited cells showed a strong decrease in CD33 expression. $CD33^-$ and $CD33^+$ populations were FACS-sorted. Importantly, we detected higher BE efficiencies in $CD33^-$ *vs* $CD33^+$ populations at *HBG* promoters. A colony-forming cell assay revealed no difference in the progenitors' number, differentiation and viability between control and $CD33^-$ sorted populations.In conclusion, we showed that multiplex editing of *HBG* promoters and *CD33*, in conjunction with $CD33^-$ selection leads to high BE efficiencies and eliminates poorly edited cells. Importantly, this strategy can be used to enrich for edited cells and develop effective therapeutic for many hematopoietic and non-hematopoietic diseases amenable to HSC-based gene therapy treatment.

880 Development of Oral Cancer Vaccine by Using Recombinant Saccharomyces Cerevisiae Displaying Wilms' Tumor 1 Protein

Koichi Kitagawa[1], Ruhan A[1], Kentaro Inokuma[1], Yuka Yoshigoe[1], Tomohisa Hasunuma[1], Toshiro Shirakawa[2]

[1]Kobe University Graduate School of Science, Technology and Innovation, Kobe, Japan,[2]Kobe University, Kobe, Japan

In recent years, cancer immunotherapy using immune checkpoint inhibitors has been used with great success in treatment of various types of cancer such as bladder cancer. However, monotherapy of immune checkpoint inhibitor by using anti-programmed death-1 (PD-1) showed the objective response rate of approximately 21% in advanced bladder cancer. Therefore, combination of immunotherapy will be a promising modality to improve the response in bladder cancer patients. Previously, we had constructed a recombinant *Bifidobacterium longum* displaying Wilms' tumor 1 (WT1) protein, and had shown the significant anti-tumor effect in mice. In this study, we newly constructed recombinant *Saccharomyces cerevisiae* displaying WT1 protein (BY-WT1) to achieve more efficient expression of the WT1 protein, higher productivity and higher efficiency in anti-cancer effect than predecessor. To construct the BY-WT1, parental *S. cerevisiae* strain was transformed by plasmid vector and the protein expression was determined by real-time RT-PCR and western blotting. To investigate the anti-tumor effect of BY-WT1, 3.6 mg per dose of BY-WT1 was orally administered 5 times a week into C3H/He mice bearing syngeneic MBT-2, a murine bladder cell line. Intraperitoneal

injection of 10 μg of anti-PD-1 antibody was performed with oral administration. Spleen cells were isolated to determine WT1-specific T cell immune responses and cytotoxicity against MBT-2 *in vitro*. As the results, recombinant *S. cerevisiae* successfully expressed WT1 protein on the yeast cell wall. Oral administrations of BY-WT1 remarkably inhibited the tumor growth as well as anti-PD-1 therapy in mice bearing MBT-2. In addition, combination therapy of BY-WT1 and anti-PD-1 significantly decreased the tumor growth compared with PBS control at days 29 after tumor inoculation ($p<0.05$). Oral administrations of BY-WT1 significantly increased the population of CD4T and CD8T cells that were secreting WT1-epitope-specific cytokines such as IL-2, and TNF-α in mice ($p<0.05$, respectively). Furthermore, oral administration of BY-WT1 induced remarkably higher cell cytotoxic activity in splenocytes against MBT-2 *in vitro*. In conclusion, we showed that the combination of oral administration of recombinant *S. cerevisiae* displaying WT1 and intraperitoneal injection of immune checkpoint inhibitor induced WT1-specific T cell responses and resulting anti-tumor effect in syngeneic mice model. Our findings suggested that the cell surface engineering technology for *S. cerevisiae* could be a possible approach for intestinal immune system and BY-WT1 may be a new therapeutic candidate for advanced bladder cancer.

881 An Adeno-Associated Virus-Based Gene Replacement Therapy for Type II Gaucher Disease

Yezheng Tao, Jing Ma, Pengjuan Ma, Liang Lu, Xi Zhu, Xiaoping Zhao, Shin-Shay Tian

Vitalgen BioPharma Co, Shanghai, China

Gaucher disease (GD) is a rare genetic lysosomal storage disorder caused by mutations in the glucosylceramidase beta 1 (GBA1) gene which encodes lysosomal enzyme acid GCase. Inadequate activity of GCase causes the progressive accumulation of the sphingo-lipid glucosylceramide in lysosomes of macrophages (referred to as Gaucher cells), mainly in the liver, spleen, bone, and bone marrow, which eventually leads to the dysfunction of multiple organs. There are three types of GD, Types 1, 2, and 3). GD2 and GD3 are less common than GD1 and are mainly dominated by neurologic pathologies in terms of clinical presentation, especially GD2. The ERT of GCase protein has been developed for treating GD1 to ameliorate most of the symptoms and improve patient's quality of life. For GD2 patients, there is no effective treatment since the recombinant enzyme drug cannot pass through the blood-brain barrier and has limited effects on reducing neurological symptoms. In GD3, the progression of brain damage is not as rapid as GD2, so ERT can relieve most of the systemic manifestations and extend patients' life-span significantly, though a retarded mental development (encephalopathy) is often observed. So, new treatment is urgently needed to restore the GCase activity in the central nervous system (CNS), to help patients that are diagnosed with GD2 and GD3. We have developed an investigational gene therapy, VGN-R08b, which utilized non-replicating virus (a recombinant AAV9) as a vector to deliver genetically modified functional human GBA1 gene into human cells. By intra-cerebroventricular administration of VGN-R08b, we aim to restore the GCase activity in the brain of GD2 and GD3 patients, thus relieving the neuropathic symptoms caused by the accumulations of sphingo-lipid glucosylceramide in the CNS with a one-time treatment. Our results showed that in a GCase loss-of-function cellular model, VGN-R08b effectively restored the GCase activity. In a conduritol B epoxide (CBE) induced mouse model of GD2, VGN-R08b significantly improved the viability, locomotor activity, and motor coordination of the GD-induced mice. Preliminary mouse safety studies demonstrated that VGN-R08b is well tolerated. An investigator-initiated-trial of VGN-R08b is ongoing in China.

882 Human RHO Editing for Treatment of Autosomal Dominant Retinitis Pigmentosa

Arjun Padmanabhan[1,2], Federica Esposito[1], Mariangela Lupo[1], Elena Marrocco[1], Manel Llado Santeularia[1], Ivana Trapani[1,3], Alberto Auricchio[1,2,3]

[1]Molecular Therapy Program, Telethon Institute of Genetics and Medicine (TIGEM), Naples, Italy,[2]Genomic and Expeirmental Medicine Program(GEM), Scuola Superiore Meridionale(SSM), Universita degli studi di Napoli Federico II, Naples, Italy,[3]Medical Genetics, Department of Advanced Biomedical Sciences, Universita degli studi di Napoli Federico II, Naples, Italy

Retinitis Pigmentosa (RP) affects 1/3.000 patients worldwide, with 30-40% of cases having an autosomal dominant (AD) inheritance. The rhodopsin gene (RHO) is the most commonly mutated in AD RP patients (RP4), with the P23H gain-of-function mutation being the most common in US. Canonical gene therapy approaches that add a correct copy of the gene, are not beneficial and removing the mutant RHO allele is necessary to avoid its toxic effect. The CRISPR-Cas9 based allele-specific editing has emerged as a therapeutic option for dominant RP by blocking the production of the toxic protein without affecting the correct copy of the gene. However, this approach limits its applicability to all RP4 patients, as design of a gRNA specific for each mutation would be required. We have recently described Homology-Independent Targeted Integration (HITI) which uses adeno-associated viral (AAV) vectors to deliver both CRISPR-Cas9 and a donor template to be integrated at the mouse RHO locus. This blocks the expression of the endogenous RHO and replaces it with its wild type copy. Here we have designed AAV-HITI that targets the human RHO locus, and tested it in a recently described P23H knock-in mouse model of RP4 .We performed subretinal injections into hRHO-P23H-tagRFP mice, with two AAV8 vectors, encoding the Cas9 and the donor DNA (carrying both RHO and GFP to label photoreceptors where integration occurred) respectively. The contralateral eye served as control. HITI efficiency was calculated by microscopy analysis on retinal sections by counting the GFP fluorescence in the outer nuclear layer (ONL).One month after injection, retinal electrical activity was measured by electroretinogram (ERG) in homozygous mice.At 30 days post-injection, we have observed HITI efficiency up to 12±8% in the transduced area (n=4) and an improved retinal electrical function (B-wave) as measured by ERG (p=0,005; n=10). Prospectively, we plan to evaluate the improvement in the retinal phenotype at advanced timepoints and potential off-targets editing events. Our preliminary results provide the first proof-of-concept of the efficacy of HITI as a therapeutic strategy for AD RP due to RHO mutations in a humanised mouse model and therefore, it could be readily translated to a human setting.

883 Human Beta2-Microglobulin (B2M) Knockdown as an *In Vitro* Model to Evaluate CRISPR Delivery

Molly E. Cassidy[1], Karthikeya S. V. Gottimukkala[1,2], Daniel Douglas Lane[1], Youngseo Jwa[1], Jennifer E. Adair[1,2]

[1]Fred Hutchinson Cancer Center, Seattle, WA,[2]Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA

Previously, our lab reported gold nanoparticles carrying CRISPR components (CRISPR-AuNP) for gene editing primary human hematopoietic stem and progenitor (HSPCs) ex vivo. Optimization of CRISPR-AuNP include changes to the target locus for editing, homology directed repair templates, addition of other moieties for altered function and specificity, and changes to steps in formulation. With each alteration, testing efficiency of gene editing and toxicity in vitro can help determine potential translation to animal models. However, DNA sequencing alone takes time and resources, and isn't always relatable to functional changes in cellular biology at the protein level. We sought to establish a high-throughput, reliable in vitro model for evaluating multiple delivery strategies across human cell and tissue types. The human β-2-microglobulin (B2M) gene is a small, highly conserved sequence whose protein product is a component of major histocompatibility complex (MHC) class I, expressed ubiquitously on the surface of most cell types. Other groups have documented the utility of CRISPR-based editing of B2M for therapeutic purposes in immunology, with indels resulting in loss of B2M surface protein expression measured by flow cytometry. Here we tested B2M as a single-gene target model for CRISPR delivery in vitro. Readouts included loss of cell surface B2M protein expression, MiSeq™ next generation DNA sequencing, and T7 endonuclease I (T7EI) assay. We tested Jurkat and K562 cells by electroporating Cas9 or Cas12a ribonucleoprotein (RNP) complexes targeting B2M but observed low protein knockdown with the published Cas12a guide RNA sequences (gRNA) (64.4%±2.3% for Cas9 and 2.9%±1.1% for Cas12a). We identified five additional Cas9 gRNA binding sites and five Cas12a gRNA binding sites to test. Electroporation studies in HSPC (n = 3 unique donors) and primary human T cells (n = 1 unique donor) identified one gRNA for each nuclease type which resulted in superior gene editing by flow cytometry, MiSeq™ and T7E1 (Fig. 1a and 1b, respectively). We tested this approach in other cell lines by electroporating RNP with or without interferon gamma (IFN-γ) to increase B2M expression and compared to mock-treated samples as a negative control. Cells were analyzed 48-hours post electroporation. All seven cell lines tested showed > 5% reduction in B2M surface protein expression compared to control with either a Cas9 or Cas12a gRNA (Fig. 1c, range: 5%-58%), which is currently being validated by MiSeq™ and T7EI assay. Finally, we tested CRISPR-AuNP delivery, originally validated at a different, non-B2M genetic loci, with an updated particle design (See abstract [2023-A-1421_ASGCT]) in HSPCs (n=1 unique donor), which resulted in 16.5%±4.6% B2M protein knockdown by flow cytometry, 8.3%±3.7% editing by MiSeq™, and 2.6%±1.8% editing by T7E1 (Fig. 1d). This suggests that CRISPR-AuNP delivery is associated with increased gene editing readout by flow cytometry compared to DNA sequence analyses. We later determined this to be a function of increased false positive signal from cationic polymer components (See abstract [2023-A-1795_ASGCT]). Altogether this study suggests B2M is a useful model for comparing gene editing efficiencies in vitro as a function of method of delivery.

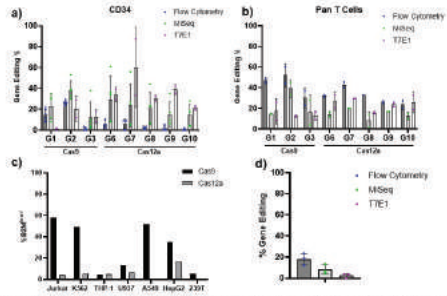


Figure 1. Evaluation of CRISPR gRNAs targeting B2M in a) G-CSF mobilized CD34+ cells (n=3 unique donors) b) Pan T cells (n=1 unique donor) c) immortalized cell lines (n=1) as follows: Jurkat (T cells); K562 (Bone; Marrow); THP-1 (Monocytes); U937 (Macrophages); A549 (Lung); HEPG2 (Liver); 293T (Kidney). d) CRISPR/Cas9-AuNP administered to HSPCs (n=1 unique donor).

884 Cardiomyocyte Death after AAV Gene Transfer Can Be Related to Proteotoxicity or to Transgene Abnormal Function or Localization

Biquand Ariane, Evelyne Gicquel, Poupiot Jérôme, Anthony Brureau, Isabelle Richard

GENETHON, Evry, France

Gene delivery technologies based on adeno-associated virus vectors (AAV) have yielded promising results for the treatment of monogenic diseases, leading in recent cases to marketing authorization in Europe and US. However, preclinical studies and clinical trials have highlighted that infusing high vector doses can trigger immune responses or induce cytotoxicity in a number of organs, leading in a few cases to the death of the patient. In the wake of signs of cardiac suffering in humans after gene transfer in SMA, DMD and MTM1, we investigated the consequences on the heart of administration of high doses of AAV vectors expressing 3 different transgenes corresponding to muscular dystrophies: a form of microdystrophin for Duchenne Muscular Dystrophy, the human full-length SGCG cDNA for γ-sarcoglycanopathies and the human full-length FKRP cDNA for FKRP deficiencies. We observed in all these cases the possibility of cardiotoxicity with high doses injection. Preventing transgene expression in heart through the use of a cardiac specific microRNA, miR208a, was shown to prevent the appearance of such cardiotoxicity, indicating that the cardiotoxicity was related to transgene expression in this organ. Dissection of the mechanisms at stake revealed activation of different cascades leading all to cardiomyocyte death. Overall, our data highlighted a specific sensitivity of the heart to transgene expression, in particular compared to skeletal muscle, suggesting the importance to regulate finely the expression of transgene in this organ in any gene therapy approach. The manuscript presenting this work is ready for submission.

885 Using TcBuster™ (TcB-M™) Transposase for Highly Efficient and Robust Delivery of Multicistronic Therapeutic Cargo in Immune Cells for Both RUO and Clinical Applications

Kirsti Walker[1], Kalyani Kota[1], Dalton Smedley[2], David Hermanson[2], Bryan Jones[3], Neil Otto[3], Xiaobai Patrinostro[1]

[1]New Product Development, Bio-Techne, Minneapolis, MN,[2]Applications, Bio-Techne, Minneapolis, MN,[3]R&D, Bio-Techne, Minneapolis, MN

Rapid development of genome engineering tools has driven several immune- and stem cell therapies in clinical trials with the goal of generating autologous and allogeneic therapeutics. Many of these therapies use viral vectors for the delivery of therapeutic cargo. However, viral mediated therapies carry the risk of immunogenicity, cargo size limitations, integration site risk, manufacturing delays, and is highly cost prohibitive. While there are a couple of known non-viral transposase-based systems, such as, PiggyBac and Sleeping Beauty, both are exclusively licensed and not available for commercial use. TcBuster-M™ (TcB-M™) is a commercially available non-viral transposase-based editing platform that overcomes current viral limitations. TcBuster is found in the red flour beetle and is a member of the hAT family of transposases. Using direct evolution, we engineered a hyperactive mutant (TcB-M) that has improved transposition rates using less mRNA transposase and plasmid DNA transposon. Divergent from the engineering efforts used to build hyperactive enzymes of PiggyBac and Sleeping Beauty, we used a novel high-throughput screening platform in mammalian cells. This allowed us to screen a mutant library of > 3 million variants, which is much larger than those used to build PiggyBac or Sleeping Beauty. This led to the construction of the most efficient transposase system for engineering primary immune cells. TcB-M allows for rapid cell manufacturing with limited cell manufacturing cost. Current TcB-M timeline from vector map to GMP transposon is ~6-8 months. Since TcB-M is less constrained by cargo size, we can design large multicistronic transposons for robust delivery of multiple proteins in various cell types, including primary T- and NK- cells, mesenchymal stem cells, and induced pluripotent stem cells (iPSCs). Additionally, TcB-M can be easily combined with endonucleases, such as CRISPR reagents, to generate combinatorial knock-out/overexpression edited cell products. The improved TcB-M has resulted in cargo integration rates of over 60% in primary T-cells and peripheral blood derived NK cells, without sacrificing cell growth or clonal dominance concerns. Finally, we have conducted direct comparisons against lentiviral, PiggyBac, and Sleeping Beauty engineered CAR-Ts, demonstrating TcB-M engineered CAR-Ts has equal to higher integration percentage. TcB-M also has a safer integration profile as it is more randomly integrated into the genome without preference to active sites when compared to Lentivirus. Overall, TcB-M is a widely available proven non-viral gene editing technology to deliver large or difficult therapeutic cargos in a variety of cell types. TcB-M thus reduces many of the viral mediated editing hurdles, allowing faster generation of crucial therapeutics to market.

886 Development of an iPSC-Derived Cell Therapy for Limb-Girdle Muscular Dystrophy Type 2A/R1

Congshan Sun, Casey Barber, Andrew Coleman, Oscar Safairad, Sheela Jacob, Amir Saberi, Luke Ren, Amy Wesa, Capela Alexandra, Douglas Falk, Peter Andersen

Vita-therapeutics, Baltimore, MD

Limb-girdle muscular dystrophy type 2A/R1 (LGMD2A/R1) is a rare form of muscular dystrophy with around 4000 patients in the US and approximately 80-100 new patients identified every year. LGMD2A/R1 is caused by mutations in the CAPN3 gene, which leads to loss of functional calpain-3 protein, resulting in symmetrical muscle wasting of the proximal limb and girdle muscles. There is currently no approved treatment for LGMD2A/R1. Regenerative therapies derived from induced pluripotent stem cells (iPSCs) may provide a promising approach to regenerate muscle mass associated with muscle wasting. Here we describe the pre-clinical development of an iPSC-based autologous therapy for LGMD2A/R1. A CRISPR-based knock-in strategy was developed to replace the endogenous defective *CAPN3* gene with a functional version in LGMD2A/R1 patient-derived iPSCs. Using a chemically defined, step-wise myogenic lineage specification protocol, PAX7-expressing myogenic progenitor cells (MPCs) were then generated; upon myogenic fusion induction, these cells formed functional myotubes that produced *CAPN3* mRNA and protein. We then transplanted *CAPN3* edited LGMD2A/R1 iPSC derived MPCs into the injured TA muscles of NSG mice and demonstrated donor cell-derived muscle regeneration. Furthermore, a subpopulation of transplanted MPCs seeded in the local muscle stem cell niche area under the basal lamina in mice where they adopt a quiescent state and contribute to regeneration upon additional injury, thus providing evidence of a long-term maintenance and regenerative capability. To facilitate *in vivo* efficacy studies in an animal model of LGMD2A/R1, we generated an immunodeficient calpain-3 null mouse by back-crossing CAPN3KO mice (JAX: CC041-Capn3em10Lutzy/J) with NSG (JAX: NOD.Cg-Prkdcscid Il2rgtm1Wjl/SzJ) mice. Intramuscular transplantation of *CAPN3* edited MPCs into injured muscle of CAPN3KO-NSG mice leads to donor-derived muscle fiber regeneration, supporting the rationale for continued development. Manufacturing of LGMD2A/R1 iPSC-derived MPCs to support IND-studies and first-in-human trials is ongoing with the goal of IND-filing.

887 Automated Micro-TFF System Streamlines Purification and Operator Time in a Lean rAAV Manufacturing Operation

Shireen Abesteh, Ivona Filic, Brandon Lippert, Erik A. Lykken, Nishith Nagabhushana, Christopher P. Reardon, Abigail Rose Sheridan

Dyno Therapeutics, Watertown, MA

Recombinant Adeno-associated virus (rAAV) doses greater than or equal to 1E13 vg/kg are required for pre-clinical or clinical studies with increasing frequency. Producing the desired doses often requires concentrating rAAV drug substance from a starting volume of one hundred milliliters down to ≤ fifteen milliliters during final formulation. For these applications, Molecular Weight Cut Off (MWCO) centrifugal filtration devices (spin filters) are commonly

employed to concentrate and exchange buffers on the rAAV drug substance. MWCO spin filters can fulfill this function, but require long hands-on time for full buffer exchange or viscous starting products such as those containing iodixanol. Additionally, MWCO spin filters provide inconsistent process control due to dependencies on multiple variables (including volume, concentration, viscosity, and spin time) and lack in-spin progress monitoring. In a lean rAAV manufacturing operation, the operator hands-on time requirement represents a substantial production bottleneck. To relieve this bottleneck, we evaluated a commercially available small volume tangential flow filtration (TFF) device, which has walk-away automation and the ability to concentrate material from one hundred milliliters to one milliliter. In our evaluation, transitioning to an automated TFF system yielded advantages in operator hands-on time, step-yield, and process consistency. We additionally observed consistent performance across a variety of rAAV serotypes, thus demonstrating its value in a lean and serotype-varied rAAV manufacturing operation.

888 A Process Development Approach to a Platformable and Robust Scale Up for Enrichment of Full AAV Capsids Using Membrane Chromatography

Julio M. Huato, Mark Schofield, Aydin Kavara, Kurt Boenning, Isabella Depina

Pall Corporation, Westborough, MA

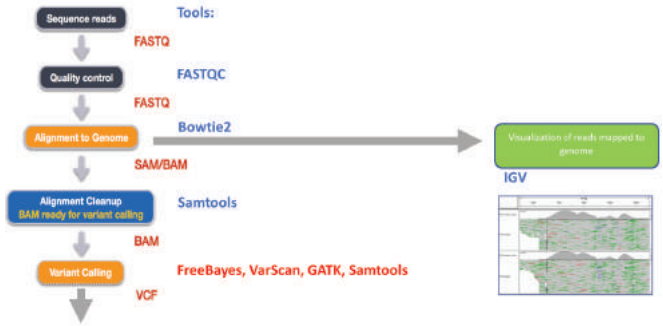
Adeno-Associated Virus (AAV) vectors are one of the current leading platform for gene delivery treatments. One of the most challenging aspects in manufacturing AAV is the removal of 'empty' capsids, which do not contain the gene of interest. Here we showcase a comprehensive approach for developing a robust scale-up process for the purification of full AAV capsids using Mustang® Q anion exchange membrane chromatography capsules. We have extended this approach to AAV serotypes 5, 8 and 9. Initial process development was performed using our novel 1 mS/cm conductivity step elution method. This multi-step elution strategy is a tool for screening for improved separation conditions and serves as a guide for conditions to facilitate elution of empty and full capsids with just two conductivity steps. We show a thorough two conductivity step, design space investigation, identifying operating conditions that achieve high purity and high yield. The selected operating space is then used to scale up this method into radial flow capsules such as the Mustang Q XT capsule 50 mL device. We present the results from our scale-up purification using Mustang Q XT capsules 50 mL and show purity and yield are comparable with the results obtained at the process development scale. Additionally, we show consistent performance across different Mustang Q capsules with several feedstreams from different industry relevant sources. Taken together, the data shows that Mustang Q capsules can be a robust and platformable process for the removal of empty AAV capsids.

889 A Computational Framework to Detect ITR Deletion for rAAV Vectors

Youngji Na, Eugenia Lyashenko, Sourav R. Choudhury

AAV Technologies Laboratory, Genomic Medicine Unit, Sanofi, Waltham, MA

Adeno-associated virus (AAV) is a promising vector for gene therapy. However, manufacturing recombinant AAV (rAAV) vectors can be challenging. The inverted terminal repeat (ITR) sequences that flank the gene of interest form highly stable T-shaped hairpins, which are critical for replication and encapsidation of viral DNA. The palindromic nature and high GC content make ITRs prone to truncations. In addition, mutations are challenging to detect with NGS-based methods. Deletions in the ITR region can lead to reduced efficiency in viral packaging and increased variability in downstream experiments. Since there is a lack of bioinformatics tools for ITR-specialized detection, we established a robust computational framework to assess ITR deletions for rAAV vectors using NGS data. We start by running FastQC for quality control of sequencing data. We validate the quality of sequencing data for downstream analysis based on the per base sequence quality and per sequence quality scores from FastQC. Then we align the NGS reads to rAAV vector genome using Bowtie2 and visualize sequence reads mapped to the genome using Integrative Genomics Viewer (IGV). From the IGV visualization, we were able to hone into locations which genome regions have deletions as well as distribution of depth of coverage of sequence reads. To get consistent quantitative detection of deletions, we applied 4 standard variant calling tools (FreeBayes, VarScan, GATK, Samtools) at customizing input QC parameters to assess presence and significance of any observed deletions and mutations.As proof-of-concept, we applied this computational framework to detect ITR deletions in a batch of 8 rAAV vectors encoding the same genome. One variant calling method (VarScan) identified statistically significant 44 nucleotide (nt) deletions in 3' ITR, promoter, and CDS at a low frequency (<5%) in a subset of these vectors. We also establish the need to triangulate analyses from multiple variant calling tools to conclusively confirm deletions in the ITR sequences. Identifying mutations in complex genomic regions can save substantial costs down the line and lead to more reproducible results in manufacturing AAV gene therapies.

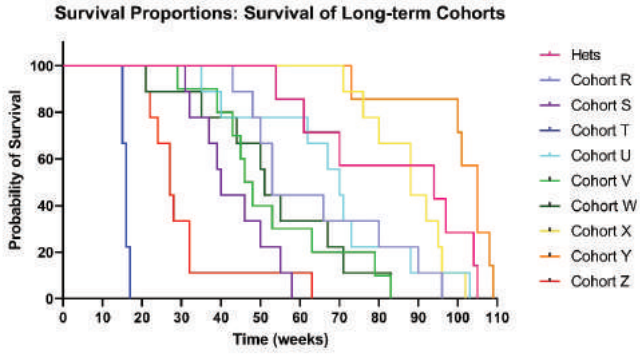


890 Dose Response of Dual Route *scAAV9-HEXM* Gene Transfer in a Mouse Model of Sandhoff Disease

Brianna M. Quinville[1], Alex E. Ryckman[1], Natalie M. Deschenes[1], Melissa Mitchell[1], Zhilin Chen[1], John G. Keimel[2], William F. Kaemmerer[2], Jagdeep S. Walia[1]

[1]Queen's University, Kingston, ON, Canada,[2]New Hope Research Foundation, North Oaks, MN

Sandhoff disease (SD) is caused by the excessive accumulation of GM2 gangliosides in the lysosomes of neuronal cells. Typically, these lipids are hydrolyzed by an enzyme, β-hexosaminidase A (Hex-A), a heterodimer comprised of an α- and a β-subunit. Mutations in the gene encoding either subunit can lead to improper functioning of the enzyme. SD is caused by a mutation in the *HEXB* gene resulting in a deficient or absent β-subunit and subsequent accumulation of GM2 gangliosides. This causes widespread cell death, and consequently progressive symptoms and rapid neurological decline culminating in death by age 4 in the most prevalent, infantile form of the disease. A homodimer formed by a novel hybrid μ-subunit called HexM, an isoenzyme of human Hex-A, has been recently developed and shown to hydrolyze GM2 gangliosides *in vivo*. Previous studies have determined the effectiveness of gene transfer with the gene, *HEXM,* packaged in a self-complementary adeno-associated viral vector, serotype 9 (scAAV9), through increased life span in a SD mouse model ($Hexb^{(-/-)}$). This study aims to determine the dose response of the *scAAV9-HEXM* treatment in the SD mouse model through dual delivery of treatment via intra-cisterna magna (ICM) and intravenous (IV) routes, along with the ancillary administration of immunosuppressant drugs. Treatment for 10 cohorts of 10 mice involved concurrent infusions through both ICM and IV routes. There were three possible infusates for the ICM route (vehicle, low or high vector dose) and six possible infusates (vehicle, 5 different vector doses) for the IV route. The study design allows an efficacy comparison of the total dose when administered either through one route of delivery or split between the two. The researcher who conducted the procedure and subsequent testing is blinded to which dosage each animal received. Bimonthly behavioural testing and blood collections at specific time points were done until mice reach their humane endpoint as determined by specific UACC criteria. At termination, blood, gross organs, brain, and spinal cord were collected for analysis of GM2 ganglioside accumulation, vector copy number, Hex enzyme activity, cellular and humoral immune response, and histology. To date the results from the long-term study show increased survival in all treatment groups compared to the vehicle-only control group ($p < 0.001$ in all cases). The treatment cohort with the longest survival showed a >6.5-fold increase in median survival compared to the control group. Additionally, some treated cohorts showed a >3-fold decrease in accumulated gangliosides compared to controls in the mid-section of the brain ($p < 0.01$). In sera collected at humane endpoints there was a >51-fold increase in Hex enzyme activity in the longest living treatment group compared to heterozygous controls ($p < 0.05$). Ganglioside accumulation in the cerebellum, Hex activity in the brain, vector biodistribution, and behavioural data will also be shown.



* Cohort T is the untreated (vehicle only) cohort, unblinded by virtue of their early death typical of SD mice.

891 Development of a Competitive Ligand-Binding Assay to Detect Neutralizing Antibodies Against Chimeric Antigen Receptor of Regulatory T Cells

Andres Gordillo Villegas, Montserrat Carrasco Triguero, Yanmei Lu, Yonghua Pan

Sangamo Therapeutics Inc, Brisbane, CA

Regulatory T cells (Tregs) have emerged as a potential treatment modality for various types of diseases. Tregs expressing chimeric antigen receptor (CAR) is being evaluated clinically for the treatment of human leukocyte antigen (HLA)- mismatched organ transplant rejection. Host immune response against the CAR protein represents a risk to clinical translation of CAR-T cell therapies due to its potential impact on safety and efficacy. The anti-CAR humoral immune response can generate antibodies that cause rapid clearance of CAR-T cells and may also neutralize CAR-Treg function. Therefore, development of appropriate assays to monitor and characterize anti-CAR antibodies is recommended by regulatory agencies and can ensure proper clinical development of the CAR-Treg cell products. Anti-CAR total antibodies (TAbs) have been detected using ligand-binding and cell-based assay formats. However, it is challenging to develop anti-CAR specific neutralizing antibody (NAb) assays, especially for the humanized CAR constructs due to the lack of commercially available assay reagents. This study will present the development of a competitive ligand-binding assay to detect NAbs against an engineered CAR, which is comprised of a humanized single-chain variable fragment (scFv). This scFv is designed to enable CAR Tregs to recognize and bind to the HLA-A2 antigen on donor kidney cells in HLA-A2 mismatched kidney transplantation patients. As a positive control, an antibody against the scFv was generated by rabbit single B-cell cloning technology and was able to specifically block the binding of the scFv to HLA-A2 *in vitro*. Using this anti-CAR NAb positive control, we evaluated both ELISA and MSD platforms and selected the MSD method based on better assay performance. The optimized MSD assay yielded a sensitivity of 141 ng/mL. Regarding drug tolerance, the assay detects 181 ng/mL of the positive control in the presence of 400 ng/mL of free scFv. In addition, we will discuss the challenges and strategies to implement cell-based anti-CAR NAb assays and improving NAb assay drug tolerance for tissue-targeting CAR-Treg cell therapy.

892 Engineering Non-Human Primate B Cells for Expression of Broadly-Neutralizing Anti-HIV/SIV Antibodies

Chan-Hua Chang, Geoffrey L. Rogers, Atishay Mathur, Xiaoli Huang, Paula M. Cannon

Molecular Microbiology and Immunology, University of Southern California, Los Angeles, CA

No vaccination strategy for HIV has been successful, in part because the antibodies that are induced are unable to neutralize the wide variety of circulating HIV subtypes, and resistance can easily be acquired by HIV mutation. In contrast, a small number of broadly-neutralizing antibodies (bnAbs) have been identified that provide good viral control, especially when used in combination. However, the use of recombinant bnAbs as an anti-HIV therapeutic would be costly and require life-long injections. As an alternative, we have previously described a genome editing approach at the IgG1 locus that results in reprograming of human B cells to express customized heavy-chain antibodies (HCAbs). HCAbs mimic a natural antibody type expressed by camelids and can be engineered with a variety of antigen-recognizing domains, including VHHs, scFvs, and other protein domains. Importantly, HCAb edited human B cells retain normal B cell functions such as clonal expansion and somatic hypermutation in response to antigen. Moreover, insertion of anti-HIV bnAb domains results in the secretion of HCAbs that neutralize a broad panel of HIV isolates. We hypothesize that such cells will be capable of long-lived engraftment and HIV control, including by providing B cell memory that could be boosted over time. To test the potential of HCAb-engineered B cells as a prevention or therapy against HIV, the next step is to adapt our editing approach for the Ig locus in rhesus macaques. These animals are useful for studies of HIV, and can be infected by either natural SIV isolates or hybrid SHIVs that substitute an HIV Envelope protein into an SIV backbone. In addition to our panel of broadly neutralizing anti-HIV HCAbs, we have now also derived novel antigen-binding domains that recognize the SIV Env. These include scFvs derived from recently identified anti-SIV bnAbs and a rationally designed variant of the receptor mimic, eCD4-Ig, that is compatible with this genome editing protocol. In parallel, we have optimized protocols necessary to isolate, activate and engineer the macaque B cells, to produce a cell product suitable for autologous transplantation. Together, these reagents and protocols are a useful toolkit for B cell engineering in rhesus macaques, and will allow us to test the ability of HCAb-edited B cells to protect against SIV/SHIV infection.

893 Preclinical Workup for an Approved Phase I/II Clinical Trial for Mucopolysaccharidosis II (MPSII): Validation of a GMP Stem Cell Gene Therapy Manufacturing Process

Stuart M. Ellison[1], Karen Buckland[2], Yuko Learmonth[1], Francisco R. Rodriguez[2], Jose B. Arago[2], Simon Jones[1], Robert Wynn[3], Claire Booth[4], Brian W. Bigger[1]

[1]University of Manchester, Manchester, United Kingdom,[2]UCL, London, United Kingdom,[3]MFT, Manchester, United Kingdom,[4]UCL Great Ormond Street Institute of Child Health, London, United Kingdom

Hematopoietic stem cell gene therapy (HSCGT) is a promising therapeutic strategy for the treatment of metabolic disorders where the central nervous system (CNS) is severely impaired. An HSCGT treatment developed for early-onset metachromatic leukodystrophy (MLD), a disease caused by mutations in the arylsulfatase-A gene, demonstrated successful outcomes in clinical trials and was recently approved for use in the UK and Europe. The HSCGT approach utilises a lentiviral vector to genetically modify patients' own stem cells *ex vivo,* introducing correct copies of a defective gene. Following transplantation back into a fully conditioned patient, these genetically modified autologous hematopoietic stem cells (HSCs) can repopulate the blood system, with a subset differentiating into myeloid cells that can traffic to the brain. Crucially, functional protein can be delivered to affected cells in both somatic organs and the central nervous system with the potential to alleviate peripheral and neurological disease symptoms and halt disease progression. We have developed a HSCGT approach for the treatment of Mucopolysaccharidosis type-II (MPSII, Hunter Syndrome), a debilitating paediatric lysosomal disorder caused by mutations in the iduronate-2-sulphatase (*IDS*) gene, leading to accumulation of heparan and dermatan sulphate which causes severe neurodegeneration, skeletal abnormalities and cardiorespiratory disease. For this application we developed a lentiviral vector that expresses human IDS fused to the blood-brain barrier crossing peptide ApoEII (LV IDS.ApoEII) to facilitate delivery of IDS to the CNS by two independent mechanisms; cell-mediated transcytosis and receptor-mediated transcytosis. In proof-of-concept (PoC) studies, HSCGT using LV IDS.ApoEII was able to normalise brain pathology and behaviour of MPSII mice, providing significantly enhanced correction compared to mice receiving HSCGT with a lentiviral vector expressing IDS only or treatment with a conventional allogeneic bone marrow transplant. Following these successful PoC studies we have been developing MPSII HSCGT for clinical application. Here we have validated a clinical stem cell transduction protocol for MPSII on peripheral blood derived human CD34+ cells, with inclusion of transduction enhancers protamine sulphate and LentiBOOST™ in order to reduce vector dose, whilst comparing and contrasting different culture conditions. Two manufacturing validation runs utilising IL-3 in the transduction media with a vector dose of MOI25 resulted in vector copy numbers of 5.09 and 6.34, and 97.1% and 98.1% cell product viability respectively. In pilot manufacturing runs with IL-3 absent from the transduction media, transduction efficiency was reduced 3-4 fold. Inclusion of IL-3 however, can initiate HSC differentiation which could potentially affect downstream cell engraftment. In two GMP pilot manufacturing runs using a vector dose of MOI100 and no IL-3, VCNs of 4.73 and 2.25 were achieved with 91.79% and 91.63% cell

product viability and high levels of human IDS activity of 1155.2 and 1511.9 μM 4-MU/4hr/μg respectively in CFU cultures seeded from the transduced cell product. Following these preclinical validations, we recently acquired MHRA regulatory approval for a phase I/II HSCGT clinical trial in MPSII patients due to start recruitment in 2023.

894 Development of a Trans-Splicing AAV Vector for the Treatment of Neurofibromatosis Type-I

Simon A. Wentworth[1], Ana Rita Batista[2], Miguel Sena-Esteves[3]

[1]Department of Neurology, Horae Gene Therapy Center, & MD/PhD Program, UMass Chan Medical School, Worcester, MA,[2]Department of Neurology & Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[3]Department of Neurology, Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA

Neurofibromatosis Type 1 (NF1) is a neurologic disease is a neurologic disease with a complex pathological burden leading to substantial cognitive and neurologic dysfunction with neuro-oncologic manifestations. As a single gene loss-of-function disorder where more than 50% manifestations are caused by sporadic mutations, NF1 is a very attractive candidate for a gene replacement type of therapy. The large size of the NF1 cDNA (~8.5 kb) is a considerable challenge for development of AAV-based gene therapies for this disease. Our laboratory has developed two AAV vector systems, a dual system with the cDNA split across two AAV genomes and a mini-NF1 gene capable of regulating Ras activity. We are developing an RNA editing using spliceosome mediated RNA trans-splicing (SMaRT) approach for NF1. SmaRT utilizes hybridization of a vector encoded mutation free mRNA, also known as a pre-trans-splicing molecule (PTM), to the endogenous mutated pre-mRNA, thereby providing the splicing machinery with alternative splice signals. The parameters that make a successful pre-trans-splicing molecule (PTM) are largely unknown, and because of that we are using a library approach to screen for the binding domains that have the greatest trans-splicing efficiency. To achieve this, we tiled 150 bp sequences by 1 nt through the adjacent 3'-intron and immediate 3'-exon corresponding to the location we wish to splice (NF1 Exon 32)(Fig. 1).

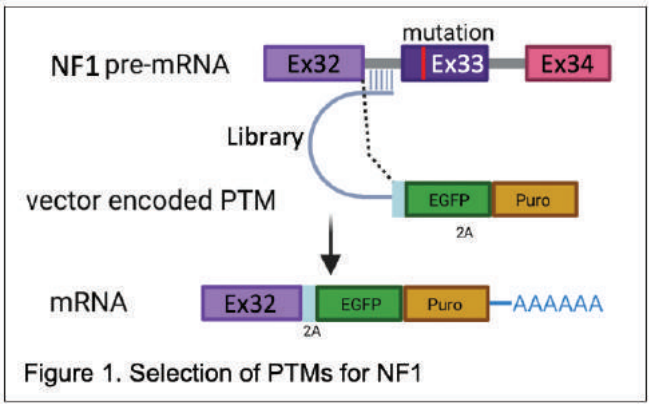


Figure 1. Selection of PTMs for NF1

This resulted in a library composed of 1,251 PTMs that could potentially enable the binding and successful trans-splicing of our vector encoded molecules to the endogenous NF1 mRNA. We designed a lentiviral vector system encoding the PTM library followed by a splice acceptor signal, and the 3' NF1 exon fused to a EGFP-Puromycin cassette via a 2A peptide to select for positive events. NGS analysis of the plasmid library indicated a 121x coverage for each PTM. Lentivirus stocks were produced and used to infect HEK293T cells, and puromycin selection started at 48hrs. Infected cells were expanded under selection for two weeks when gDNA and RNA were collected, and single clones selected for expansion and targeted analysis. Single clone analysis revealed two different inserts with clear evidence of trans-splicing from the endogenous NF1 sequence to our vector encoded sequence. NGS analysis of pooled selected cells indicated a mapping of inserts to coverage "hot-spots" within the 3'-intron indicating regions of variable strength in trans-splicing. The two inserts from single clones individually mapped to a region with high coverage and a region with low coverage. We are currently exploring the efficiency of trans-splicing with those clones as well as individual selections. Once optimal inserts are chosen, they will be encoded into vectors containing the remainder of 3' NF1 and tested in their ability to restore NF1 expression and function in NF1 patient cell lines. Eventually this work will pave the way for a semi-customized gene therapy for NF1 where patients can be given one of three vectors to only replace the portion of their NF1 which is mutated. This simplicity of design would allow for broad application of the vectors to many patients and maintaining the endogenous control of NF1 will abrogate many issues that can arise with gene dosage in similar gene replacement therapies.

895 Viral Clearance Strategies for Gene Therapy Products

Akunna Iheanacho, Jenifer Dean, Symya Chumbris, Coral Fulton, William Kerns, Daniella Ceus, Katelyn Pritchard

Texcell North America, Frederick, MD

The adeno-associated virus (AAV) is a common delivery vehicle for gene therapy products. For all biotechnology products derived from cell lines of human or animal origin, there is a risk of viral contamination from the source material or from adventitious agents during the production process. Adventitious agents, including new and emerging viruses, can be unintentionally introduced and enter a production process from different routes. It is important to assess the potential impact of adventitious agents or viruses on the safety profile of AAV gene therapies and other advanced therapy medicinal products. To ensure product safety, testing programs should take an integrated and comprehensive approach to reduce the risk of contamination across the entire manufacturing process. Developing a robust viral clearance program requires a careful assessment of risk and a thorough understanding of the manufacturing process used to develop the gene therapy product. Keeping in mind the unique properties of AAV gene therapies and other advanced therapy medicinal products, dedicated unit operations for viral clearance will typically involve virus removal or virus inactivation. Virus removal can be accomplished by chromatography or nanofiltration/virus filtration, while virus inactivation can occur via a variety of treatment methods. For gene therapy products, various chemical treatments may be utilized including the use of low pH, solvents, detergents, or a combination of solvent and detergent. Process evaluation studies were designed to test the inactivation of virus from spiked test articles

during execution of process steps. For each scaled-down process step, virus was intentionally spiked into the starting material or load, the process was performed, and the amount of virus present in samples collected at the start and end of the process was quantified. The capacity of each step for inactivation of virus was calculated and reported as the log reduction value.

896 Esophageal Cancer-Specific Gene Therapy with Liposome-Processed Oncolytic Adenovirus Introduced with SCCA1 Gene Promoter

Teruki Yamakawa, Katsuyuki Hamada, Rei Okada, Youji Kajiwara, Hideaki Shimada

School of Medicine Toho University, Ota-ku, Japan

The incidence of esophageal cancer is increasing, and the survival rate of advanced cancer is around 40-50% with no improvement in prognosis. The esophagus is an important functional organ related to daily eating and swallowing. Because of the deterioration of swallowing function due to surgery and radiation, hoarseness due to recurrent nerve paralysis, and the presence of important organs such as the heart and lungs in the surrounding organs, it is necessary to preserve the function of these organs during treatment. Gene therapy is a non-invasive treatment that can be cured by injection alone, injected endoscopically and administered multiple times. This makes it a good indication for early-stage, locally advanced and recurrent cancers. SCCA1 is expressed specifically in squamous cell carcinoma and is a good tumor marker for esophageal cancer with squamous cell carcinoma in more than 90% of cases. We cloned the SCCA1 gene promoter and was introduced into an oncolytic adenovirus AdE3-SCCA1. AdE3-SCCA1 has an antitumor effect specifically on squamous cell carcinoma, but infection is suppressed because of anti-adenovirus antibody. Therefore, oncolytic adenovirus was coated by liposome processing to overcome immunogenicity and its antitumor effect was investigated. The antitumor effect of liposome-coated AdE3-SCCA1 on murine squamous cell carcinoma SCC7 cells of C3H/HeN syngeneic mouse model was investigated. In the presence of anti-adenovirus antibodies, AdE3-SCCA1 is completely inhibited from infection, but liposome processing made it 80% infectious. Liposome-processed AdE3-SCCA1 showed no antitumor effect on SCC7 tumors in non-preimmunized mouse, but on adenovirus-preimmunized mouse, complete tumor regression was achieved against 70% of subcutaneous tumors by anti-adenoviral CTL induction. Liposome-processed oncolytic adenovirus AdE3-SCCA1 was suggested to be an effective therapy against esophageal cancer.

897 Evaluation of Affinity and Ion-Exchange Chromatography-Based Platforms for Consecutive Purification of AAV9 Vectors

Ozgun Firat Duzenli[1], George Aslanidi[1,2,3]

[1]The Hormel Institute, University of Minnesota, Austin, MN,[2]Masonic Cancer Center, University of Minnesota, Minneapolis, MN,[3]Institute Molecular Virology, University of Minnesota, Minneapolis, MN

Adeno-associated virus (AAV) vectors are leading delivery systems for pre-clinical and clinical gene therapy. However, difficulties in manufacturing including processing (host cells proteins, DNA, residual plasmid, helper virus genes, endonucleases) and product-related impurities (empty and partially full capsids, size variants, ununiform post-translational modifications, degradation) still need to be resolved. Particularly, the inefficient separation of empty capsids constitutes the vital part of an AAV preparation that pose a risk on clinical safety and effectiveness of AAV-based gene therapy. Hence, the development of selective, efficient, reproducible, scalable and cost-effective purification methods for the separation of empty capsids is vital for AAV manufacturers. Density gradient ultracentrifugation is the common and long-used method, needs to accomplish some drawbacks including time-consuming process nature, limited sample loading capacity, scalability, and the requirement for additional clarification, dialysis, ultrafiltration steps to achieve a resulting preparation with expected purity. Therefore, the use of chromatography-based methods might facilitate clinical-scale AAV production. In the current study we evaluated several affinity followed by ion-exchange chromatography-based separation platform to obtain high AAV titer and superior full to empty capsid ratio. AAV9 harboring firefly luciferase gene flanked by ITRs was produced in adherent HEK293 cells by triple transfection method. Harvested cells were disrupted by freeze-thaw cycle and cellular debris was removed by brief centrifugation. Supernatant consisting of cellular components and viral capsids was loaded on AAV9-specific AVIPure® affinity purification column. Subsequently, the eluted AAV9 capsids were divided equally and further purified by on AKTA™ chromatography system with HiTrap™ Q HP, HiTrap™ Capto™ Q and CIMmultus™ QA ion- exchange columns. BTP/$MgSO_4$ (pH 9) buffer-was used for the purification with HiTrap Q and CIMmultus™ QA columns, and BTP/$MgCl_2$/$C_2H_3NaO_2$ (pH 9) buffer was used for HiTrap™ Capto™ Q column. Step gradient elution was applied to collect enriched AAV fractions. Viral genome titer of recovered AAV vectors were quantified by qPCR, and efficiency of encapsulation was evaluated by TEM imaging. We achieved over 95% of full/empty capsid ratio and about 30 % recovery with HiTrap™ Q HP column. In contrast CIMmultus™ QA column improved both full/empty capsid ratio over than 98% and the recovery up to approximately 70% as and calculated full/empty capsid ratio on HiTrap™ Capto™ Q column was over 90% and recovery approximately 80%. Additionally, the infectivity of fractions recovered from different ion exchange columns were also evaluated by in vitro luciferase assay on HEK293 cells transduced with MOI 20,000 vg/cell. AAV-mediated luciferase activity normalized to viral titer was similar for all purified fractions. Based on the results of we concluded that electrostatic interaction between different column material and viral capsid does not have a detrimental effect AAV vectors ability to interact cellular receptors. Our preliminary data obtained from purification on three different ion exchange columns following an affinity capture indicate that tandem chromatography might be effective method to obtain high titer and high purity AAV vectors.

898 Hepatocyte Evolution During Post Natal Growth Affects Lentiviral Gene Transfer and Its Biodistribution in the Liver Lobule

Francesco Starinieri[1], Michela Milani[1], Stefano Beretta[1], Cesare Canepari[1,2], Chiara Simoni[1,2], Anna Fabiano[1], Eugenia Cammarota[3], Mauro Biffi[1], Fabio Russo[1], Ivan Merelli[1], Alessio Cantore[1,2]

[1]SR-TIGET, Milan, Italy,[2]Vita Salute San Raffaele University, Milano, Italy,[3]IRCCS San Raffaele Scientific Institute, Milan, Italy

The liver is an attractive target organ for *in vivo* gene therapy since it offers the possibility to treat metabolic and coagulation disorders. Promising pre-clinical and clinical results have been achieved in adult patients treated with adeno-associated viral (AAV) vectors, however, their use in pediatric patients is challenged by their non-integrating nature and consequent dilution of the episomal genome upon cell proliferation during liver growth. We developed lentiviral vectors (LV), which integrate into the cell genome, targeting transgene expression into hepatocytes, and achieved stable coagulation factor IX (FIX) expression in adult mice, dogs, and non-human primates. Here, we investigated efficiency of LV-based liver gene transfer in young mice, towards potential application to pediatric patients. We administered LV expressing FIX as a secreted reporter transgene to mice at different ages and observed higher FIX levels in young-treated mice (newborn or 2-week-old) compared to adult-treated mice (8-weeks-old). We isolated hepatocytes 3 days after treatment and measured a higher vector copy number (VCN) in young-treated mice compared to adults, paralleled by a lower VCN in non-parenchymal cells, particularly Kupffer cells, suggesting that lower phagocytic activity plays a role in determining a higher transgene output in young mice. Indeed, when we administered LV expressing a fluorescent reporter transgene to mice of different ages, we observed a 4-fold higher LV-positive area in the liver of young-treated mice compared to adults. Moreover, we noted non-homogeneous distribution of LV-marked hepatocytes in the liver lobule, with preferential transduction of the peri-central area in young-treated mice and peri-portal area in adult-treated mice. We then performed spatial transcriptomics of livers of young and adult mice to analyze changes in transcriptome profile that could impact hepatocyte permissiveness to LV transduction. In young mice, hepatocytes showed a peri-portal transcriptional profile, regardless of their localization in the lobule, lacking a fully established metabolic zonation. We thus hypothesized that peri-central may be less permissive to LV transduction. The proteasome pathway resulted to be more expressed in adult compared to young livers and peri-central compared to peri-portal hepatocytes. Thus, we administered the proteasome inhibitor bortezomib to adult mice before LV and achieved higher and more homogeneous liver transduction compared to LV-only treated mice, indicating that proteasome plays an important role in determining the efficiency and distribution of hepatocyte transduction by LV. Finally, we evaluated proliferation of LV-transduced and untransduced hepatocytes, by administration of EdU at different ages during growth. EdU is incorporated during DNA synthesis and allows marking of proliferating cells. We observed that 20% of hepatocytes were EdU-positive in young mice, while proliferation was almost absent in adults. We observed the same percentages also for transduced hepatocytes, indicating that only a fraction of hepatocytes proliferate during post-natal growth and LV transduction does not affect hepatocyte proliferation rate. Overall, our results indicate that LV-based liver gene therapy is more efficient in young mice, and that age of treatment impacts on LV transduction efficiency, its spatial distribution in the liver lobule and transgene output. These studies will inform further development of liver-directed LV gene therapy towards application to pediatric patients.

899 Molecular Shielding of the Pan-Hematopoietic Marker CD45 May Enable a Universal Approach for Replacement of the Hematopoietic System

Simon Garaudé[1], Romina Marone[1], Rosalba Lepore[2], Anna Devaux[1], Anna Camus[3], Izabela Durzynska[4], Eva-Maria Grossjohann[3], Andreja Knezevic[3], Christian Kunz[4], Stefanie Urlinger[3], Lukas T. Jeker[1]

[1]University of Basel and Basel University Hospital, Basel, Switzerland,[2]University of Basel and Basel University Hospital; Cimeio Therapeutics, Basel, Switzerland,[3]Cimeio Therapeutics, Basel, Switzerland,[4]Ridgeline Discovery GmbH, Basel, Switzerland

CD45-targeted surrogate antibody-drug conjugates (ADCs) enable chemotherapy-free hematopoietic stem cell transplantation (HSCT) in mice. However, the pan-hematopoietic marker CD45 is critical for the function of immune cells as illustrated by mutations underlying severe combined immunodeficiency (SCID). Therefore, CD45-targeted cell depleting therapies are currently limited to a single dose. Yet, treatment of malignancies or autoimmune diseases may require longterm therapy with CAR T cells or repeated dosing with ADCs. We recently demonstrated that single amino acid substitutions engineered into CD123 or CD117 expressed by hematopoietic stem and progenitor cells (HSPCs) protected the cells from cytotoxicity by matching immunotherapies but preserved CD123 and CD117 function, respectively. Here, we describe the identification of a CD45 shielding variant paired with the development of a new and potent CD45-targeting ADC (CIM053-ADC). To overcome limitations of homology directed repair (HDR) we aimed to install the molecular shield using base editors (BE). We computationally selected extracellular CD45 regions and screened sgRNA/base editor combinations that may generate cell shielding amino acid substitutions. We identified multiple base editable substitutions that reduced or abolished the binding to different anti-CD45 antibodies while preserving binding to control antibodies. Base edited human primary T cells were shielded from surrogate antibody-drug conjugate (ADC) killing in vitro resulting in enrichment of base edited shielded cells while wild-type cells were progressively depleted with increasing ADC concentrations. Thus, combining a shielding variant with a paired ADC resulted in a user-controlled ratio of unedited:edited cells in vitro. However, biophysical characterization of the top CD45 variant proteins revealed limitations. One CD45 candidate variant that displayed residual binding resulted in incomplete shielding while others demonstrated altered protein properties. In one case this was partially attributable to a bystander edit introduced by the BE. An expanded and optimized screen identified a lead variant which completely shielded >50% HSPCs from the binding by CIM053 while maintaining intact protein properties. Co-culture with MOLM-14 or Jurkat tumor cells (i.e. representing different cell lineages) in the presence of CIM053-ADC selectively depleted

MOLM-14/Jurkat and unedited HSPCs but left shielded HSPCs intact in vitro. Furthermore, CIM053-ADC potently depleted HSPCs in mice reconstituted with human CD34+ HSPCs while being well tolerated. Thus, we identified a base editable CD45 variant that shields from a monoclonal antibody with favorable characteristics for clinical development. The combination is ready for testing whether it enables tumor-selective posttransplant immunotherapy in mice xenografted with human HSPCs.

900 Evaluation a Novel Fluorescence-Based Approach to Sensitive Bacterial Endotoxin Testing

Alexia Bachir, Andrew Dix, Nancie Mooney, Sneh Ringwala, Jen Serafin

Thermo Fisher Scientific, Eugene, OR

Endotoxin contamination is a common problem with recombinant proteins and nucleic acids used in cell and gene therapy. These heat-stable lipopolysaccharides (LPS) are associated with the outer membranes of certain gram-negative bacteria and often introduce themselves into the experimental workflow during the lysis of plasmid DNA preparations. In cell-based experiments, contamination with endotoxin can trigger toxic shock, activation of nonspecific immune responses, or premature cell death. These effects can significantly compromise cell-based studies and skew experimental results. Current approaches to endotoxin testing primarily utilize amebocyte lysate in which an enzymatic cascade is activated in the presence of endotoxin to produce a colorimetric or turbidimetric readout. These assays are a mainstay of endotoxin detection, but often require cumbersome workflows, cost-prohibitive instrumentation, and lengthy manual data analysis. Here we describe and evaluate a novel approach to endotoxin detection which utilizes a fluorogenic reporter to improve sensitivity - offering a 0.01 - 10 EU/mL detection range with a workflow that is more streamlined than existing approaches. Furthermore, we demonstrate the impact of endotoxin contamination in a model cell study where known amounts of endotoxin with a GFP encoding plasmid are titrated into primary cells. The results highlight the effects of increasing endotoxin levels on transfection efficiency, cell line morphology, and overall cell health.

902 A Robust and Scalable Research Grade Platform Process for AAV6 Production and Purification

Shona C. Robinson[1], James Fasano[1], Matthew Marcel Guilleman[2], Lisa Santry[1], Cherylene Plewa[1], Daniel Kennedy[1], Theresa Dao[1], Jay Cai[1], Azam Hassaninasab[1], Bojiao Yin[1], Mercedes Segura[1], Stacie Seidel[1]

[1]ElevateBio, Waltham, MA,[2]Sanofi Pasteur, North York, ON, Canada

The field of gene therapy using adeno associated virus (AAV) is making significant strides as a novel therapeutic with the potential to treat and cure monogenetic disorders. AAV can be engineered to deliver long-term transgene expression cassettes to target cells, with low risk of integration and pathogenicity. With hundreds of clinical trials underway, there is a clear need for robust, scalable, and cost-effective platforms to generate research-grade material for proof-of-concept work that is more closely representative of process development platform material. We describe here a platform process for AAV6 production using a transient triple transfection, helper-free system, with serum-free suspension cells, followed by affinity resin purification using a batch method. Using an AAV transfer vector containing a 4.7kb insert comprising a representative gene knock-in cassette, we were able to achieve titers around 1E11 VG/mL for crude production and a 60% yield after affinity batch purification in our research grade platform. Both the upstream AAV6 production and downstream affinity resin batch purification align very closely with our larger scale process development platform. This allows for faster, quicker transition from research to development projects. AAV6 vector preps made with both research grade and process development show comparable transduction efficiency on HeLa cells with >90% and >50% in B cells 48 hours post transduction, at MOIs as low as 5e4 (VG/cell). No overt signs of toxicity were observed at MOIs as high as 5e5. This process will allow for an easy transition from research to process development teams for GMP manufacturing purposes.

903 An Engineered Beta-galactosidase with Improved Stability and Cross-Correction for the Potential Treatment of GM1 Gangliosidosis

Ouma Onguka[1], Jacob Artz[1], Christopher Schmitt[1], Oluwayomi Akinkugbe[1], Elizabeth Del Greco[1], Grace Lee[1], Kahsay Gebretsadik[1], Nikki Kruse[2], Chinping Chng[1], William Casey Hallows[2], Hassibullah Akeefe[1], Adam Silverman[3]

[1]Codexis, Redwood City, CA,[2]Codexis, San Carlos, CA,[3]Codexis, Inc., San Carlos, CA

GM1 gangliosidosis is an autosomal recessive deficiency of β-galactosidase (β-gal) characterized biochemically by the accumulation of GM1 ganglioside and its asialo derivative GA1 in the central nervous system. Accumulation of gangliosides and glycosaminoglycans (GAGs) leads to the progressive loss of neurons in the brain and spinal cord with concomitant peripheral tissue pathologies. No therapy is currently available for this lysosomal storage disease, and lethal by age 3 in the most severe early-onset cases. While gene therapy delivering *GLB1* to the central nervous system offers potential to slow or halt disease progression and potentially correct harmful phenotypes in patients, intrinsic limitations of the wild-type β-gal enzyme may limit the effectiveness of this approach. For example, while cross-correction of un-transduced neighboring cells and deep brain structures is required to broadly rescue storage deficits in the CNS, β-gal rapidly and irreversibly degrades at neutral pH and in body fluids. To address these limitations, we applied the CodeEvolver® protein engineering platform to screen >10,000 β-gal variants over five rounds of iterative directed evolution. The most promising β-gal variants identified are ≥20-fold more stable than wild-type β-gal in serum and artificial cerebrosidal fluid (CSF). We demonstrate that the engineered β-gal variants are taken up by and exhibit activity in GM1 gangliosidosis patient fibroblasts and human iPSC-derived GM1 gangliosidosis forebrain neurons at ≥10-fold over wild-type β-gal, potentially enabling better cross-correction capacity. This increase in stability and cellular uptake does not impact neuraminidase activity, suggesting a lack of enzymatic over-correction. Finally, we show data on the delivery of the engineered β-gal transgenes in AAV9 to GM1 ex vivo cellular disease

models and to GM1 gangliosidosis mice. Collectively, these data show the promise of an optimized β-gal transgene as a potential gene therapy for treating patients suffering from this devastating disease. **Keywords:** GM1 gangliosidosis, protein engineering, directed evolution, lysosomal storage disease, gene therapy

904 Development of Capsid + Genome-Modified Optimized (Opt^{Y}) AAVrh74 Vectors with Improved Transgene Expression in Mouse Skeletal Muscles Following Systemic Administration *In Vivo*

Jakob Shoti[1], Keyun Qing[1], Geoffrey D. Keeler[2], Dongsheng Duan[3], Barry J. Byrne[1], Arun Srivastava[4]

[1]University of Florida, Gainesville, FL,[2]University of Florida, Gainesvile, FL,[3]University of Missouri School of Medicine, Columbia, MO,[4]University of Florida College of Medicine, Gainesville, FL

We have previously reported that capsid-modified next genaeration triple-mutant (TM) AAVrh74 vectors, in which surface-exposed tyrosine (Y733 and Y447) and threonine (T494) were mutagenized, transduced primary human skeletal muscle cells more efficiently than the wild-type (WT) AAVrh74 vectors *in vitro* (*Mol. Ther.*, 29: 159-160, 2021). Similarly, we have also reported that genome-modified generation Y (GenY) AAVrh74 vectors, in which the distal 10-nts in the D-sequence were replaced with the 15-nts consensus glucocorticoid response element (GRE) site, transduced primary human skeletal muscle cells more efficiently than the WT AAVrh74 vectors *in vitro* (*Mol. Ther.*, 30: 237-238, 2022). In the current studies, we evaluated whether the combination of the two, resulting in optimized (Opt^{Y}) AAVrh74 vectors, would lead to an additive effect. GenY genomes were packaged into TM capsids to generate Opt^{Y} AAVrh74 vectors, and the transduction efficiency of these vectors was evaluated in mouse gastrocnemius (GA) and tibialis anterior (TA) muscles following systemic delivery in C57BL/6 mice (N=6 each). Transgene expression was evaluated 8 weeks post-injections. These results, shown in **Figure 1A**, indicate that compared with the TM vectors, transgene expression from the Opt^{Y} vectors, both in TA and GA muscles, was higher (**Figure 1B**). We also evaluated the extent of the transgene expression in mouse liver, heart, diaphragm, and GA and TA muscles at the RNA level. The Delta-Delta analysis, relative to the PBS control (**Figure 1C**) and to the TM AAVrh74 vector control (**Figure 1D**), indicate that the extent of the transgene expression from the Opt^{Y} AAVrh74 vectors was significantly higher in each of the muscle tissues, but not in the liver. Taken together, these studies suggest that the combined use of the capsid-modified NextGen + genome-modified GenY (Opt^{Y}) AAVrh74 vectors may further reduce the need for high vector doses currently in use, which has significant implications in the potential use of Opt^{Y} AAVrh74 vectors in the safe and effective gene therapy of muscular dystrophies in humans. This research was supported by a sponsored research grant from Sarepta Therapeutics.

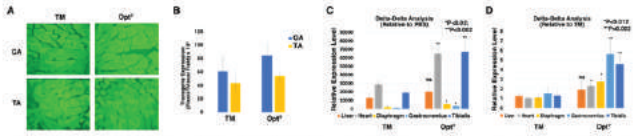

Figure 1: Transduction efficiency of TM and Opt^{Y} AAVrh74 vectors in primary murine muscles *in vivo*. A. Each vector was injected intravenously at 1x10^{12} vgs/mouse and transgene expression in tibialis anterior (TA) and gastrocnemius (GA) skeletal muscle sections was visualized under a fluorescence microscope 8-weeks post-injections. **B.** Data were quantitated using the ImageJ software. Total RNA samples isolated from various organs were subjected to RT-PCR-qPCR and analyzed by ΔCt = (hrGFP Ct – β-actin Ct) respective average WT-AAVrh74 ΔCt and reported as relative expression level or $2^{-\Delta\Delta CT}$ relative to PBS (**C**) and to TM-AAVrh74 vectors (**D**), respectively.

905 Novel Adenoviral Vectors for Gene Therapy Approaches to Treat Cerebellar Disorders

Emre Kul, Uchechi Okoroafor, Amanda Dougherty, Lauren Palkovic, Hao Li, Paula Valiño Ramos, Samuel M. Young

Anatomy & Cell Biology, University of Iowa, Iowa City, IA

Genetic variations are major risk factors for a multitude of cerebellar disorders, which can manifest in tissue-wide or cell type-specific dysfunction and degeneration. Cerebellar disorders are largely due to mutations in genes that particularly affect Purkinje cells (PCs), which are the neurons that mediate the sole output of all motor information processing in the cerebellar cortex. Due to the monogenic nature of CACNA1A disorders and Ataxia Telangiectasia (A-T), they are ideal candidates of cerebellar disorders to treat with viral vector gene therapy approaches. However, the cDNA size of the underlying *CACNA1A* and *ATM* genes exceed the packaging limits of AAV and Lentiviral vectors (LV). Therefore, non-toxic viral vectors with large carrying capacities capable of long-term stable transgene expression in PCs are needed. Helper-dependent Adenoviral vectors (HdAd) are safe, high-capacity vectors that overcome the packaging limitations of AAV and LV. Currently, the most common Adenoviral vectors are of serotype 5 (Ad5) and infect cells via Coxsackie-Adenovirus Receptor (CAR). However, PCs are refractory to CAR-dependent Ad5 infection. To overcome the limitation of Ad5, we developed Ad vector variants that use an alternative human receptor. We characterized these vectors in the cerebellum of a humanized mouse model and identified variants with tropism for PCs and other cerebellar cell types. The development of these vectors greatly expands the utility of the HdAd platform for treating CACNA1A disorders, A-T, and other disorders that will require expression of genes or transgene cassettes exceeding the capacities of AAV or LV. Finally, we propose that our vectors will have immediate translational applicability to humans for cerebellar and other Central Nervous System disorders.

906 Evaluation of a Scalable Harvest Protocol Using a Panel of AAV Serotypes with Attention to Recombinant AAV Vector Integrity and Functionality

Kimchi A. Strasser[1], Igor Alves Mancilla[1], Sonja Aichner[1], Helena Meyer-Berg[2], Georg Huber[1], Jana Bauer[1], Irene Ferreira[2], Michael Salomon[1]

[1]Process Development Department, SIRION BIOTECH (a PerkinElmer Company), Munich, Germany,[2]Cell & Gene Therapy Clinical Support Department, SIRION BIOTECH (a PerkinElmer Company), Munich, Germany

To date recombinant adeno-associated viral vectors (rAAV) have delivered functional gene copies in over 200 clinical trials and are the drug substance in five FDA or EMA approved products. There is a continued effort to design more efficacious rAAV vectors, aiming to e.g., reduce vector doses. However, several indications require systemic administration at currently still high rAAV vector doses, making rAAV manufacturing and upscaling paramount to continue rAAV's success story. Here, we aim to evaluate a more scalable harvest protocol, compared with our current standard protocol and its impact on vector integrity as well as functionality on various capsids. The rAAV vectors rAAV1-9 and rAAV-PhP.eB were produced at 30 ml scale in the AAV-MAX suspension cell system. For triple transfection, the same rAAV transfer plasmid (pAAV-CMV-EGFP) and adenoviral helper plasmids were used, as well as analogously built Rep/Cap plasmids. Subsequently, each production was either subjected to the scalable or the standard harvest protocol (n=3). The scalable protocol uses the AAV-MAX lysis buffer (ThermoFisher) which can be added directly to the cell suspension for lysis. In the standard protocol, the cell suspension is spun down and the cell pellet is lysed, while the rAAV from the supernatant is precipitated. The resulting crude lysates were analysed for vector genome (VG) titers using qPCR targeting the ITRs, with free-ITR standard curve and ATCC's AAV2 reference standard material as control. The scalable harvest protocol resulted in titers in the 6.6E11-1.1E12 VG/ml range and the standard protocol in the 4.6E11-1.9E12 VG/ml range. Comparing across vectors, the scalable harvest protocol led to lower crude lysate titers compared with the standard protocol (mean decrease 22 %, SD 9.2 %), except for rAAV4 where the scalable protocol led to increased titers. For further quality control, crude lysate triplicates from the scalable harvest protocol were purified using the POROS GoPure AAVX/9 affinity chromatography column. To determine the recovery after affinity chromatography (n=3), the elution was titrated as described above. Vectors with AAV serotypes 2, 3, 5 and 8 achieved high recovery levels (mean recovery>80 %), serotypes AAV1, AAV6 and PhP.eB achieved medium recovery levels (60<mean recovery<80 %) and AAV4's recovery rate was low with 42 %. Next, vectors were analysed for empty/full capsid ratio using the Stunner Instrument (Unchained Labs, n=3). The serotypes AAV2, 5, 8, and PhP.eB showed lower levels of full capsids (11-18 %), whereas the serotypes 1, 3, 4, 6 and 9 had a high proportion of full capsids (30-55 %) which was an evaluation of upstream process (USP) packaging efficiency. The capsid aggregation was measured in PBS buffer using dynamic light scattering (Stunner instrument, Unchained Labs, n=3). Aggregation was lower than 2 % for all serotypes, except AAV6 and AAV2. The observed empty/full ratios as well as the aggregation levels matched previous experience. We concluded that the scalable harvest protocol resulted in lower USP vector yields but achieved comparable vector quality. Taking the ease of upscaling into account, the USP yields in the scalable protocol are deemed an acceptable first result. Further optimisations are underway to increase USP yields. To test the impact on vector functionality, the next step is comparing a panel of vectors either harvested with the standard or scalable harvest protocol in an *in vitro* assay. The learnings from these process optimizations have the ultimate aim to inform rAAV vector production for large scale clinical applications in a cost-effective fashion.

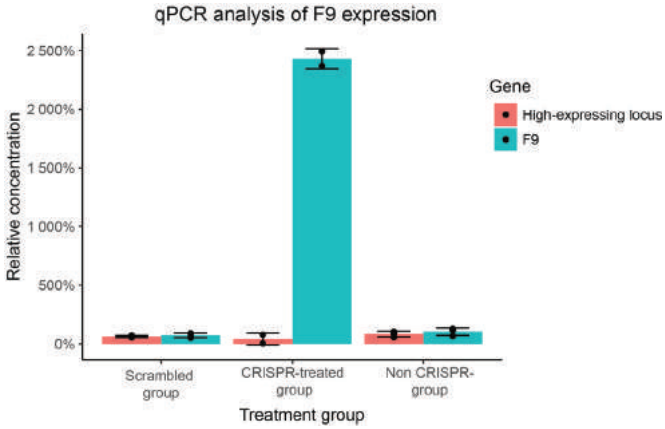
907 Targeted Genome Integration in a Novel Muscle-Specific Safe-Harbor Site Enabling High Transgene Expression

Made Harumi Padmaswari[1], Mary S. Jia[2], Shilpi Agrawal[3], Abbey Bryan[3], Gabrielle Bulliard[4], Christopher E. Nelson[4]

[1]Cell and Molecular Biology, University of Arkansas, Fayetteville, AR,[2]Biomedical Engineering, University of Arkansas, Fayetteville, Fayetteville, AR,[3]Biomedical Engineering, University of Arkansas, Fayettevile, AR,[4]Biomedical Engineering, University of Arkansas, Fayetteville, AR

Targeted integration has emerged as a gene editing technique to treat a broad range of genetic diseases and expand therapeutic options of synthetic biology. Despite substantial progress made in targeted gene delivery methods, identifying safe loci to insert replacement genes for optimal safety and efficiency remains a challenge. Gene editing approaches often target the disease locus itself; however, the proportion of successfully integrated genes may not produce the protein levels needed to alleviate the phenotype, and semi-random viral-mediated integration could lead to mutagenesis. An exciting alternative would be to identify a safe-harbor locus with high transcriptional activity. This research aims to investigate new potential sites that can be used for safe and stable integration. Here, we proposed and validated a high-expressing locus in skeletal muscle as a target site to insert a promoterless reporter gene or human factor 9. We co-delivered CRISPR-Cas9 and a homology-independent targeted integration (HITI) donor insert plasmid with a panel of candidate splice sites to hijack the endogenous promoter of muscle-specific loci in myoblasts. As a proof of concept, in our early validation with lipid nanoparticle delivery, we achieved precise in-frame integration of green fluorescent protein (GFP) and human factor 9 in mouse DNA and mRNA by genotyping the targeted site in mouse myoblast cells using primers spanning the junctions between the 5' end of the integration site and the 3' end of the insert. We also demonstrated the precision of integration of GFP at 60% at the DNA level and up to 96% at the mRNA level using Illumina next-generation sequencing. This result indicates that integration at intronic regions reduces unintended modifications during transcription and translation. To further investigate the precision of integration, we performed a high throughput short- and long-read sequencing using a unique molecular identifier-tagged library to eliminate the bias of PCR-enriched quantification efficiency. At the RNA level, the integration of human factor 9 in the muscle-specific locus showed an increase of relative expression up to 2,500-fold compared to scrambled gRNA and non-CRISPR treated group in mouse myotubes by qRT-PCR analysis (Figure 1). Additionally, a series of our studies are aimed at characterizing gene integration

safety and therapeutic efficacy in mouse models. Furthermore, global transcriptome changes are assessed by RNA sequencing. By integrating a therapeutic gene under an endogenous muscle-specific promoter, this strategy offers a safer route of administration and high expression of therapeutically relevant proteins in circulation. This approach also provides a promising framework for advancing mutation-independent gene therapy and a platform for *in vivo* synthetic biology.



908 Delivering Genes to the Brain Endothelium to Treat Lysosomal Storage Disorder-Derived Neuropathology

Nuria Roxana Romero Navarrete, Jason Wu, Thomas Beddow, Benjamin E. Deverman

Broad Institute of MIT and Harvard, Cambridge, MA

Lysosomal storage disorders (LSDs) are genetic diseases characterized by the absence of functional lysosomal enzymes or transporters. The ensuing accumulation of lipids, glycosaminoglycans (GAGs) or glycoproteins results in damage to cells and tissues such as the central nervous system (CNS), which can lead to cognitive impairment and premature death. Enzyme-replacement therapy is the standard of care for many LSDs but the inability of recombinant enzymes to cross the blood-brain barrier (BBB) remains a significant challenge. We propose AAV-mediated gene expression in the brain endothelium as a strategy to address neurological LSDs through the phenomenon of cross-correction, in which transduced cells secrete enzymes that are endocytosed by non-transduced cells. We sought to express human iduronate-2-sulfatase (hIDS) in the brain endothelium of a mouse model of Mucopolysaccharidosis type II (MPSII, Hunter's syndrome) to enable enzyme secretion into the brain parenchyma. In this disorder, IDS deficiency results in the accumulation of heparan and dermatan sulfate GAGs. We used AAV-BI30, an AAV9-derived capsid that has an enhanced *in vivo* tropism specific to the endothelium in the rodent CNS and can transduce human brain vascular endothelial cells *in vitro* more efficiently than AAV9. We show that systemic delivery of AAV-BI30:hIDS restored IDS enzyme activity in the brain, liver, and serum of IDS-KO mice and reduced GAG accumulation in the brain (Fig. 1). The cross-correction was not observed when using the AAV-BI30 vector expressing a non-secreting version of hIDS. These findings highlight that targeting the CNS endothelium is a promising approach for delivering enzymes across the BBB and restoring lysosomal metabolism.

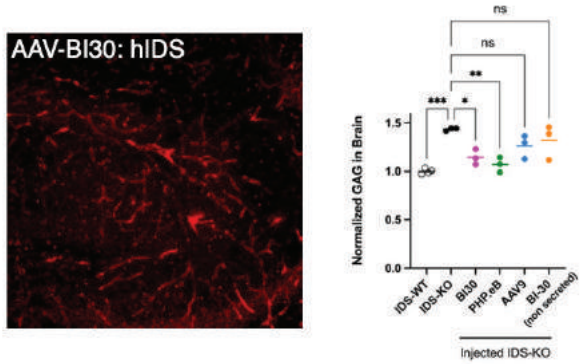


Figure 1. Systemic administration of AAV-BI30:hIDS leads to reliable expression of hIDS by the brain vasculature and corrects pathological glycosaminoglycan accumulation in IDS-deficient mice. (***Left***) Adult C57BL/6J mice received intravenous administration of 1 x 10^{11} vg/animal AAV-BI30:hIDS. Consistent with the known AAV-BI30 tropism, hIDS was expressed primarily in endothelial cells in the CNS. (***Right***) Glycosaminoglycan (GAG) content in the brains of 8- to 11-week-old wild type (WT) and IDS-knockout (KO) mice was quantified four weeks after intravenous treatment with 3 x 10^{11} vg/animal of therapeutic vectors. The results are normalized to the IDS-WT control. Lines represent the mean.

909 Biodistribution of Engineered ARRDC1-Mediated Microvesicles for Delivery of Intracellular Payloads *In Vivo*

Shu-Lin Liu, Yashodhan Chinchore, Ryan von Kleeck, Carson Semple, Lucy (Yumei) Sun, Pearl Moharil, Qiyu Wang, Komal Vyas, Kristin Luther, Adam Francoeur, Leah Gens, Alysia Bryant, Joseph Nabhan

Vesigen Therapeutics, Cambridge, MA

Limited avenues are currently presented for the safe and specific *in vivo* delivery of large and potentially therapeutic molecules. We engineered a class of human vesicles called ARMMs (ARRDC1 Mediated Microvesicles) to enable delivery of a wide range of payloads including RNA, proteins and gene editing protein/RNA complexes (Cas9/gRNA). To determine the identity of cell types amenable to transfection by ARMMs *in vivo*, we initially injected ARMMs loaded with GFP or mCherry as fluorescent reporter payloads through multiple routes of administration: Intravenous (IV), intranasal (IN), intratracheal (IT) or subretinal (SR) injection. To demonstrate the functional delivery of payloads by ARMMs *in vivo* we utilized Cre reporter mouse models. We injected ARMMs loaded with Cre protein in appropriate reporter mouse lines, Ai9 and Ai14, through multiple routes of administration as previously noted. Delivery of a reporter protein or Cre, leading to activation of tdTomato expression in target cells, was utilized to identify specific tissues and cell types that can be efficiently transfected by ARMMs. We use a combination of immunofluorescence staining and flow cytometry to generate the biodistribution profile of engineered ARMMs *vis-à-vis* the route of administration. This dataset enables the articulation of high confidence in rationale therapeutic strategies enabled by ARMMs as a delivery vehicle.

910 Heat Stress on Baculovirus Infected SF+ Cells May Lead to Product Loss

Robin Mailhot, Pratiksha Rai, Aiden Hawkins, Sandra Bennun

Process Development, uniQure, Lexington, MA

A platform process has been developed for production of adeno-associated virus (AAV) product using baculovirus infected SF+ cells. This study highlights the impact of bioreactor temperature on subsequent filtration efficiency. In this study, the production of AAV was done at three different temperatures in the bioreactor. The results showed visual differences as well as turbidity differences among temperature conditions. Extra bands were seen on protein gels on the higher temperature conditions while the intensity of other bands noticeably decreased. It was concluded that temperature post infection can play a significant impact on titer and product characteristics.

911 Gene Therapy Targeting Sphingolipid Metabolism for the Treatment of Pulmonary Hypertension

Michael G. Katz[1], Yoav Hadas[1], Adam Vincek[1], Dan Ohad[2], Smadar Tal[2], Nataly Shtraizent[3], Efrat Eliyahu[1]

[1]Icahn School of Medicine at Mount Sinai, New York, NY,[2]Hebrew University of Jerusalem, Jerusalem, Israel,[3]Gromit Therapeutics Inc, Closter, NJ

Up-regulation of ceramides in pulmonary hypertension (PH), contributes to perturbations in sphingolipid homeostasis and the transition of cells to a senescence state. We assessed the safety, feasibility, and efficiency of acid ceramidase gene transfer in a rodent PH model. A model of PH was created by the combination of left pneumonectomy and injection of Sugen toxin. MRI and right heart catheterization confirmed the development of PH. Rats were subjected to intratracheal administration of a synthetic adeno-associated viral vector (Anc80L65) carrying the acid ceramidase gene (Anc80L65.AC), an empty capsid vector, or saline. Therapeutic efficacy was evaluated 8 weeks after gene delivery. Hemodynamic assessment four weeks after the PH model creation demonstrated an increase in the mean pulmonary artery pressure, which was consistent with the definition of PH. We documented a significant increase in pulmonary vascular resistance in the saline-treated and empty capsid groups, but not in rats receiving Anc80L65.AC. Histology confirmed the right ventricular hypertrophy only in PH, saline-treated, and Anc80.Null groups. AC treatment significantly decreased the fibrosis. There was a statistically significant difference between the percentage of remodeled vessels between the PH and AC groups. Immunohistochemical analysis of small pulmonary arteries demonstrated vascular thickening and remodeling at eight weeks. Statistically significant differences were presented in the percentage of occluded vessels and medial wall thickness between Anc80. Null, and Anc80.AC groups. After Anc80L65.AC. delivery, a significant decrease in pro-inflammatory factors, interleukins, and senescence markers was observed. Gene delivery of acid ceramidase provided tropism to pulmonary tissue and ameliorated vascular remodeling with right ventricular dysfunction in pulmonary arterial hypertension. Here we demonstrated the feasibility, efficiency, and safety of airway distribution and transduction of aerosolized Anc80L65. AC is a gene therapy for the pulmonary vessels. In this study, AC overexpression improved cardiopulmonary hemodynamics and RV parameters in rodents' PH models. Sphingolipids metabolism pathways represent the main frontiers in the study of molecular cardiology. Gene transfer via intra-tracheal administration of AC can balance the physiological level of ceramide, provide tropism to the pulmonary tissue, and ameliorate vascular remodeling. Combining Anc80L65 technology with AC gene cassette offers a disease-modifying and robust solution for PH patients.

912 Characterization of Preclinical Models for Oncolytic Adenoviruses

Margarita V. Romanenko[1], Sacha Robert[1], Kazuho Inoko[1], Kari Jacobsen[1], Melanie Graham[1], John P. Carney[1], Benjamin Gelfand[2], Richard W. Bianco[1], Julia Davydova[1]

[1]University of Minnesota, Minneapolis, MN,[2]University of Wisconsin-Madison, Madison, WI

Oncolytic adenoviruses (OAds) are powerful tools in cancer treatment as they can selectively infect and lyse targeted cancer cells sparing the normal tissues. Importantly, OAds are able to activate antitumor immune responses through the induction of immunogenic cell death and interference with the immunosuppressive tumor microenvironment. Moreover, upon intravenous delivery, OAds can potentially reach distant metastatic sites allowing to perform the systemic treatment. However, the clinical development of OAds has been hampered by the lack of reliable animal models that can predict the therapeutic and immunomodulatory responses of OAds, especially those injected systemically. For the comprehensive evaluation of systemically administrated OAds, the animal models should have the following characteristics: 1) they should support OAd replication, 2) they should be immunocompetent to represent OAd-induced immune response. Third, the interaction of OAds with various blood cells and factors should resemble that in humans. However, the rodent models currently used for OAds assessment do not meet these criteria. Mice do not support replication of all human adenoviruses (Ads) which results in the lack of functional progenies. Moreover, none of the existing rodent models (including mice, Syrian hamsters, and cotton rats) are suitable for the evaluation of species B Ads, (i.e., Ad3, Ad11, Ad 35) since rodent cells lack CD46 and human desmoglein-2, DSG2, receptors. The same is true for the broadly used chimeric OAd vectors retargeted to species B Ads receptors (i.e., Ad5/3, Ad5/35). In this study, in response to the recent NIH Reproducibility Initiative, we aim to seek new and characterize the existing preclinical models for OAds evaluation. We have recently demonstrated that porcine cells and tissues can efficiently support the replication of both species B and C OAds at a level similar to human tissues. Here, we compare these findings with other models evaluating the binding, transduction, and replication efficacy of group B and C OAds (Ad5, Ad6, Ad3, Ad5/3) in various mammalian models including mice, hamsters, rats, dogs, and non-human primates. To better evaluate the OAds performance after systemic delivery, we have investigated its interaction with blood factor X (FX). Adding porcine FX to CHO cells (Chinese hamster ovary cells known to lack CAR, DSG2, and CD46 receptors) significantly increased the binding ability of both Ad5 and Ad5/3 vectors at levels similar to human FX. Additionally, we are analyzing the hemagglutination ability of Ad types toward red blood cells (RBCs) of different mammals. Our preliminary data suggest that porcine and mice RBCs do not

hemagglutinate in the presence of Ad5 and Ad5/3, while human RBCs demonstrate the ability to agglutinate in the presence of Ad5 but not Ad5/3. We anticipate these studies will provide important knowledge to assess the therapeutic, immunomodulatory, and safety profiles of OAds.

913 Small Molecule Epigenetic Modulators for Ex Vivo Expansion of Human Hematopoietic Stem Cells

Seyedeh Parisa Tajer, Kirsten Cante-Barrett, B.a.e Naber, A.a Vloemans, M.c.j.a Van Eggermond, K. Pike-Overzet, Frank Staal

Leiden University Medical Center, Leiden, Netherlands

Expansion of hematopoietic stem cells (HSCs) for therapeutic purposes has been a "holy grail" in the gene therapy field for many years. Different expansion protocols have been tested in clinical trials, but only moderate *ex vivo* expansion of HSCs has been achieved. Here, we aimed to find optimal protocols for *ex vivo* expansion of HSCs under serum-free conditions using epigenetic regulators such as CPI203 and Quisinostat. We used human cord blood HSPCs ($CD34^+$) as a source of HSC.Since $CD34^+$ is a heterogenous population, advanced flow-cytometry was used to characterize and compare the composition of stem cells and multipotent progenitors. Both *ex vivo* and *in vivo* results suggest a positive role of CPI203 and Quisinostat on *ex vivo* expansion of HSCs and negative effect of IL3 during *ex vivo* culture of human cord blood HSCs. Clinical implementation of these findings is crucial to eventually boost HSC based gene- and cell-based therapies.

914 Chemically Defined and High-Yield AAV Vector Production Medium for Suspension HEK293 Based Cell Lines

Toshikazu Nishie[1], Kaho Takeichi[1], Kumiko Uemura[1], Shuhei Sakamoto[2], Toshiyuki Miura[1], Daishi Ishihara[2], Hideto Chono[2], Sachiko Okamoto[1], Tatsuji Enoki[1], Junichi Mineno[1]

[1]Technology Development Center, Takara Bio Inc., Kusatsu, Shiga, Japan,[2]Process Development Center, Takara Bio Inc., Kusatsu, Shiga, Japan

Introduction: Recombinant adeno-associated virus vectors (rAAV) have been widely used as vehicles to deliver gene of interest for basic research or clinical and pre-clinical study of gene therapy. One of the issues to use rAAV vectors for gene therapy is large scale manufacturing. In this regard, suspension culture system using HEK293 based cell lines is highly attractive due to its scalability. Here, we describe our novel high-yield rAAV vector production medium for suspension culture which is chemically defined, serum-free, protein-free and animal origin-free. **Methods:** Viral Production Cells (VPC), Viral Production Cells 2.0 (VPC2) (Thermo Fisher Scientific), and FreeStyle™ 293-F Cells(GIBCO) were used for evaluation of the high-yield rAAV vector production medium. Cell proliferation capacity, cell survival and cell density were tested using the cells conditioned with the medium prior to use in the experiments. The rAAVs produced by transient transfection were extracted by AAV Extraction Solution (AAVpro® Cell & Sup. Purification Kit Maxi,Takara Bio), and the viral genomic copy numbers were measured by the quantitative PCR using AAVpro® Titration Kit (for Real Time PCR) Ver.2 (Takara Bio). **Results:** The newly developed high-yield rAAV vector production medium could support cell proliferation of 3 different HEK293 based suspension cell lines. The cell proliferation capacities cultured in the novel medium were comparable to those cultured in the commercially available medium. The cell densities were reached to 8 - 10 x 10^6 cells/ml when the cells were kept in culture for 7 days. In addition, more than 1 x 10^{13} viral genomic copy number/l of rAAV2 were obtained from the cells cultured in the novel medium and the rAAV production efficiencies were 20 - 50 % higher than those in the commercially available medium. **Discussion:** These results show that our novel high-yield rAAV vector production medium can be optimal and useful for large scale manufacturing of rAAV in suspension culture system.

915 rAAV-Delivered Hepatocyte-Specific Expression of miR-375 Protects Against the Acetaminophen-Induced Acute Liver Failure in Mice

Jinghua Liu[1], Yi Wang[2], Guangping Gao[1], Jun Xie[1]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Department of Pathophysiology, Sichuan University, Chengdu, China

Acetaminophen (APAP) overdose is the leading cause of acute liver failure (ALF) in many countries, including the United States. The high incidence of mortality associated with APAP-ALF can be attributed to its rapid onset. N-acetylcysteine (NAC) treatment, though effective, is time limited. Beyond ten hours after an over-dose, the liver cannot be rescued. Many studies have shown that various microRNAs (miR) can serve as potential biomarkers or therapeutic targets. Among these microRNAs, miR-375 levels correlate with the severity of APAP-challenge significantly in clinical samples, which makes it an appealing target for mitigating APAP-ALF. Using AAV8 capsid and Thyroxine Binding Globulin (TBG) promoter, miR375 was expressed in hepatocytes specifically. When challenged with APAP, ALF could be completely rescued in the miR-375 treated mice compared with control group. Liver APAP metabolites were measured with LC/MS-MS, increased levels of liver-protecting Glutathione (GSH) before APAP treatment and decreased cytotoxic byproduct NAPQI (N-acetyl-p-benzoquinone imine) protein adducts after APAP challenge were observed in miR-375 expressing liver. RNA-seq analysis identified three novel targets, Slc16a2, Acls5 and Cyb5b that were downregulated by miR-375. *In vivo* silencing using artificial miRNA (amiR) against these three genes via AAV8 could protect the liver from APAP-ALF. In addition, Cyp2E1, a key enzyme which was involved in the APAP metabolism into NAPQI, was downregulated by miR-375. To investigate if Cyp2E1 inhibition by miR-375 was required for the liver protection, we used a lower dose of miR-375 without changing the level of Cyp2E1, the liver could still be protected from APAP-ALF to a less degree. Partial/Incomplete protection of APAP-ALF could also be achieved by lowering Cyp2E1 to the level of which miR-375 treatment induced using fine-tuned dose of amiR against Cyp2E1. These results implied the protection by miR-375 was not fully Cyp2E1 dependent and other factors were involved. RNA-seq experiment using livers treated with miR-375 and amiRs against Slc16a2, Acls5 and Cyb5b was carried out. It revealed that the inhibition of Cyp2E1 was accompanied by upregulation of other key enzymes such as Gstm2, Gstm3 and Sult2A7, which were involved in APAP detoxification. Over-expression studies showed that Gstm3 could protect the liver from APAP-ALF in WT

mice. Cyp2E1 heterozygous mice has been acquired and TBG-driven Gstm3 was delivered into the liver with AAV8, the results showed that APAP-ALF was well protected. Taken together, decreasing Cyp2E1 and the production of NAPQI along with increasing Gstm3 and liver glutathione were the two major pathways that miR-375 achieved the liver protection against APAP-ALF. We are exploring if miR-375 can serve as an alternative or better treatment than NAC in acetaminophen overdose and other liver diseases. **J.L. and Y.W. are co-first authors; G.G. and J.X. are co-corresponding authors.**

916 VP1 Peptide Insertions Block Anti-AAV Antibody Binding and Neutralization

Arpana Khatri[1], Marla Bazile[1], Bin Li[1], Anton Pritchard[1], Sagar Nisraiyya[1], Jatin Narula[2], Lisa R. Keyes[3], Joanne Brodfuehrer[2], Sury Somanathan[1]

[1]Rare Disease Research Unit (RDRU), Pfizer Inc, Cambridge, MA,[2]Biomedicine Design (BMD), Pfizer Inc, Cambridge, MA,[3]Biomedicine Design (BMD), Pfizer Inc, Morrisville, NC

Adeno-associated viral (AAV) vectors have been used in gene therapy clinical trials for almost two decades. First generation constructs were based on naturally occurring serotypes isolated from human or non-human sources. These naturally occurring serotypes rarely possessed all the desired attributes and often lacked the biodistribution necessary to target extra-hepatic tissues. Second generation capsids were developed to have more desirable attributes by engineering the capsid sequence. Capsid engineering by insertion of short peptides at solution exposed hyper-variable region (HVR) has provided considerable benefit in targeting multiple tissues by crossing anatomical barriers. Here, we evaluated binding and neutralization of four AAV9 engineered peptide inserted capsids (9P801, EPIC1-2, and AAV-PHP.B) by two monoclonal anti-AAV9 antibodies, ADK9 and pMAb9; a commercially available antibody and a proprietary antibody, respectively. A cell-based transduction inhibition assay or an ELISA-based assay was used to quantify neutralizing and binding antibodies, respectively. While both antibodies neutralized AAV9 capsid and prevented transduction (IC50 59.33 and 68.22 ng/mL), they had no activity against two molecularly distant AAVs (AAV3B and AAV6). Interestingly, both monoclonal antibodies also did not neutralize the four engineered capsids which differed from AAV9 only by peptide insertion in HVR VIII. Binding antibody assays confirmed these findings with both monoclonal antibodies only binding AAV9 and not the engineered capsids. Collectively, these results suggest the site of peptide insertion overlaps an antigenic site recognized by these monoclonal antibodies. Next, we compared the seroprevalence of NAb against one of the novel capsids (9P801) in healthy human donors (N=100). 9P801 seroprevalence was lower compared to AAV9 (30% vs 35%, 9P801 vs AAV9). Even among positive donors, the magnitude of neutralization was lower with nearly twice as many human donors with high titer AAV9 NAb compared to 9P801. Also, the average 9P801 NAb titers were lower by at least 38% when compared to AAV9. Similarly, in cynomolgus macaques twice as many animals had higher titer AAV9 NAbs with average 9P801 titers lower by 62%. Overall, our studies demonstrate that capsids with peptide insertions in HVR loop that overlap a potential antigenic site are less effectively bound and neutralized by antibodies that may allow dosing of patients with low level NAb over the parental capsid, while also increasing their overall safety and efficacy following systemic administration.

917 High-Throughput Genotype and Functional Analysis of CRISPR/Cas9 Edited Hematopoietic Stem and Progenitor Cells Using Single-Cell Genotyping to Transcriptome (GoT)

Mingming Cao, So Hyun Park, Gang Bao

Bioengineering, Rice University, Houston, TX

Sickle cell disease (SCD) is an inherited disorder caused by a single nucleotide substitution in the beta-globin gene (*HBB*), replacing glutamic acid with valine at the sixth residue. CRISPR/Cas9 gene editing has been proven as an efficient approach to correcting the pathogenic sickle mutation in *HBB* via the homology-directed repair (HDR) pathway after delivery of Cas9/gRNA ribonucleoprotein (RNP) complex and corrective donor template. However, genome editing-induced DNA double-stranded breaks (DSBs) can result in complex gene modifications, which could lead to detrimental phenotypes. We clonally genotyped 80 erythroid colonies differentiated from patient hematopoietic stem and progenitor cells (HSPCs) treated with R-66S RNP targeting the sickle mutation on *HBB* and single-stranded oligonucleotide (ssODN) donor. We found that 18.5% of the colonies carried large deletions (LDs), with a very diverse allelic genotype including HDR/LD (8.2%), small insertions or deletions (Indel)/LD (9.0%), and HBD gene conversion/LD (1.0%). The high rates of unintended consequences, including gene ablation, mRNA truncation, misregulation, and deleterious protein products, could significantly reduce the therapeutic effects of gene correction, and cause safety concerns. Therefore, high-throughput genotype and phenotype analysis of single cells is critical to evaluate the safety and efficiency of gene editing-based therapy. We used single-cell genotyping of transcriptome (GoT) analysis, which can track the transcript of an edited gene and its transcriptome using a shared barcode from single-cell RNA sequencing (scRNA-seq), providing a method to directly link functional consequences with a specific genotype in high throughputs. Using scRNA-seq GoT, we analyzed R-66S RNP treated, R-66S RNP+ssODN treated, and untreated SCD HSPCs at 0 days, 4 days, and 10 days after erythroid differentiation. The *HBB* mRNA-tagged cell-specific barcodes from edited and unedited cells were amplified and sequenced on MiSeq. We developed a bioinformatics pipeline to accurately identify the genotypes in edited cells with major functions such as unique molecular identifiers (UMI) consolidation and editing outcomes quantification. The transcriptome libraries were sequenced on Next-seq and were analyzed using the Seurat R package. We conducted a global analysis of the gene expression and generated cell clusters using the uniform manifold approximation and projection (UMAP) method. The genotyping results were then mapped to corresponding cells in UMAP cell plots. On 10 days post differentiation, the GoT analysis of 2,111 RNP-treated cells detected at least 289 unique genotypes, categorizing into 18 groups: homozygous (homo) SCD, homo HBD, homo LD, homo SI In, homo SI Out, heterozygous SI In/SI In, SI Out/SI Out, SI In/SI Out, SCD/SI In, SCD/SI Out, LD/SCD, LD/SI In, LD/SI Out, LI/SI Out, HBD/SCD, HBD/SI In, HBD/SI Out, and HBD/LD,

in which we defined LD as large deletion, LI as large insertion, SI In as in-frame small indel and SI Out as out-of-frame small indel. RNP-treated SCD HSPCs formed a unique cluster of cells displaying impaired erythroid maturation phenotype with a high abundance of biallelic *HBB* knockout genotype compared to the untreated sample. In summary, our GoT analysis revealed strikingly high genotypic heterogeneity in gene-edited cells at a single-cell resolution and directly linked gene editing introduced HBB genotypes to varying degrees of erythroid maturation phenotype. We will further dissect the genotype and phenotype of gene-edited cells to derive novel insights into genotypes that led to impaired phenotypes and their molecular pathway, which is critical for the accurate evaluation of biological/clinical consequences of gene editing for safe clinical translation.

918 Characterization of Exo-AAVs Produced from AAV8, 9 and 10 Serotypes

Jade V. Bose, Caroline E. Bass

Neuroscience, University of Buffalo, Buffalo, NY

Recombinant adeno-associated viruses (rAAVs) are currently being explored as treatments of several nervous system disorders. Modifications of rAAVs are being developed that help increase transduction efficiency, targeting of specific cell types (e.g., neurons or glia) and to cross the blood-brain-barrier after systemic infusions. Additionally, there is great interest in finding means of the rAAV to evade the immune system to avoid the production of neutralizing antibodies that will limit the rAAV's ability to be used multiple times. Recently it has been discovered that rAAV can exist in an exosomal associated form. These so called exo-AAV formulations have several interesting properties that can be leveraged in treating CNS disorders. For example, the exosomal envelope appears to prevent the immune system from recognizing the rAAV with little to no neutralizing antibody production to exo-AAV formulations. Further, the presence of the exosomal envelope allows us to leverage targeting strategies to create formulations of exo-AAV that are permeable to the blood brain barrier. Alternatively, targeting strategies can be used to limit transduction to specific cell types within the brain, which is critical in treating neurological disorders whose etiology is based in a specific subset of cells (e.g., dopamine neurons in Parkinson's Disease). The rise in use of rAAVs in treating CNS disorders over the past decade comes in large part from the discovery of AAV serotypes that readily transduce nervous tissue with great efficiency, including AAV8, 9 and 10. Therefore, as a critical first step in exploring the use of exo-AAVs in CNS applications, we have determined the packaging efficiency of exo-AAVs based on common rAAV serotypes used in CNS applications. In this study we have isolated exo-AAV preparations from different rAAV serotpyes using sequential centrifugation of HEK-293 cell cultures actively producing standard pseudotyped rAAVs. The culture media was centrifuged at 1000 x g followed by 20,000 x g and then 100,000 x g to isolate the exosomal fractions. The preparations were then titered, nanaoparticle sizes were analysed and the viruses were tested via transduction of various cell types. We have determined that rAAV2/8, 2/9, and 2/10 all package efficiently in exo-AAV formulations where they are produced with high titer and retain good transduction efficiency. We discuss modifications to the packaging procedure that may help optimize the production of exo-AAVs based on different serotypes.

919 Direct Comparison of Muscle Specific Promoters in Proliferating and Differentiated Myogenic Cells

Julienne Dietz[1,2], Frank Jacobsen[2], Nassam Daya[2], Heidi Zhuge[2], Wenli Zhang[1], Anja Ehrhardt[1], Matthias Vorgerd[2], Eric Ehrke-Schulz[1]

[1]Witten/Herdecke University, Witten, Germany,[2]Ruhr University, Bochum, Germany

The heterogeneity of muscular tissues complicates the development of gene therapy that would be restricted to one or equally effective in different muscle type. A promoter for muscle gene therapy should exhibit limited activity in non-targeted tissue, while conferring specific, long-term sustained and physiological expression in the desired muscle types. Several muscle specific promotors have been identified and further optimized. Several of them have proven efficiency and some are widely used throughout the research community. However, a direct comparison between different muscle specific promotors is hard to find. Here we present a direct comparison of muscle specific Desmin and MCK-based chimeric MHCK7 promoter as well as microRNA206 and Calpain3 promoter. Desmin and MHCK7 promoters are said to be highly active in murine and human skeletal muscle and in the heart, whereas microRNA206 and Calpain3 promoter where described provide gene expression mainly restricted to skeletal myocytes. Reporter gene expression mediated by the different promoters was analysed by plasmid transfection using optimized protocols ensuring similar transfection efficiencies human and murine skeletal myoblasts and cardiomyocyte precursors. Since both, the activity of human promoters and the complexity of protein related physiological processes may differ in the animal model compared to the human organism, we present an *in vitro* model based on electrical pulse stimulation (EPS) to provoke sarcomere formation in 2D cell culture for quantification of promoter activity in far differentiated mouse and human myotubes. We found that Desmin and MHCK7 promoters showed stronger reporter gene expression levels in proliferating and differentiated myogenic cell lines than miR206 and CAPN3 promoter. However, Desmin and MHCK7 promoters mediated gene expression also cardiac cells whereas miR206 and CAPN3 promoter expression was more restricted to skeletal muscle. Our study provides insights helping to choose optimal muscle specific promotors for an intended treatment approach with regard to muscle tissue specificity, expression strength and duration.

920 Optogenetic Modulation of the Spine for Pain Inhibition

Darryl Narcisse[1], Robert Benkowski[1], Ashutosh Tripathy[1], Samarendra K. Mohanty[2]

[1]Opsin Biotherapeutics, Bedford, TX,[2]Nanoscope Technologies, Dallas, TX

Introduction: Pain is a nearly universal experience with evolutionary value as a warning system for injury and illness. However, it can also be so pervasive and intense that it becomes a pathological state that impedes physical, psychological, and social function. There are many neurological structures involved in the pain experience which detect, communicate, modulate, and process pain information. The spinal cord and associated structures such as the dorsal root ganglia (DRG) communicate pain information from the peripheral nociceptors. Here, we present a red light-

activated combinatorial gene therapy approach for cell-selective modulation of neuronal circuitry in spine for pain inhibition. **Methods:** Multi-Characteristic Opsin (MCO) having high red-light sensitivity allows deeper tissue penetration (due to low scattering and absorption) while minimizing photo-toxicity. For genetically targeting the expression of MCO in inhibitory (GABAergic) neurons, Glutamic Acid Decarboxylase (GAD) promoter was used. A wireless Optogenetic Pain Modulator (OPM) device was developed to provide optogenetic stimulation with red (630 nm) light in a controlled and programmable manner through the dermis and other overlying tissues. We tested the efficacy of red light in pain modulation using acute (e.g. formalin assay, hind paw injection) and chronic (sciatic nerve constriction, SNC) pain models in mice. We measured reflexive pain responses with and without optogenetic stimulation. Pain scoring in the acute pain model was quantified by measuring the time spent performing typical pain expressions/coping actions within a 60 second span. In the chronic pain model, treatment efficacy was measured by comparing the force needed to cause paw withdrawal (an indication of sensitivity to potential mechanical pain) after chronic injury (which increases sensitivity and decreases the needed force) with and without red light stimulation. **Results:** Red light stimulation of MCO-expressing inhibitory neurons of the spine reduced both acute and chronic pain reflexive responses. Pain responses to formalin injection were significantly reduced in the second phase of the formalin challenge (which is dominated by inflammatory pain sensation). Red light stimulation also increased the threshold for mechanical allodynia in SNC mice. **Conclusion:** Our results support the hypothesis that transdermal red-light stimulation of MCO-sensitized inhibitory neurons of the spine can effectively reduce both acute and chronic pain. The use of a highly sensitive light-actuator (MCO) and the properties of the wireless-controlled OPM device allows a highly customizable cell-specific transdermal red-light stimulation for effective pain modulation with a low power burden.

921 A High-Throughput Small Molecule Screen Identifies Targets That Increase AAV9 Production in Suspension HEK293 Cells

Francis Grafton, Ryan Feitzinger, Kaylin Fisher, Lily Leveque-Eichhorn, Chris Reid, Mo Mandegar

Innovation Hub, Ascend GCTx, San Francisco, CA

The use of recombinant AAV as a vector for gene delivery is widespread, with over 900 pre-clinical and clinical programs underway. However, inefficient manufacturing methods result in high costs, limiting the availability of gene therapies. In this study we describe a high-throughput small molecule screening strategy to identify compounds that increase the capacity of cells to produce AAV9. We used the ATLAS (Arrayed Targeted Library for AAV Screening) platform to perform the primary screen using a library of over 3000 small molecules. Targets identified included transmembrane proteins, DNA repair proteins, cell-cycle regulators, and epigenetic modulators. The top 70 performing compounds were re-evaluated in a dose-response manner on our proprietary HEK293 cell line (AC001.230). After a series of studies in small and large-scale shake flasks, we identified a novel compound (SM-016) that increased rAAV9 production in a robust and dose-dependent manner. We have confirmed these findings using capsid titer and vector genome quantification using two reporter constructs. Evaluation of SM-016 is ongoing to apply these findings for production of FDA-approved therapeutic transgenes with multiple AAV serotypes and in a large-scale bioreactor system.

922 Biological Pacemaker Activity by AAV9-TBX18 Induced Somatic Reprogramming

Rodrigo Miguel Dos Santos, Thassio Mesquita, Lizbeth Sanchez, Liang Li, Eduardo Marbán, Eugenio Cingolani

Smidt Heart Institute, Cedars-Sinai Medical Center, Los Angeles, CA

Background: Sinoatrial node (SAN) dysfunction is a clinical disorder characterized by the inability of the SAN to maintain appropriate heart rates at baseline and/or during stress. Patients with this condition often need the implantation of an electronic pacemaker. Although it is the current standard of care, devices can have limitations and complications such as lack of chronotropic response, generator or leads malfunction, and infections. Creation of a biological pacemaker has been shown by gene therapy using adenovirus expressing the human transcription factor TBX18. However, adenoviruses are immunogenic, limiting the duration of transgene expression. **Aim:** We sought to induce somatic reprogramming *in vivo* and create a biological pacemaker using Adeno-associated virus serotype 9 (AAV9) expressing human TBX18. **Methods:** AAV9 containing GFP (control) or TBX18 transgenes were directly injected into the myocardium of eight-week-old male Sprague Dawley rats at low (1x109 GC), mid (1x1010 GC) and high (1x1011 GC) doses. Six weeks after intramyocardial injections, we induced atrioventricular (AV) block *in vivo* using adenosine (10 mg/kg, i.v.) while the rats were monitored by a 6-lead electrocardiogram. Hearts were harvested for optical mapping, histology, and mRNA analyses. **Results:** No electrophysiological abnormalities were noted in either of the groups at baseline. After AV block induction using adenosine, only rats injected with AAV9-TBX18 mid-dose had increased heart rate (111±5.5 vs GFP: 87±10.6 bpm, 27%, p=0.04) compared to AAV9-GFP. Further analysis of the mid-dose groups revealed no histological changes in the injection or remote sites when we compared the GFP and TBX18 groups. We quantified ectopic beats in the mid-dose injected rats and detected a higher number of ventricular ectopic beats in the AAV9-TBX18 (14±7.2 vs GFP: 2±2.0 bpm, p=0.04) group than AAV9-GFP. To verify that the origin of the ectopic beats was indeed coming from the injection site, we performed a 6-lead EKG analysis to obtain the QRS axis in the frontal plane. This revealed that the ventricular ectopic beats from the AAV9-TBX18-injected group originated from the injection site. In addition, we performed optical mapping in isolated hearts from AAV9-GFP and -TBX18 groups after *ex vivo* induction of AV block. Accordingly, activation maps confirmed that the injection site originated those beats in TBX18-injected rats only. Successful reprogramming of adult ventricular myocytes into sinoatrial node-like cells was confirmed by transcriptional profiles with increased expression of TBX18 (2.2±0.5 FC relative to GFP, p<0.0001) and Hcn2 (25.2±1.1 FC relative to GFP, p=0.02), and reduced Gja1(-10.8±0.7 FC relative to GFP, p=0.005), Scn5a (-1.1±0.8 FC relative to GFP, p=0.01) and Nkx2.5 (-2.0±0.6 FC relative to GFP, p=0.0004). **Conclusion:** Collectively, these data indicate that the AAV-based somatic reprogramming creates sustained biological pacemaker activity in rats with AV block. Long-term studies are needed to characterize the long-term effects of sustained TBX18 expression.

924 Precise Measurement of Vector Copy Number and Transduction Efficiency at Single-Cell Resolution for Cell and Gene Therapy Development

Alex Li[1], Saurabh Parikh[1], Khushali Patel[1], Yilong Yang[1], Daniel Mendoza[1], Mahir Mohiuddin[2], Hua-Jun He[2], John Elliott[2], Brittany Enzmann[1], Vanee Pho[1], Shu Wang[1], Benjamin Schroeder[1]

[1]Mission Bio, South San Francisco, CA,[2]NIST: National Institute of Standards and Technology, Gaithersburg, MD

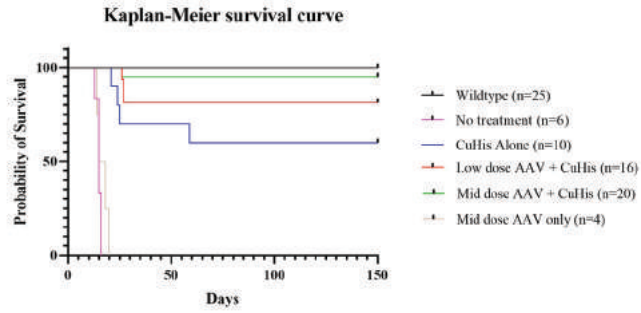
Cell and gene therapies are transformative solutions for patients with inherited and acquired diseases for which existing interventions are ineffective. The therapies target diseases at the cell level and modify or replace genes of specific sets of cells to alter their functionality. Such therapies usually rely on viral transduction or non-viral vector gene transfer techniques to introduce transgenes into host cells. The accurate measurement of gene transfer is critical to the development of therapeutic agents, which directly contributes to their safety and clinical efficacy. Currently, methods for the quantitative measurement of gene transfer lack the resolution and representation to truly reflect sample composition and either report a population bulk average or require labor intensive and time-consuming clonal isolation which can take weeks. Here, using a microfluidic, emulsion based single-cell DNA sequencing platform and a highly multiplexed amplicon panel targeting both vector sequence and human genome, we demonstrate a novel methodology that provides precise and accurate measurements of vector copy number (VCN) and transduction efficiency at single-cell resolution for cell and gene therapy development. A set of well characterized clonal cell lines with a range of known vector copy numbers validated by orthogonal methods was used for assay development. We show that single-cell DNA sequencing identifies transduced versus non-transduced cells with exceptional sensitivity (99.9%) and specificity (99.6%) with high precision. In the same assay output, populational VCN can be measured with high correlation (R squared value 0.99) compared to orthogonal ddPCR values. Due to the simultaneous measurement of transduction % and populational VCN, the assay also provides average VCN per transduced cells from the same data set. Finally, besides average VCN, the distribution of VCN at single-cell resolution can be characterized. The single-cell level vector copy number and transduction assay provides exceptional resolution and valuable insights for those developing more effective and safe therapeutic agents.

925 Dose Ranging Pre-Clinical Studies of Systemic AAV9 with Codon-Optimized Reduced Size ATP7A (cors-ATP7A) Plus Subcutaneous Copper Histidinate in a Menkes Disease Model

Lalitha Venkataraman, Tarun Kaniganti, Benjamin Kennedy, Stephen G. Kaler

Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH

Menkes Disease (MD) is an infantile onset, X-linked recessive disorder of copper transport characterized by rapidly progressive neurodegeneration, seizures, and failure to thrive caused by mutations in *ATP7A*, a copper transporter gene. The *mottled-brindled* mouse model (*mo-br*) harbors a spontaneously arisen deletion in *Atp7a*, the murine homolog, and recapitulates salient features of MD including low serum copper levels, severe neurodegeneration, and early death (postnatal day 13). We previously documented 23% & 53% rescue of this model with CSF-directed AAV5- or AAV9- mediated transfer of a reduced size (rs) version of human *ATP7A*, in combination with subcutaneous copper. Following a CBER/FDA pre-IND meeting, we completed dose-ranging pre-clinical studies of intravenous AAV9 delivering a codon-optimized, reduced size version of *ATP7A* (corsATP7A) plus 30μg clinical grade CuHis by subcutaneous injection. AAV biodistribution in a 12-day wildtype and *mo-br* mouse revealed efficient transduction in various organs except the renal medulla, reflecting inability of AAV particles to effectively traverse renal glomeruli and reach the distal nephron. Safety, efficacy, and toxicological studies identified two doses, $2.6x10^{12}$ and $2.6x10^{13}$ vg/kg body weight + CuHis as highly promising, with combined long-term survival of 89% (n=36) versus 60% in mice receiving CuHis alone (n=10) and 0% for AAV9-corsATP7A alone (Fig. 1). Overall outcomes (serum and brain copper, brain neurochemical ratios, growth, neurobehavior) appear superior in the $2.6x10^{13}$ vg/kg + 30μg CuHis cohort survivors (n=19). Administration of a higher dose, $2.6x10^{14}$ vg/kg, was initially well-tolerated, but sudden death occurred in 5 of 6 animals after CuHis administration on P4 or P5. Postmorten analyses showed no evidence of brain, or liver toxicity however acute renal tubular necrosis and high renal copper levels were noted and considered the cause of death.



While prior studies in human subjects have shown that early intervention with CuHis alone improves survival & clinical outcomes, the overall burden of disease remains considerable. Based on the multi-tasking character of *ATP7A*, Menkes disease infants identified prior to symptoms would appear to benefit from viral gene therapy that provides working copies of ATP7A. Our IND-generating studies in the *mo-br* mouse represent important steps toward a future pilot clinical trial for individuals with this illness. In combination with newborn screening for ATP7A-related disorders, the potential impact of our results on clinical practice is high since the largest barriers to good health for patients with Menkes disease would be circumvented.

926 Targeted Gene Insertion of *Factor 9* as a Potential Durable Treatment for Hemophilia B

Leah Sabin[1], Dan Chalothorn[1], KehDih Lai[1], Yong Kim[1], Rachel Sattler[1], Catherine Moroski-Erkul[2], Kathryn Walsh[2], Cindy Shaw[2], Jonathan A. Phillips[2], David Gutstein[1], Lori Morton[1], Christos Kyratsous[1]

[1]Regeneron Pharmaceuticals, Tarrytown, NY,[2]Intellia Therapeutics, Cambridge, MA

CRISPR/Cas9-mediated genome editing is an emerging approach to treat human diseases by addressing their underlying genetic cause. We have developed CRISPR-based therapeutic platforms to either reduce or restore expression of genes involved in human disease. One such platform is an *in vivo* CRISPR-based gene replacement approach, which involves the targeted insertion of a promoterless expression cassette into the *Albumin* locus of liver hepatocytes using a lipid nanoparticle (LNP) and adeno-associated virus (AAV) delivery system to allow robust and durable therapeutic protein expression from the liver. We have applied this approach to the treatment of hemophilia B, an X-linked genetic disorder characterized by reduced coagulation Factor IX (FIX) expression and impaired coagulation pathway activity. Here, we describe our CRISPR/Cas9-based targeted gene insertion platform technology and highlight how this approach provides important advantages over AAV episome-based therapies. In particular, we demonstrate that expression of FIX via insertion is durable and stable in multiple models of rapid liver growth. To aid with the clinical translation of our *Factor 9* gene insertion program, we established the optimal timing and sequence of the AAV and LNP dosing regimen in multiple model systems. Our development candidate demonstrates robust, dose-responsive human FIX expression in both rodents and primates. We have established that liver insertion-derived FIX protein is functionally indistinguishable from purified human FIX, and treatment with our development candidates rescues hemostasis in hemophilia B mice. We are developing a suite of molecular tools to further monitor and characterize insertion products at the level of DNA, RNA, and protein. Our *Factor 9* gene insertion program may represent a novel treatment for patients with hemophilia B and highlights the potential of our liver gene insertion platform technology to address a variety of indications that would benefit from durable gene replacement therapy.

927 Development and Optimization of a Feeder Cell Free TIL Therapy Platform

Brandon Haigh, Rajat Das, Cory Gariepy, Grace Massala, Cristian Abarca, Yuxiang Huang, Tatiana Golovina

WuXi Advanced Therapies, Philadelphia, PA

Tumor-infiltrating lymphocyte (TIL) Therapy, a type of adoptive cellular therapy, has garnered increasing attention across the cell and gene therapy industry over the last 40 years. Typically performed by harvesting infiltrated lymphocytes from tumors, co-culturing with feeder cell lines, amplifying or modifying, and infusing back to patients for the successful treatment of solid tumors, many groups from both academia and industry have made TIL therapy variations a focus of research and clinical trials. Unfortunately, despite encouraging results in early studies, TIL therapies continue to face challenges such as side effects coming from high-dose IL2 requirements, TIL exhaustion after long-time culturing in vitro, lack of persistence in patients, and various feeder cell challenges. As an industry leading Contract Testing Development and Manufacturing Organization (CTDMO), WuXi Advanced Therapies (WuXi ATU) is developing a feeder cell-free TIL platform aimed at enabling ongoing research and pre-clinical and clinical phase TIL based therapies. The WuXi ATU TIL Platform is a continuously developing program that focuses efforts on leveraging automated joint enzymatic and physical dissociation of tumor tissues, combined with lower dose cytokines and optimized growth parameters, media, and activators to stimulate growth of potent and healthy TIL. Originally, the platform was developed by using dissociated tumor cells (DTCs) harvested and banked from patients with carcinomas and adenocarcinomas of various origins. We were able to perform design of experiment (DoE) comparison studies to evaluate new available media, activators, and cytokines in comparison with the platform reagents for the process performance and final product quality. After establishing preferred parameters using the DTCs, development was expanded to combine our preferred parameters with fresh tumor tissue obtained from cancer patients. Conclusions: 1)TIL expansion starting from disintegrated tumors rather than from tumor fragments is a viable method for TIL therapy initiation.2)TIL growth in the absence of feeder cells is a viable option for TIL therapies.3)TIL proliferation rates and final product cell quality are impacted by basic media and supplements.4) Media type and human serum albumin (HSA) presence make a significant impact on CD4/CD8 ratio.5)Re-stimulation can help to increase TIL population doublings and yields.6)The activation method impacts CD4/CD8 ratio in the final product. We have demonstrated that lymphocytes obtained from DTCs and those harvested from tumor tissue in cancer patients expand differently in different media; we also demonstrated that the CD4 to CD8 ratios in the final products can vary considerably depending on the culture media, activators, and cytokine concentrations. Based on the results we obtained above, we will further optimize our TIL Cell Therapy Platform for successful manufacturing of cell therapies from cancer patient starting material. Ongoing studies include evaluating additional cytokines in various concentration combinations added at different critical time points, investigating re-stimulation impact, and optimizing isolation methods for purification of T cells at critical stages in the process.

928 Cell Type-Specific Genetic Therapy of Cancer, Virus Infection and Mitochondrial Disease

Pei She (Rachel) Loh, Volker Patzel

Department of Microbiology and Immunology, National University of Singapore, Singapore, Singapore

Cell type-specific gene delivery which restricts gene transfer to therapy-relevant cells, hence reducing unwanted side effects caused by the ectopic expression of transgenes, remains one of the biggest challenges. To mitigate potential off-target effects, we developed a programmable cell type-specific gene therapy using an RNA *trans*-splicing-based approach for gene replacement therapy or suicide gene therapy that can selectively express therapeutic proteins or suicide signals based on the cell's endogenous pre-mRNA expression profile. Using the liver

as a medical target organ, we developed a hepatocellular carcinoma (HCC)-specific *trans*-splicing based Herpes simplex virus thymidine kinase (HSVtk)/ganciclovir (GCV) suicide gene therapy approach. We designed suicide RNAs that can target multiple HCC-related pre-mRNA biomarkers thereby increasing the overall concentration of targetable pre-mRNA. Our latest generation of such multi-targeting constructs exhibited the highest cell death activity even at a GCV concentration of only 0.3 μM. For cell-type specific delivery, the conjugation of dumbbell vectors with $GalNAc_3$ residues enabled targeted delivery into hepatoblastoma-derived human tissue culture cells. To deliver nucleic acids into the mitochondria of human cells, we studied the long non-coding β2.7 RNA of the human cytomegalovirus which was previously reported to colocalise with mitochondrial complex I. Using thermodynamic profiling, we identified four thermodynamically conserved structural subdomains within the β2.7 RNA that are responsible for its mitochondrial targeting activity. A vector comprising eight mitochondrial targeting domains exhibited a three times higher mitochondrial targeting activity as compared with the parental β2.7 RNA. The amalgamation of mitochondrial targeting RNA and *trans*-splicing allows cell type-specific transcription of mRNA which can be delivered into mitochondria for mitochondrial gene therapy. *Trans*-splicing based gene therapy represent a technology that is highly translational offering promising perspectives towards suicide gene therapy of cancer or incurable infections with integrating viruses and may enable cell type-specific mitochondrial gene therapy.

929 Optimizing AAV Transduction with Modulators of DNA Repair Pathways

Aradhana Kasimsetty[1], Young Hwang[1], John K. Everett[1], Alexander G. McFarland[1], Aoife M. Roche[1], Maria C. Seleme[2], Allysen C. Henriksen[2], Denise E. Sabatino[2,3], Frederic D. Bushman[1]

[1]Department of Microbiology, Perelman School of Medicine, The University of Pennsylvania, Philadelphia, PA,[2]The Raymond G. Perelman Center for Cellular and Molecular Therapeutics, The Children's Hospital of Philadelphia, Philadelphia, PA,[3]Department of Pediatrics, Perelman School of Medicine, The University of Pennsylvania, Philadelphia, PA

Introduction: Modulating DNA repair pathways can be associated with enhanced adeno-associated virus (AAV) gene expression, leading to an interest in using these modulators to enhance AAV delivery *in vivo*. The role of many of these modulators in AAV integration has not been studied in detail, raising concerns about potential genotoxicities. AAV's safety derives partly from its primary persistence as an extrachromosomal episome, but the integration of AAV DNA has the potential to result in genotoxicity. Preclinical studies have identified cases of hepatocellular carcinoma and clonal expansion linked to integrated AAV in animal models. AAV integration has been associated with double-stranded DNA breaks and is mediated by DNA repair pathways, such as non-homologous end joining (NHEJ). As rearrangements and truncations have been identified in integrated AAV genomes, we have been developing methods to assess the effects of DNA repair modulators on AAV integration and rearrangement. **Methods:** We have developed a system for modulating DNA repair pathways during AAV transduction of primary cells and transformed cell lines. After diluting out episomal forms, we measured transgene expression and vector copy numbers (VCNs) to estimate integration frequency. Then, the structure and frequency of AAV integrands in these cells were characterized with ligation-mediated PCR and Illumina paired-end sequencing methods followed by analysis with the custom software pipeline AAVengeR. **Results:** Preliminary results have identified modulators of DNA repair pathways that only modulate early transduction as well as modulators that affect both early transduction and integration. Initial results suggest that increases in transduction in the presence of some modulators may not be entirely due to increased second-strand DNA synthesis and begin to indicate additional mechanisms. **Conclusions**: By developing a better understanding of these associations, we hope to optimize AAV transduction while reducing integration-mediated genotoxicities

930 Characterization of the Muscular and Cardiac Diseases of the DMSXL Mouse Model, a Transgenic Mouse Model for Myotonic Dystrophy Type 1

Caroline Le Guiner[1], Thibaut Larcher[2], Aude Lafoux[3], Gilles Toumaniantz[4], Stacy Webb[5], Geneviève Gourdon[6], Philippe Moullier[5], Joerg Votteler[5], Scott Hammond[5], Anna Tretiakova[5]

[1]TaRGeT Lab, Nantes Université, CHU de Nantes, INSERM, Nantes, France,[2]APEX, INRAE, ONIRIS, PanTher, Nantes, France,[3]Therassay, Capacités SAS, Nantes, France,[4]Institut du Thorax, Nantes Université, CHU de Nantes, CNRS, Nantes, France,[5]Asklepios BioPharmaceutical, Inc. (AskBio), Durham, NC,[6]Centre de Recherche en Myologie, Sorbonne Université, INSERM, Paris, France

Myotonic Dystrophy type 1 (DM1) is an autosomal dominant, progressive, and multi-systemic genetic disorder affecting at least 900,000 individuals worldwide. It is primarily characterized by myotonia, muscular weakness, and muscle atrophy. Other clinical manifestations include cardiac conduction defects, cardio-respiratory problems, cataracts, endocrine dysfunction and frequent neurological manifestations. The disease is caused by unnaturally expanded repeats of CTG trinucleotide in the 3'-untranslated region of the *DMPK* (dystrophia myotonica protein kinase) gene. In DM1 patients, the number of CTG repeats within the mutant *DMPK* allele ranges from 50 to 5000. The number of repeats roughly correlates with disease onset, severity and life expectancy (more repeats correlated with earlier onset, more severe symptoms and shorter lifespan). CTG-containing mutant DMPK transcripts are toxic. They aggregate as nuclear *foci* and impact the expression and function of RNA-binding proteins (such as MBNL1 and CELF1), resulting in spliceopathy of downstream effector genes, which accounts for much of the disease phenotype. Several therapeutic approaches either pharmacological or gene-therapy based, are under investigation to address this unmet medical need. One current limitation for the efficient evaluation and development of therapeutic products is the lack of DM1 animal models that ideally recapitulate the symptoms and the complex pathophysiology of this disease. Among available animal models, one of the most relevant remains the DMSXL mouse model, which carries a 45-kb human genomic fragment including the *DMPK* gene with more than 1200 CTG repeats. The human *DMPK* transgene is under the control of its own promoter and has been shown to have an almost ubiquitous expression. Initial characterization studies demonstrated

that homozygous DMSXL mice display several manifestations of the human DM1 pathology, including growth retardation, muscle defects, cognitive impairments, nuclear *foci,* and splicing abnormalities. After establishing a colony in our own facility, our goal was to define in our hands the most relevant and sensitive readouts that characterize this animal model, especially for its muscular and cardiac diseases, in both genders. Different groups of male and female DMSXL mice and littermate wild-type controls were followed and evaluated at 1 and 4 months of age. Weights, clinical status and blood biomarker concentrations were analyzed. Muscle strength and endurance were measured using grip force test and treadmill test, respectively. Cardiac function was evaluated using 2D-echocardiography analysis, and conventional measurement of electrocardiography parameters before and after challenge with flecainide, a pharmacological stressor of conduction disorders. Finally, after sacrifice, muscle and cardiac tissues were analyzed for levels of expression of human and murine DMPK transcripts, expression of MBNL1 and CELF1, splicing abnormalities, CTG-containing nuclear *foci*, muscle fiber type, muscle fiber size, and global histopathological lesions. Importantly, to avoid bias in the analysis, experiments were done in a blinded fashion. The data obtained in the frame of this study will be presented. They will be of importance to design further preclinical studies for the evaluation of the efficacy and safety of different therapeutic products designed to treat DM1 at the muscular and cardiac levels.

932 RGX-111 Gene Therapy for the Treatment of Severe Mucopolysaccharidosis Type I (MPS I): Interim Analysis of Data from the First in Human Study

Laura Pisani[1], Raymond Wang[2], Can Ficicioglu[3], Roberto Giugliani[4], Jenna Burke[5], Michele Fiscella[6], Lin Yang[5], Michelle Gilmor[1], Yoonjin Cho[1], Dawn Phillips[1], Paulo Falabella[6]

[1]REGENXBIO Inc. - Rockville, MD, Rockville, MD,[2]CHOC Children's Hospital, Orange, CA,[3]Children's Hospital of Philadelphia, Philadelphia, PA,[4]Department of Genetics, UFRGS, Medical Genetic Service, HCPA, Porto Alegre, Brazil,[5]Regenxbio, Rockville, MD,[6]REGENXBIO Inc., Rockville, MD

MPS I is a rare, autosomal recessive disease caused by deficiency of alpha-L-iduronidase (IDUA), an enzyme required for the breakdown of lysosomal glycosaminoglycans (GAGs). These GAGs accumulate in tissues of MPS I patients, resulting in characteristic storage lesions and diverse clinical signs and symptoms. In Hurler and Hurler-Scheie MPS I phenotypes, central nervous system (CNS) GAG accumulation leads to hydrocephalus, spinal cord compression, and cognitive impairment. Current disease-modifying therapies for MPS I include hematopoietic stem cell transplant (HSCT) and intravenous enzyme replacement therapy (ERT) with recombinant human IDUA. However, ERT does not treat the CNS manifestations of MPS I, and HSCT can be associated with clinically significant morbidity and mortality. RGX-111, a recombinant adeno-associated virus serotype 9 capsid containing a human IDUA expression cassette (AAV9.CB7.hIDUA), administered to the central nervous system (CNS) may provide a permanent CNS source of secreted IDUA, potentially preventing the progression of cognitive deficits that otherwise occur in MPS I patients. In this phase 1/2, first-in-human, multicenter, open-label, dose escalation trial (NCT03580083), participants with documented evidence of CNS involvement or severe MPS I $\geq$ 4 months of age receive one image-guided RGX-111 injection to the CNS with 104 week follow-up for safety, tolerability, and efficacy. Participants are encouraged to enroll into a long-term, follow-up study for a total of 5 years. Assessments include measurements of cerebrospinal fluid, plasma, and urine biomarkers; cognitive, language, and motor neurodevelopmental scales; and imaging. Subjects have been enrolled at Dose 1 and Dose 2 ($1.0x10^{10}$ and $5.0x10^{10}$ genome copies/gram brain mass, respectively). Interim results of this trial will be presented. Additionally, follow-up will be reported for a severe MPS I child treated at age 21 months utilizing a single-patient, investigator-initiated Investigational New Drug application.

933 Hybrid Dual AAV Vector System with Novel Synthetic Splice Enhancer Elements for Increased Efficiency of Splicing and Gene Expression

Chitra Gopinath[1], Joy Elvin Dhinakar[1], Trailokyanath Panigrahi[1], Barathi Veluchamy A[2], Arkasubhra Ghosh[1]

[1]GROW Laboratory, Narayana Nethralaya Foundation, Bangalore, India,[2]Translational Pre-Clinical Model Platform, Singapore Eye Research Institute, Singapore, Singapore

The cargo DNA packaging capacity limitation of recombinant AAV vectors of 4.7kb are overcome by various dual/split gene strategies. Current dual vector strategies have demonstrated superiority in final transgene expression level from the delivery of large therapeutic genes. Dual hybrid vector platforms utilise both ITR mediated and an intronic overlapping element for recombination between the two half-vector genomes for transgene reconstitution. The splice donor and acceptor signals flanking the overlapping sequence thus affect the intron removal, highlighting a critical hurdle for final protein expression. Here, we have developed a synthetic, small sequence containing splice enhancer elements arranged in tandem with high recombination potential to test the hypothesis that dual vector efficiency may be enhanced by efficient splicing. This novel 90 bp synthetic splice enhancer intron (SEIa) was cloned into *LacZ* and *ABCA4* cassettes driven by CMV promoter. SEIa was compared to the previously reported 297 bp AP sequence (OAP). Single vector *LacZ* control and hybrid dual vector genomes containing either SEIa or OAP were packaged in AAV9 capsids for *in vitro* and *in vivo* analysis. Subretinal and intramuscular *LacZ* dual vector injections were administered into 4-week-old C57BL/6 mice at each vector dosage of 2.5x10^9vg/eye and 1x10^10vg/TA muscle. *LacZ* expression was analysed by histochemical staining, 6-8 weeks post injection. Percentage of *LacZ* positive TA muscle fibres from the SEIa vectors (82.9% ±3.8) were significantly (p=0.0004) higher compared to the OAP vectors (48.0% ±6.6). In the retina, *LacZ* expression measured by the diffusion area percentage were significantly (p=0.03) higher in the SEIa group (45.8 ±0.8) compared to the OAP group (40.5 ±1.4). Molecular analysis of splicing efficiency using qPCR and PCR for proportions of spliced and unspliced mRNA demonstrated lesser proportions of unspliced mRNA in the SEIa dual vectors compared to OAP. We further applied this strategy to the 6.8kb gene *ABCA4*, which is mutated in Stargardt's macular degeneration and tested it for *in vivo* functional recovery. Six-month-old *Abca4*$^{-/-}$

animals were injected sub-retinally with AAV9.*ABCA4* dual vectors, 5′ or 3' vector alone or sham. Retinal structural and functional changes of all groups were assessed weekly by fundus and FFA imaging, ERG analysis prior to sacrifice followed by histology 8 weeks post injections. AAV dual vectors (both SEIa and OAP) administered *Abca4*$^{-/-}$ eyes demonstrated significantly reduced lipofuscin deposits (~60-70%) and significantly recovered retinal function on ERG (n=6/group, $p<0.05$) compared to single vector (half gene) and sham controls 2 months post infection. While both OAP and SEIa dual vector retinae had higher levels of Rhodopsin and Opsin expression, the SEIa dual vector treated eyes showed highest levels of Rhodopsin expression compared to control *Abca4*$^{-/-}$ eyes. The synthetic 90 bp splicing enhancer sequence containing AAV dual vectors performed better than the currently existing dual vectors in both retina and muscle. The smaller sequence further increases the overall packaging capacity by an additional 400bp without compromising on recombination efficiency. We demonstrate that the higher transgene expression is partly explained by the enhanced splicing efficiency. Our results in Stargardt disease model validates the application of this new dual vector strategy for diverse diseases with causative, large genes.

934 Identification of Universal Parameters That Play a Critical Role in rAAV Production Using a Transient Two-Plasmid Packaging System in the Adherent HEK293T Cell Line

Filip De Vin, Irina Thiry, Kristel Vuerinckx, Jolien Van Dijck, Nathalie Van Den Berghe, Elien Costermans, Kirsten Welkenhuyzen, Sofie Molenberghs, Benjamien Moeyaert, Els Henckaerts

Laboratory of Viral Cell Biology & Therapeutics, Department of Cellular and Molecular Medicine, KU Leuven, Leuven, Belgium

Adeno-associated virus (AAV) is the vector of choice for gene therapy due to its relatively good safety profile and persistence. Consequently, the number of AAV clinical trials are expanding rapidly. To meet the increasing demand, challenges in manufacturing of recombinant AAV (rAAV) viral vectors such as low yields and low full:empty capsid ratios in unpurified material need to be tackled. In this work, we studied the effect of critical process parameters that determine the yield and quality of rAAV production. We started from a baseline rAAV production protocol based on the adherent human embryonic kidney (HEK)293T cell line in combination with a two-plasmid transient transfection system in which *rep* and *cap* genes and Ad helper genes are on the same plasmid. As this protocol routinely yields decent yields and full:empty ratios, we considered it a good starting point for identifying the process parameters that lead to superior rAAV production yields. We evaluated the effect of plasmid quantification, confluency at the time of transfection, total plasmid DNA (pDNA) amount, DNA:PEI ratio, and plasmid ratio on vg titer, VP titer and % full for AAV2, AAV5, and AAV9. In addition, we measured the intracellular average copy number of the different plasmids 16h after transfection in HEK293T cells to allow monitoring of the effect of aforementioned parameters, both on transfection efficiency as on AAV production. In an effort to obtain more reproducible transfection conditions, we found that determining pDNA concentrations using the Invitrogen Qubit HS assay was more reliable than using a Nanodrop spectrophotometer. Most likely, this is due to the tendency of traditional UV absorbance-based methods to overestimate sample concentrations due to the presence of contaminants. We found that there is an optimum in terms of amount of total pDNA and the DNA:PEI ratio at which maximum transfection efficiency is obtained, which correlated well with intracellular pDNA copy numbers and the % full particles. Moreover, an inverse relationship between total vg and % full particles was observed, meaning that parameters that increase total vg concomitantly decrease % full and vice versa. Independent of the serotype, the best results for rAAV production were obtained by decreasing the helper:production plasmid ratio, with a gradual decrease in total vg though concomitant increase in % full. In summary, we found that UV absorbance-based methods for pDNA quantification do not form a reliable basis for rAAV production process development, and that monitoring of intracellular pDNA copy numbers allow for better insight into the transfection and production process. Moreover, we observed an inverse relationship between total rAAV particle yield and percentage full. The driving force behind this relationship is yet unclear and the subject of follow-up research.

935 Omics Integration for Enhanced Peptide Discovery for Cancer Immunotherapy

Salvatore Russo[1], Manlio Fusciello[1], Sara Feola[1], Jacopo Chiaro[1], Gabriella Antignani[1], Michaela Josefine Feodoroff[1], Firas Hamdan[1], Riikka Mölsä[1], Mikaela Grönholm[1], Olli Dufva[1], Satu Mustjoki[1], Rui Mamede Branca[2], Janne Lehtiö[2], Giusy Del Giudice[3], Antonio Federico[3], Dario Greco[1,4], Vincenzo Cerullo[1,5]

[1]University of Helsinki, Helsinki, Finland,[2]Karolinska Institute, Stockholm, Sweden,[3]University of Tampere, Tampere, Finland,[4]Faculty of Medicine and Health Technology, Univeristy of Tampere, Tampere, Finland,[5]Department of Molecular Medicine and Medical Biotechnology and CEINGE, University Federico II, Naples, Italy

Cancer Immunotherapies have dramatically changed how cancer is treated nowadays. Advances in understanding anti-tumour immune response have provided novel strategies to precisely target malignant cells.In particular, the majority of anti-cancer vaccines and adoptive T-cell therapies rely on the accurate identification and validation of tumour-specific and tumour-associated antigens (TSAs and TAAs, respectively) displayed on the tumour surface through HLA-I molecules. Unfortunately, many antigens are poorly shared among patients and in addition, they show a significant degree of intra-tumoral heterogeneity. Furthermore, malignancy is associated with endogenous retroviruses (ERVs) reactivation upon genetic and epigenetic deregulation, a phenomenon observed in patients as well. Since ERVs and other classes of transposable elements (TEs) constitute over 45% of our genome while being unexpressed in normal cells, their reactivation could provide novel immunogenic HLA-I ligands, thus increasing the patient cohort'seligibility for therapeutic cancer vaccines.Hypomethylating agents (HMAs)(e.g. Azacytidine (AZA) and Decitabine (DAC)) are approved for the treatment of myelodysplastic syndrome (MS) and acute myeloid leukaemia (AML); the ability to further de-repress ERVs and activate anti-viral innate immunity in cancer cells has recently been speculated to be the actual mode of action of these drugs. Despite the promising results in preclinical studies, clinical knowledge regarding the HMA-induced set of ERV ligands

and their expression rate on the tumour surface is still limited. We here propose a deep Omic integration analysis approach for identification and selection to exploit HMAs' potential as a priming agent to unravel ERV targets for peptide-based immunotherapy.

936 Simple, Rapid and Robust Bioluminescent Cell-Based Assay for Detecting Neutralizing Antibodies Against AAV in Serum

Morten Seirup, Kirsten Wingate, Jeff Nelson, Kara B. Machleidt, Vanessa L. Ott, Trish Hoang, Marjeta Urh
Promega Corporation, Madison, WI

Adeno-associated viruses (AAV) are widely used vectors for gene therapy, capable of delivering transgenes as treatment for monogenic diseases. Individuals with pre-existing immunity to AAVs are less likely to benefit from AAV-based therapies due to both, a reduction in cellular AAV uptake and activation of a cytotoxic T-cell response to transduced cells, decreasing efficacy or changing the safety profile. A robust and reliable neutralizing antibody (NAb) assay is necessary to determine eligibility for treatment as well as to identify qualified individuals for clinical trials. Here we present a cell-based assay using NanoLuc® luciferase to detect NAbs in serum samples. This NanoLuc® AAV reporter system displays several advantages over existing assays such as: superior sensitivity, very low MOI required (100 - 3000 depending on serotypes), short 24h assay time, and detection using a standard luminometer. We tested 60 human serum samples for the presence of NAbs against a panel of AAV serotypes 1—10 and engineered variant AAV-DJ. We found that a large fraction of the population had pre-existing NAbs to at least one serotype, and of the pre-exposed individuals a majority displayed NAbs against multiple AAV serotypes. Interestingly, fewer samples were seropositive for AAV-DJ than for either parental serotype (AAV2, AAV8 or AAV9), highlighting the benefit of capsid engineering. Furthermore, a broad dynamic range of our assay enables categorizing the serum samples into 4 groups: negative, low, medium and high NAb tiers. Representative samples of each group were assayed for neutralizing titers (ND_{50}). The ND_{50} values of the samples showed agreement with their assigned groups. To demonstrate the robustness of our assay, we conducted a mouse study with 40 mice divided into 4 groups and administered AAV9 at varying doses. This study showed a strong correlation of NAb levels to the injected AAV viral loads. Taken together, our assay is rapid, highly sensitive and reliable; the NanoLuc® AAV reporter technology enables precise measurement of NAbs against AAVs in serum. Further validation of the assay is required for future use in a clinical setting.

937 New AAV Capsids with Increased Transduction Efficiencies of Human Airway Epithelia

Ashley L. Cooney[1], Christian Brommel[2], Patrick L. Sinn[1]
[1]University of Iowa, Iowa City, IA,[2]University of Iowa Hospitals and Clinics, Iowa City, IA

A major hurdle for cystic fibrosis (CF) gene therapy in the lung is delivery. Our goal is to achieve life-long correction from a single dose of aerosolized viral vector. As such, efficient delivery of a therapeutic gene or gene editing machinery to airway progenitor cells is critical. In this study, we use adeno-associated virus (AAV)-based vectors as vehicles for stable delivery of genes of interest to airway cells. Basal cells comprise an important progenitor population in the conducting airways and are responsible for replenishing multiple surface epithelial cell types. Thus, this cell population is an important gene therapy target. Here, we modify two capsids with demonstrated tropism for the conducting airways, AAV2.5T and AAV6.2, to further improve basal cell transduction. AAV2.5T and AAV6.2 are two capsid types that were generated by directed evolution to achieve improved airway tropism. AAV2.5T is a combination of AAV2 and 5 with a point mutation A581T. AAV6.2 is the AAV6 capsid with a mutated F129L residue. Both A581 and F129 are present in AAV6.2 and AAV2.5T. We first asked if incorporating reciprocal residues would increase airway tropism in primary surface epithelia and basal cells, termed AAV2.5T_F129L and AAV6.2_A581T. We next asked if modifying surface tyrosine residues would enhance transduction efficiencies as has been reported with the 6.2FF capsid (Y445F, Y731F). To this end, we generated a AAV2.5T_FF capsid by modifying Y437F and Y720F residues. Lastly, we generated combinatorial mutations, termed AAV2.5T_FFL and AAV6.2FFT. We compared transduction efficiencies on the apical surface of well differentiated primary airway epithelia as well as primary basal cells. GFP was quantified by flow cytometry 3 weeks post-transduction. Ratios of cell types were confirmed by flow cytometry. We observed increased transduction efficiencies using the AAV2.5T_F129L and AAV2.5T_FFL capsids compared to AAV2.5T alone. Additionally, we observed increased GFP expression with the AAV6.2FF capsid relative to AAV6.2. As expected, ratios of cell populations transduced remain unchanged with capsid modification. Apical transduction leads to mostly ciliated and secretory cells transduced, but basal cells are also transduced. Overall, AAV2.5T transduces surface epithelia with higher efficiencies than AAV6.2, however AAV6.2 better transduces airway basal cells. To assess AAV-mediated delivery in a CF model, we used a split intein system to deliver adenine base editors (ABEs) fused to a CRISPR/Cas9 nickase to primary CF cells. Using this approach, we observed efficient base editing at the R553X locus. Correcting both surface and airway progenitor cells are important for achieving life-long therapeutic benefits from cystic fibrosis gene therapy.

938 Increased Striatum Transduction with an Engineered AAV Capsid and Selective Transduction of Striatal Cholinergic Neurons Using a Truncated Human Choline Acetyltransferase Promoter

Miguel C. Santoscoy[1,2,3], Paula Espinoza[1,2,3], Demitri De La Cruz[1,2,3], Mohammed Mahamdeh[1,4], Jacqueline R. Starr[1,5], Nikita Patel[1,2,3], Casey A. Maguire[1,2,3]
[1]Harvard Medical School, Boston, MA,[2]Department of Neurology, Massachusetts General Hospital, Boston, MA,[3]Molecular Neurogenetics Unit, Massachusetts General Hospital, Charlestown, MA,[4]Cardiovascular Research Center, Massachusetts General Hospital, Charlestown, MA,[5]Channing Division of Network Medicine, Brigham and Women's Hospital, Boston, MA

Introduction. Adeno-associated virus (AAV) vectors are currently the most efficient option for intracranial gene therapies to treat

neurodegenerative disease. The striatum is the largest structure of the basal ganglia, and it plays a major role for movement and cognition. Alterations in the physiology of striatal cholinergic neurons have been found in human brains with motor diseases such as Parkinson's Disease. Increased efficacy and safety will depend upon robust and specific expression of therapeutic genes into specific cell-types within the human brain, including cholinergic neurons. In this study we set out with two objectives: (1) to identify capsids with broader transduction of the striatum upon intracranial injection in mice and (2) to test a truncated human choline acetyltransferase (ChAT) promoter which would allow efficient and selective transduction of cholinergic neurons. **Materials and Methods.** We first compared AAV9 and an engineered capsid, AAV-S, to mediate widespread reporter gene expression driven by the strong, broadly active CAG promoter (AAV-CAG-tdTomato) throughout the striatum in wild-type C57BL/6J mice. We also constructed an AAV expression plasmid containing a truncated human choline acetyltransferase (ChAT) promoter driving tdTomato expression (AAV-hChATp-tdTomato) to allow efficient and selective transduction of cholinergic neurons in mice. We used transgenic ChAT(BAC) eGFP mice with fluorescently labeled cholinergic neurons to allow accurate identification of transduced ChAT positive cells. We compared the ChAT promoter head-to-head with the CAG promoter to drive the expression of tdTomato after packaging into the tested AAV capsids. Mice were stereotactically injected with AAV-vectors into the striatum and 14-16 days post-injection, brain was collected and coronally sectioned. Confocal microscopy in Z-stack mode was utilized to quantify percentages of transduction efficiency and specificity. **Results.** We observed that AAV-S-CAG-tdTomato transduced a statistically significantly greater area, up to 3.2-fold, of the injected hemisphere primarily in the rostral direction compared to AAV9-CAG-tdTomato in C57BL/6 mice. The majority of transduced neurons appeared to be medium spiny neurons. For transduction of cholinergic neurons, we observed that AAV-hChATp-tdTomato mediated 7-fold higher selectivity of transduction of cholinergic neurons compared to AAV-CAG-tdTomato. Furthermore, the AAV9-hChAT-tdTomato vector increased the specificity and efficiency of transduction by 7-fold and 3-fold, respectively, compared to AAV9-CAG-tdTomato. **Discussion and conclusions.** The ability of AAV-S capsid to transduce a larger area of the murine striatum compared to AAV9, motivates further testing of AAV-S in large animals which may allow less invasive surgeries if less intracranial injections are required to transduce the striatum. The increased AAV transduction specificity and efficiency towards striatal cholinergic neurons *in-vivo* driven by the truncated ChAT demonstrates the utility of this AAV-vector as a tool for genetic modification of these cells and potential development of gene therapies targeted at cholinergic neurons.

939 Simultaneous Engagement of NK Cell Siglec-7 and FSHR Demonstrates a Promising Therapeutic Strategy Against Ovarian Cancer

Devivasha Bordoloi[1], Abhijeet J. Kulkarni[1], Opeyemi S. Adeniji[1], M. Betina Pampena[2], Pratik Bhojnagarwala[1], Shushu Zhao[1], Rugang Zhang[1], Michael R. Betts[2], Mohamed Abdel-Mohsen[1], David B. Weiner[1]

[1]The Wistar Institute, Philadelphia, PA,[2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Targeted cancer immunotherapies have been a subject of significant clinical interest. Most of the recent developments have focused on unleashing tumor antigen-specific T-cell responses. Despite considerable success, their clinical benefit has been restricted to a subset of patients and selected tumor types, suggesting the need for additional complementary approaches. In this regard, NK and T cell strategies have unique cytokine profiles providing differential opportunities in specific therapeutic situations. Recently, NK cell engagers (NKCEs) have gained attention due to their anti-tumor activity and unique inflammatory profile. However, no NKCE has been clinically approved to date. NK cells, similar to T cells have described negative regulatory markers. One such potential marker is Siglec-7, which binds to sialoglycans on cancer cells. Attempts have been made to denude target cells of sialic acid moieties to prevent Siglec 7 from negatively regulating NK cell activation against tumors. We developed human Siglec-7 mAbs and show they can block negative signals driven by hypersyalylation of tumor cells. We hypothesized that Siglec-7 could be used as a NK cell engagement target as it would provide dual binding and activation. A unique clone DB7.2 exhibited high specificity for Siglec-7. We used this Fab and developed a NKCE by fusing with the Fab of a potent FSHR binding mAb (D2AP11) and studied this new NKCE for activity against diverse ovarian cancers (OCs). OC is highly heterogenous with poor survival post diagnosis using current modalities including traditional T cell-CPI blockade. We confirmed the NKCE would simultaneously bind to Siglec-7 and FSHR bringing NK cells into direct contact with FSHR+ OC cells. The NKCE was specific and potent in tumor cell killing, as evaluated by xCelligence RTCA against a panel of divergent OC lines carrying a wide array of important mutations (BRCA1&2, AKT, TP53, PIK3CA, BRAF). These tumors are patient derived and show resistance against different cancer drug targets (HSP90, HDAC, MTORC, DNA alkylating agents, EGFR, PARP, PI3K). The NKCE induced concentration dependent cell killing in OVISE-FSHR and OVCAR3 cells with EC50s of 142.87 pM and 236.6 pM, showing high potency of this new biologic. FSHR negative cells were not targeted by this NKCE, demonstrating that FSHR expression on target is required for NK mediated killing. In addition, the NKCE binding to tumor cells stimulated NK to produce sFas and granzyme A. It also attenuated tumor burden and significantly improved survival of mice in two different OC tumor challenge models. Additionally, the combination of FSHR targeted NK and T cell engagers resulted in synergistic killing of Kuramochi cells in presence of human PBMCs. This is the first demonstration of the potency of human anti-Siglec-7 for activation of NK cells to target pathogenic cells, and the first example of the development and study of bispecific Siglec-7 NK engagers. These results support Siglec7 NKCE targeting approaches as new tools for OC and potentially other cancers.

940 Scaling up Strategy for Oncolytic Herpes Simplex Virus Type-1 Vector Manufacturing

Lingjing Tang, Jun Wang, Shiyi Mei, Zhengrui Xiong, Zihao Fang, Han Gao, Weiran Shen, Houliang Wei
OBiO Technology (Shanghai) Corp., Ltd., Shanghai, China

Genetically modified recombinant herpes simplex virus type-1 (HSV-1) is widely used as an oncolytic virotherapy to stimulate anti-tumor immune responses by replicating in cancer cells. Conventional production of HSV-1 vectors uses adherent-based methods involving cell factories or roller bottles, which is time, people, space consuming and difficult for scaling up. In previous study, we reported the development of a high-titer, high quality production process of HSV-1 vectors utilizing Univercells Technologies' scale-X™ hydro system. In this study, we demonstrated the scalability of the previously developed HSV-1 production process on scale-X™ carbo system with consistent quality profiles. The process on adherent Vero cells culturing in fixed bed bioreactors was scaled-up to 30 sqm total growth surface area, which is equivalent to 350 roller bottles or twelve 40-layers large cell factories. The peak cell density and peak virus titer were measured and critical quality attributes including residual host cell DNA and host cell protein were determined. The results indicated that the virus yield from a 30 sqm fixed bed culture is comparable to traditional roller bottle, which significantly reducing the requirements on manpower, material, and space. The yield and quality of vector production showed consistency when scaling up from hydro bioreactor to scale-X™ carbo system, and the consistency is likely to be there by further scaling up to 600 sqm scale-X™ system.

941 DMSO Promotes AAV Production in Scalable Suspended HEK293 Cells

Chang Xie[1], Wayne Mak[1], Christopher Coble[1], Dwaipayan Sen[2]
[1]Vector Biosciences, Astellas Gene Therapies, South San Francisco, CA,[2]Astellas Gene Therapies, San Francisco, CA

AAV production for gene therapies faces the challenge of high-cost manufacturing and improving the yields can potentially lower the cost. We screened for molecules that could increase AAV production in scalable HEK293 suspension cultures. Among these molecules, DMSO was identified to robustly increase AAV production regardless of transfection reagents or AAV serotypes were utilized. DMSO has been reported to boost transfection efficiency in multiple adherent cell lines by high-concentration DMSO shock. This type of DMSO shock is not applicable to suspension cultures due to the difficulty of completing the process within a minute, and that changing the medium would require centrifugation and re-suspension, which would distress the cells. We treated the cells with different concentrations of DMSO for 72 hours and measured their viability. We found that HEK293 suspension cells can well-tolerate 2% DMSO. Therefore, various DMSO concentrations that were ≤2% were used to treat the cells during AAV packaging. There was a dose-dependent increase in AAV vector genome (vg) titer. This increase was stably observed with different transfection reagents, different AAV serotypes, and different scales. An additional benefit is that DMSO does not affect downstream purification and can be easily removed from the product. In addition to increasing in vg titer, there was a robust increase of full capsid ratio, which is an important parameter for AAV purification. In summary, DMSO can boost AAV production and potentially reduce manufacturing cost.

942 A Low-Cost, Highly Stable, and Scalable Assay to Interrogate Effectors of rAAV Transduction

Brian Benyamini, Anna C. Maurer
Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

Recombinant adeno-associated viral (rAAV) vectors are increasingly popular platforms for *in-vivo* gene therapy. Novel rAAV capsids and transgene components that increase transduction efficiency and cell type specificity are highly active areas of research that can benefit from effective high-throughput transduction assays to screen large arrays of vectors. Pharmacological agents can also increase transgene expression but have been less explored due to the lack of a robust platform for small molecule screens. Here, we describe a method to evaluate rAAV transduction using a homemade reporter assay we call *LacZ*-Activated Fluorescence Assay (LAFA). Briefly, cells are transduced with *lacZ*-packaged rAAV, lysed, and mixed with the substrate 4-methylumbelliferyl-ß-D-galactopyranoside (MUG), a fluorogenic galactose analog. Upon cleavage by -galactosidase, 4-methylumbelliferone (MU) is released and fluoresces blue. The cost-effectiveness, ease of use, and practicality of LAFA pose several advantages over ubiquitously popular luciferase-based reporter assays. Our homemade assay is roughly 50-times less expensive than commercial luciferase or fluorescence kits, requires minimal reagent preparation, and can be scaled up to a 384-well plate format. Because the fluorescent readout is stable for hours compared to minutes in luciferase assays, LAFA does not require the use of plate readers with reagent injectors and is thus better suited to scale-up and use in liquid handling robotic platforms. Additionally, MUG may be replaced by fluorogenic galactose analogs with green, red, or far-red spectra, owing to the versatility of the approach and providing researchers the ability to customize the assay based on their unique needs. Using LAFA, we assayed transduction by a trans-splicing dual vector, an approach previously engineered by others that can double the transgene size deliverable by rAAV. The 5' half of *lacZ* is flanked by a promoter and splice donor, packaged in an AAV2 capsid, and co-delivered with a separate AAV2 vector packaging the 3' half of *lacZ* flanked by a splice acceptor and polyA. As expected, transduction of cultured cells by the dual vector was 10-fold lower than by an unsplit, single *lacZ* packaged vector. We then used LAFA as a readout to test the effects on transduction of small molecular inhibitors targeting DNA damage repair (DDR) factors hypothesized to be involved in vector genome processing. Inhibiting the non-homologous end joining (NHEJ) protein DNA-PK results in a 10-fold reduction in dual vector transduction. Conversely, by inhibiting the homology-directed repair (HDR) protein Rad51, we observe a 10-fold increase in dual vector transduction, with RFUs comparable to unsplit *lacZ* single vectors. All observations were dose-dependent with respect to both the small molecule and vector. These results suggest that NHEJ supports dual vector transduction, while HDR impedes it. The versatility and accessibility of LAFA enables

studies that will advance our knowledge of rAAV biology and progress the development of novel vector designs and transduction-enhancing drug discovery via high-throughput screens.

943 Assessing the Effect of Dosage and Injection Route on AAV Gene Therapy in the Treatment of Feline GM2 Gangliosidosis

Courtney J. Garrett[1], Anne S. Maguire[1,2], Amanda L. Gross[1], Heather L. Gray-Edwards[3], Miguel Sena-Esteves[4], Douglas R. Martin[1,2]

[1]Scott-Ritchey Research Center, Auburn University, Auburn, AL,[2]Department of Anatomy, Physiology, & Pharmacology, Auburn University College of Veterinary Medicine, Auburn, AL,[3]UMass Chan Medical School, Worcester, MA,[4]Department of Neurology, UMass Chan Medical School, Worcester, MA

The GM2 gangliosidoses (GM2) are a class of fatal neurodegenerative disorders resulting from a mutation in the gene encoding β-N-acetylhexosaminidase (Hex). The naturally occurring feline model of GM2 is an effective animal model for characterizing disease progression and evaluating treatment efficacy. Adeno-associated viral (AAV) gene therapy for GM2 aims to restore Hex and minimize disease progression. Injection route is an important consideration in AAV therapy because the vector must reach areas of the body most relevant to the disease pathology. Moreover, AAV dosage must be high enough to generate a therapeutic effect without causing adverse effects. Intracranial injection of AAV into the thalamus and deep cerebellar nuclei is effective in increasing in the lifespan of GM2 cats, but the procedure is invasive and requires a craniotomy for delivery to the brain parenchyma. Injection of AAV into the cerebrospinal fluid via the cisterna magna (CM) is less invasive and may improve biodistribution to certain parts of the central nervous system. Intravenous injection is an even less invasive injection route and could be especially effective in treating peripheral organs. Furthermore, delivering vector via both CM and IV could yield the positive effects of both injection routes at the same time. This study compares the effects of AAV dosage and injection route on survival and disease progression in GM2 cats. Each cohort received a low dose (LD) of 5×10^{13} vector genomes/kg body weight (vg/kg) or a high dose (HD) of 2×10^{14} vg/kg, via CM, IV, or combined (CM+IV) routes. For the CM+IV injections, half of the total dose was administered via each injection route. Cats were treated at 1.15 ± 0.2 months of age. Animals in each cohort were observed either for 16 weeks post-treatment or until they reached humane endpoint. 7T MRI was used to assess neurodegeneration across cohorts. Magnetic resonance spectroscopy (MRS) was used to quantify several metabolites that are biomarkers for brain health. MRI showed delayed neurodegeneration in all cohorts, to some degree. When compared to normal cats at 4 months, the typical GM2 humane endpoint, untreated GM2 cats have isointense (equal intensity) gray and white matter. All treatment cohorts showed preservation of white matter at approximately 4 months. However, neurodegeneration and atrophy had progressed substantially in all treatment cohorts once the humane endpoint was reached (see survival below). At 4 months, MRI and MRS data for the treated cohorts correlated with delayed clinical symptoms, such as tremors and inability to stand. Ultimately, untreated GM2 cats survived 4.4±0.6 months (n=9), CM LD cats (n=4) survived 9.4±4.2 months, CM+IV LD cats (n=3) survived 14.1±4.4 months, CM+IV HD cats (n=3) currently have survived 13.1±3.3 months (study ongoing), IV LD cats (n=4) survived 8.3±1.2 months, and IV HD cats (n=4) survived 12.4±2.8 months. This study indicates that all dosages and treatment routes significantly increase the lifespan of GM2 cats and delay neurological disease progression when compared to untreated cats. This study indicates that all dosages and treatment routes significantly increase the lifespan of GM2 cats and delay neurological disease progression when compared to untreated cats.

944 Effect of an Anti-VSV-GP Antibody on Viral Pharmacokinectics and Biodistribution

Ashlee Bell-Cohn, Saeed Akhand, Joyce Swenson, Richard Dambra, Kaitlynn Graca, Alison J. Johnson, Joseph Ashour, Adam Vigil, Christine Grimaldi

Boehringer Ingelheim, Ridgefield, CT

Introduction: VSV-GP is a vesicular stomatitis virus (VSV) which has been pseudotyped with the glycoprotein (GP) from lymphocytic choriomeningitis virus (LCMV). VSV-GP is a novel oncolytic virus with potential therapeutic application. Regarding oncolytic virus based therapies, anti-viral antibodies may impact pharmacokinetics (PK) and biodistribution (BD) of these drugs. Anti-viral antibodies can also impact the safety and efficacy of oncolytic viruses. Therefore, it needs to be determined if these antibodies will be generated and if so what is the potential impact. The objective of these studies was to investigate the development of anti-viral antibodies to VSV-GP in mice and the effect of said antibodies on VSV-GP PK and BD. **Methods:** Female BALB/c mice were intravenously administered multiple doses of 10^8 TCID50 VSV-GP over a 2 week period. After the mice were rested for 2 weeks, they were sacrificed. Their serum was collected and analyzed via an MSD based indirect ELISA utilizing VSV N protein as coating antigen. In a separate study, an anti-VSV N IgG2a mouse monoclonal antibody (Clone 10G4, Kerafast, Cat # EB0009) was pre-incubated with VSV-GP and then administered in female BALB/c mice. Mice treated with VSV-GP alone were used as a control. After 1, 24, and 72 hrs, the mice were sacrificed and their blood, spleen, and liver tissue analyzed via RT-qPCR to assess viral titers. **Results:** All mice treated with VSV-GP developed anti-viral antibodies. Specifically, an antibody response against the nucleoprotein was detected. Coadministration of anti-VSV N antibody with VSV-GP in mice, produced similar viral genome copies as virus only treated mice in both spleen and liver tissue. However, in anti-N antibody treated mice, there was a distinct and log fold reduction in viral genome copies detected in the blood at 24hrs post infection compared to virus only treated mice. **Conclusions:** VSV-GP administration leads to anti-viral antibody development to VSV N protein. While all mice did develop a detectable antibody response to the N protein, the signal was low in this assay developed to evaluate anti-VSV-GP antibody responses. Anti-N antibody had no effect on biodistribution of VSV-GP in spleen and liver tissue. VSV-GP blood PK was affected by anti-VSV N antibody treatment in mice. Since there was no difference in genome copies in the blood at 1hr post infection, anti-N antibody was not disrupting viral egress from the blood. We postulate that administration of anti-N antibody leads to increased clearance of viral genomes that are associated with N protein, which has been released from infected cells.

945 Development of a Novel Non-Viral Gene Therapy Platform

Khal Hajj[1], Johannes Schwerk[2], Dongyang Zhang[2], Joseph Lucas[2], Brian Truong[2], Sang J. Espinoza[2], Pavan Battiprolu[2], Brent Warner[2], Mike Bennett[2], Blair Madison[2], Joshua Rychak[2]

[1]In Vivo Gene Therapy, Poseida Therapeutics, San Diego, CA,[2]Poseida Therapeutics, San Diego, CA

Gene therapy is a promising approach for treatment of severe bleeding disorders. AAV-based gene therapies have shown some success in this regard, though age restrictions, pre-existing capsid immunity, limited durability, and an inability to re-dose represent challenges to this platform. The super piggyBac® DNA insertion system is a transposon-based gene therapy platform that enables stable integration of the therapeutic transgene into the genome, thereby offering the potential for durable and lifelong activity. This platform requires two components: the super piggyBac transposase (SPB) and a piggyBac transposon comprising the therapeutic transgene expression cassette. The transposase functions by excising DNA cargo and inserting it into the genome, and can be efficiently delivered as mRNA. One key advantage is the super piggyBac platform accommodates large cargo; this is especially advantageous for diseases such as hemophilia A in which the transgene (hFVIII) is especially large. We hypothesized that combining the super piggyBac DNA insertion system with a non-viral delivery system could enable us to deploy this platform unconstrained by the cargo capacity limitations of AAV-based delivery systems, and potentially enable repeat dosing. The lipid nanoparticle (LNP) is a mature non-viral delivery platform that has been clinically successful for liver-specific delivery of siRNA and mRNA. The implementation of the LNP platform to deliver DNA, however, has been challenging. Successful implementation of our super piggyBac system requires: 1) the development of LNPs capable of effectively and safely delivering the transposase mRNA and donor DNA template to the same target cells, 2) optimization of the transposon DNA format and sequence, and 3) optimization of the SPB mRNA to maximize transposase expression to give optimal excision and insertion of our gene of interest. Using LNPs optimized using Design of Experiments (DOE), we explored (1) dual formulation, in which the transposon DNA and transposase mRNA are encapsulated in separate LNPs, and (2) co-formulation, in which the DNA and mRNA are encapsulated together within the same LNP. We observed substantial hFVIII expression (>100% of normal) in juvenile wild-type mice following a single intravenous dose. Optimization of the transposon DNA: transposase mRNA ratio resulted in a further 8-fold increase in FVIII expression for both formulation strategies. Delivery of the hFVIII DNA alone or in concert with a control transposase (unable to perform genomic integration) resulted in significantly (>10X) lower hFVIII expression than using functional SPB. Vector copy numbers remained low, with an insertion profile consistent with previous studies. Production of hFVIII in the expected therapeutic range (10-50%) was also confirmed in a mouse model of severe hemophilia A. Contrary to conventional AAV-based gene therapies, this fully non-viral approach also supports repeat dosing. Repeated administration of the transposon/transposase nanoparticle system over 10 days resulted in dose-proportional increases in hFVIII antigen levels. In conclusion, we have demonstrated the feasibility of a non-viral approach using novel LNPs for treating severe bleeding disorders using the super pigyBac DNA insertion system, with the potential for repeat dosing.

946 Preclinical Development of an Adeno Associated Vector-Based Gene Therapy (SENS-501) for the Autosomal Recessive Non-Syndromic Deafness 9 (DFNB9)

Guillaume Olivier[1], Christophe Tran Van Ba[1], Lise Barrot[1], Rafik Boudra[1], Julie Duron Dos Reis[1], Pierre Rambeau[1], Charlene Vaux[1], Sandra Pierredon[1], Anais Riviere[1], Pauline Liaudet[1], Audrey Broussy[1], Anne-Gabrielle Harrus[1], Selma Dadak[1], Saaid Safieddine[2], Jerome Nevoux[3], Ghizlène Lahlou[2], Natalie Loundon[3], Christine Le Bec[1], Emilie Bousquet[1], Marie-Jose Lecomte[1], Christine Petit[1], Arnaud Giese[1], Laurent Desire[1]

[1]Sensorion, Montpellier, France,[2]Institut Pasteur, Paris, France,[3]APHP, Paris, France

Background: Autosomal recessive genetic forms (DFNB) account for most cases of profound congenital deafness. We focus here on the *Otoferlin* gene underlying DFNB9, one of the most frequent genetic forms of congenital deafness. Otoferlin is a calcium sensor protein critical for the transmission of the signal from inner hair cells (IHC) to the spiral ganglion neurons. DFNB9 is caused by pathogenic biallelic loss of function variations in *OTOF* gene leading to the failure of synaptic transmission, resulting in congenital severe-to-profound auditory neuropathy. Cochlear implantation is the only option proposed to young patients thus far. Although this medical device improves the quality of life and language acquisition, hearing quality is limited, and a treatment for DFNB9 is necessary to address this unmet medical need. **Method:** We have developed SENS-501 as a dual AAV (Adeno Associated Virus) approach using two different recombinant vectors, one containing the 5' and the other the 3' portions of *Otoferlin* cDNA. SENS-501 was delivered into congenitally deaf DFNB9 mutant mouse inner ears through the round window at different doses. The therapeutic candidate, and a FLAG-tagged surrogate, was validated through demonstration of *Otoferlin* expression and integrity upon reconstitution of the full-length sequence in vitro and in vivo both in mice and NHP using immunohistochemistry. Dose-response experiments, early biodistribution studies after intracochlear injection were performed in mice and non-human primates (NHP). In primates, the surgical method and the delivery device were the ones envisioned in human. Biodistribution studies were conducted by qPCR and RT-qPCR. The reversal of the deafness phenotype in *Otof*$^{-/-}$ mutant mice was evaluated through the assessment of auditory brainstem response (ABR) recordings after intra-cochlear administration either pre-hearing onset, or post-hearing onset and acoustic startle test, a behavioral test allowing to demonstrate efficient auditory processing. **Results:** IHC-restricted *Otoferlin* expression and good preliminary tolerability were demonstrated in both mice and NHP. Post-natal intracochlear injection of SENS-501 into the DFNB9 mutant mouse

inner ear led to improvement of hearing thresholds and behavioral response as early as 3 weeks post-injection. Long-term ABR recovery was achieved in a dose dependent manner, with efficacy demonstrated for at least ten months. Dose-range, early biodistribution, as well as preliminary safety studies including immunogenicity with SENS-501 helped to design the ongoing GLP toxicity and biodistribution studies. **Conclusions:** SENS-501 appears safe and well tolerated. The selected AAV vector components allow to efficiently target IHC at levels compatible with therapeutic intervention in human and provide long-term efficacy data in DFNB9 mutant mouse model, which constitute a major step toward our future clinical trials to restore physiological hearing in DFNB9 patients.

947 Stable Producer Cell Lines for Production of Lentiviral Vectors for CAR T Cell Therapies

Richard W. Beswick[1], Joana Boura[2], Kirstie Pemberton[1], Maria Kapanidou[1], Radmila Todoric[1], Jordan Wright[2], Dan C. Farley[2], Carol Knevelman[2], Nicholas Clarkson[2], Kyri Mitrophanous[2], Lee Davies[1], Hannah J. Stewart[1]

[1]Oxford Biomedica (UK) Limited, Oxford, United Kingdom,[2]Oxford Biomedica, Oxford, United Kingdom

The market approval of chimeric antigen receptor (CAR) T cell therapies together with the continuous emerging number of CAR-based ex-vivo and in-vivo targeted products in development has created increased demand for the supply of large quantities of high-quality grade lentiviral vectors (LVV). Production of LVV using producer cell lines (PCLs) is desirable due to reduced costs, improved batch consistency and further up-scaled and streamlined production processes when compared to LVV produced by the standard transient transfection manufacturing process. However, the development of PCL LV-CAR cells lines has been extremely challenging as it was found that constitutive expression of the CAR molecules often elicits a detrimental effect on the survival of PCLs capable of producing high titre LVV. The combination of an improved version of the TRiP system™ able to efficiently repress CAR expression in a stable cell line, with a well-established cell line development platform, have enabled the successful generation of high titre suspension PCL LV-CAR clones with accelerated timelines. To complement this, a new manufacturing process has been developed, which takes advantage of advances in perfusion technology to support LVV production at higher cell densities than those associated with traditional batch and fed batch production approaches. This new process has been scaled to 5L bioreactors using PCLs, delivering a significant improvement in LVV-yields compared to batch processes and with equivalent downstream recoveries. As such, this new process represents the next generation of LVV manufacturing processes, yielding high LV-CAR titres from inducible PCLs at large-scale. It is anticipated that this PCL LVV production platform will support increased yields at reduced cost enabling more patients to be treated with these life changing cell and gene therapies.

948 Profiling the Tropism of AAV Variants for Various Mouse Tissues Using Directed Evolution

Subin Cho[1], Hongyoung Choi[2], Soonil Kwon[2], Jinyoung Kim[1], Yoojin Kim[1], Zheng Rong Lau[1], Sung Jin Lee[2], Hong kee Kim[2], Jae-Hyung Jang[2], Changmin Kang[2]

[1]Yonsei University, Seoul, Korea, Republic of,[2]Glugene Theraputics, Seoul, Korea, Republic of

Recently, adeno-associated virus (AAV)-mediated gene therapy approaches have emerged as a promising and effective means for treating a variety of incurable human diseases due to their safety and delivery efficiency. However, naturally occurring AAVs have a problem with off-targeting due to broad tissue specificity, which limits administration routes and reduces stability. Directed evolution can efficiently identify more specific AAV variants for particular tissues, addressing the off-targeting problem of wild-type AAVs. We attached a 25 bp nucleotide barcode sequence to a library of AAV capsid variants, created through error-prone PCR, to determine their specificity for various tissues. The barcode was uniquely matched to each capsid molecule in the library and used for nanopore sequencing, a next-generation sequencing method, after *in vivo* selection during the directed evolution process in mice. These results allowed us to establish an AAV capsid gene mutation profile for each mouse tissue.

949 Structure Function Correlates of New AAV Variants Evolved in Human Brain Explants

Aaron M. Mitchell-Dick[1], Michael Adoff[2], Emily J. Kang[1], Sylvanie Clouden[1], Derek G. Southwell[3], Aravind Asokan[4]

[1]Surgery, Duke University, Durham, NC,[2]Neurobiology, Duke University, Durham, NC,[3]Neurosurgery, Duke University, Durham, NC,[4]Duke University, Durham, NC

Adeno-Associated Virus (AAV) is a commensal virus in mammals that has shown significant promise as a vector for human gene therapy. A major challenge facing effective clinical translation is the species-specific variations in tropism and efficiency across both natural and novel AAVs. The AAV capsid and genome regulatory elements are critical determinants of vector performance. In particular, data in human tissue are scarce, and our understanding of transduction in human CNS cell types is still developing. Here we take steps to unravel AAV capsid biology in human brain tissue by cycling multiple AAV libraries based on serotypes 6,8, and 9. Briefly, enabled by an IRB approved protocol following patient surgery for intractable epilepsy, we subjected patient-donated, resected cortical tissue to AAV library cycling. Newly evolved AAV variants obtained from the human cortex demonstrated markedly improved transduction in brain slice cultures. We observe serotype and variant capsid-dependent patterns of widespread, pan-neuronal to glial transgene expression. Notably, we identify different capsid surface domains contributing to improved transduction efficiencies in primary human neurons and ability to penetrate deeply within cortical slices. We also confirm robust gene transfer of several human cortical tissue-derived AAVs compared to natural serotypes in mice following intracerebroventricular injection. Further, using transcriptomic analysis of barcoded AAV capsids in human cortical slices and the mouse brain, we bridge structural

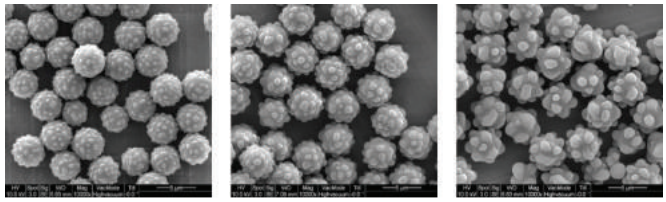
determinants with observed cellular tropisms. Understanding AAV vector biology in human tissues alongside other preclinical animal models could improve predictive modeling and clinical translation of CNS gene therapies.

950 A Novel Feeder-Free Platform for Immune Cell Manufacturing

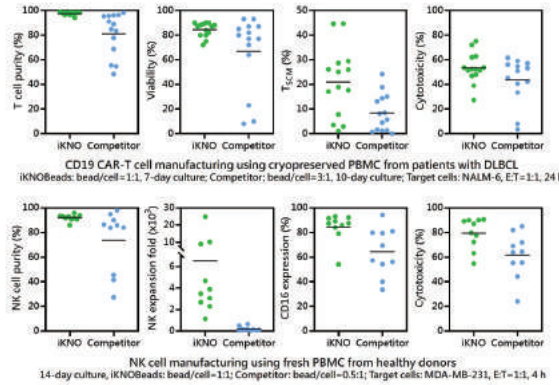
Cheng-Tai Chen, Chien-An Chen, Wen-Ting Chiang, Nien-Tzu Chou, Chih-Hung Lee, Su-Feng Chiu, Ching-Fang Lu

Biomedical Technology and Device Research Laboratories, Industrial Technology Research Institute, Chutung, Taiwan

In recent years, cellular immunotherapies have revolutionized the strategy for cancer treatment. Antibody-coated magnetic beads have become the most widely used artificial antigen-presenting cells (APCs) for CAR-T cell manufacturing, and all the commercially available products are spherical in shape. Inspired by the natural morphology of dendritic cells, micrometer-sized magnetic beads with tailorable sizes and shapes were fabricated for the first time, named iKNOBeads. The bumpy body creates a larger contact area for cell interactions, which improves activation efficiency and reduces the amount of beads used. The reactive functional groups grafted on the polymeric surface make it easy to modify various stimulatory ligands. The uniformity of bead size provides batch-to-batch reproducibility. The magnetic property of beads allows for ease of separation. Based on the advantages of iKNOBeads, we have successfully developed a 7-day process for CAR-T cell manufacturing. In a DLBCL-patient study, CAR-T cells exhibit higher purity, quality, and in-vitro cytotoxicity than the product manufactured by a 10-day process using commercial magnetic beads. Natural killer (NK) cells are emerging as a candidate for next-generation allogeneic cell immunotherapy. Genetically engineered feeder cells enabling an effective expansion of NK cells have become the market's mainstream. However, there are safety concerns regarding contaminating cells in the final therapeutic product. We have screened numerous stimulatory candidates to be modified and proved that iKNOBeads has enormous potential for NK cell manufacturing. In a healthy-donor and breast cancer-patient study, the expansion capability, purity, and cytotoxicity of NK cells expanded with iKNOBeads are superior to that of commercially available feeder-free products and are comparable to that of feeder cells reported. These results show that iKNOBeads offers a more effective and economic feeder-free platform for generating high quality and quantity immune cells for therapy. GMP-compliant production of iKNOBeads has been established for clinical applications.



Electronic microscopy images of the core of iKNOBeads



951 Single-Cut Gene Editing Therapy for Duchenne Muscular Dystrophy via a Single AAV Vector

Guoling Li[1], Jiajia Lin[2], Haisen Li[1], Ming Jin[2], Zhifang Li[3], Linyu Shi[1], Ning Wang[2], Wanjin Chen[2], Hui Yang[1,4]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China,[3]Lingang Laboratory, Shanghai, China,[4]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Duchenne muscular dystrophy (DMD) is an X-linked fatal disease arising from genetic mutations in the *DMD* gene and has become the most common neuromuscular disorder in childhood whose global prevalence reaches 1 in ~3500 male births. However, there is no curative therapy for this devastating disease at present. Among thousands of DMD-causing mutations, the skipping and reframing of exon 51 are estimated to therapeutically benefit at least 14% of all DMD cases worldwide. Thus far, an antisense oligonucleotide medicine (also known as Eteplirsen) has been approved to treat DMD patients with particular mutations in the exon 45-55 hotspot region by promoting dystrophin production and restoring the translational opening reading frame (ORF) of DMD through exon 51 skipping at the transcription level. However, Eteplirsen-treated patients had mean increase in dystrophin protein expression at 0.22 - 0.32% of the normal levels after 48 weeks of weekly intravenous infusion. The wide application of Eteplirsen is greatly limited by many factors such as high cost, short half-life, and poor delivery efficiency to the heart. Therefore, there is a huge unmet medical need to explore innovative yet efficient therapeutic approaches to correct genetic mutations and restore dystrophin expression and muscle functions in individuals with DMD. **Methods**: Humanized DMD mice were generated using targeted deletion of mouse exon51 and exon52 via replacement with human exon51, which disrupted the dystrophin ORFs. We explored the efficiency of proprietary hfCas12Max-mediated single-cut genome editing in human *DMD* exon51 splice donor (SD) site *in vitro,* and an all-in-one AAV vector system was chosen for in vivo delivery of hfCas12Max and a gRNA targeting the SD site of human exon51 to manifest the *in vivo* single-cut efficiency. **Results:** The genetically humanized DMD mice exhibited highly similar phenotypes with that of humans and were suitable for subsequent analysis of potential interventions strategies. There was a high efficiency of hfCas12Max-

mediated single-cut genome editing in human *DMD* exon51 SD site *in vitro*. Systemic *in-vivo* hfCas12Max gene editing efficiently restored dystrophin expression and ameliorated pathologic hallmarks of DMD, including histopathology and grip strength in this mouse model (Fig. 1). **Conclusions**: This unique DMD mouse model with the human genomic sequence allows *in vivo* assessment of clinically relevant gene editing strategies as well as other therapeutic approaches. Research on improving present antisense-based therapeutic strategies represents a significant step toward therapeutic translation of gene editing correction of patients with DMD.

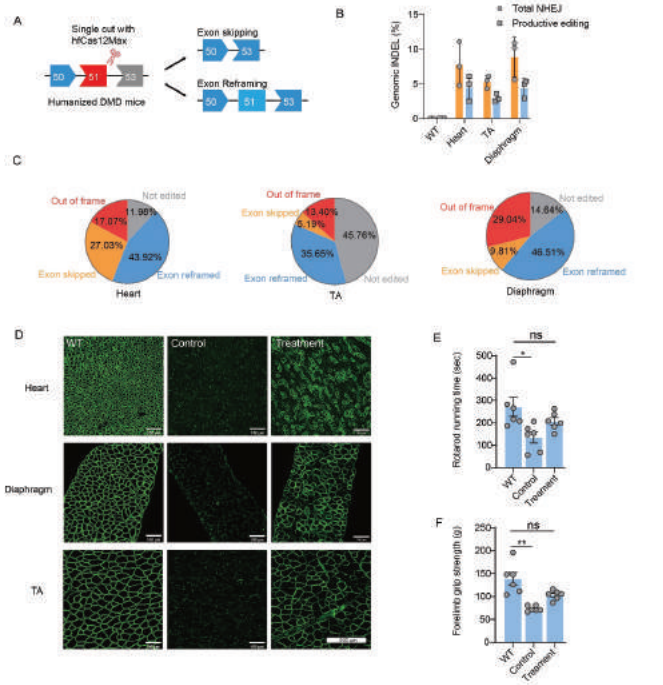


Figure 1. Efficient *in vivo* restoration of dystrophin expression and muscle functions by hfCas12Max in the humanized DMD mouse model
A, hfCas12Max-mediated single-cut gene editing strategy was designed to restore the open reading frame of the dystrophin gene by exon skipping and exon reframing. B, The percentages of genomic editing indels in the heart, TA and DI from DMD mice treated with AAV or saline. C, Deep sequencing analysis of RNA from the heart, TA, and DI of AAV- or saline-treated humanized DMD mice. D, Immunohistochemistry analysis of dystrophin expression in the heart, DI, and TA of WT, DMD mice infused with AAV or saline. Dystrophin was shown in green. Scale bars, 200 μm. Rotarod (E) and forelimb grip strength (F) were measured in WT, DMD mice with AAV or saline treatment. Data shown as mean ± SEM. Significance was indicated by the asterisk. Different asterisk represented the statistical significance among multiple groups by ANOVA.

952 An Open-Label, Dose-Escalation, Phase 1a Study to Evaluate Safety, Tolerability, and Exploratory Efficacy of Intravenous Injection of Allogenic Early-Passage Mesenchymal Stem Cells (MSCs), Derived from Wharton's Jelly in the Umbilical Cord, in Patients with Duchenne Muscular Dystrophy

Jeehun Lee

Pediatrics, Pediatric Neurology, Samsung Seoul Hospital, Sungkyunkwan University, Seoul, Korea, Republic of

Introduction Duchenne Muscular Dystrophy (DMD) is a genetic disease with progressive muscle degeneration caused by mutations in the dystrophin gene. As an X-linked recessive disease, it affects approximately 1 out of every 5,000 male infants and about 20,000 newborns worldwide each year. The study was an open-label, dose-escalation, phase 1a clinical trial in DMD patients with EN001, a next-generation stem cell therapy. EN001 is an allogeneic early-passage MSC derived from Wharton's Jelly in the umbilical cord which demonstrated a high treatment efficacy for DMD in preclinical studies. Objective To evaluate the safety, tolerability, and exploratory efficacy of EN001. Methods A total of 6 male participants aged between 2 to 18 years who were genetically confirmed as DMD enrolled in a 12-week study and a long-term (5 years) follow-up study. Three participants received EN001 with a low-dose (5.0x105 cells/kg) once and the other 3 participants with a high-dose (2.5x106 cells/kg) once intravenously on Day 1.Adverse events with a grade 3 or higher in national Cancer Institute Common Terminology Criteria for Adverse Event (NCI-CTCAE) were defined as a dose-limiting toxicity (DLT) during the first 2 weeks after the EN001 administration. Serum creatine kinase (CK) level, North Star Ambulatory Assessment (NSAA), Six Minute Walk Test (6MWT), muscle strength, and pulmonary function were measured within the 12 weeks study period to evaluate the exploratory efficacy. Results DLTs nor serious adverse events (SAE) were not observed in a 12-week study. And Infusion-related reactions were not observed. Six treatment-emergent adverse (TEAE) events were reported as mild and the patients recovered within 5 days from the onset.Interestingly, decrease in the level of serum CK was observed during the study period in all patients. In NSAA, one patient in the low-dose group showed an improvement from 1 (Modified method but achieves goal with no physical assistance) to 2 ('Normal' - no obvious modification of activity) in item 11 "Gets to sitting", and a patient in the high-dose group revealed improvement from 0 (Unable to achieve goal independently) to 1 (Modified method but achieves goal with no physical assistance) in both item 6 "Climb box step - right" and item 9 "Descend box step - Left". The overall score of all patients was not changed compared to the baseline, which may indicate that the progression of the disease was delayed. In addition, two patients in the low-dose group and one patient in the high-dose group showed improvement in forced vital capacity in the Spirometry. The muscle strength of the left knee extensors was improved in one patient in the low-dose group and two patients in the high-dose group, and that of the right knee extensors was improved in all 6 patients. Conclusions EN001 was safe and well-tolerated at both low-dose (5.0x105 cells/kg) and high-dose (2.5x106 cells/kg) for DMD patients. In addition, the data on treatment efficacy indicates that EN001 improved ambulatory capacity, pulmonary function, and muscle strength in some patients.This study suggests that allogeneic early-passage MSCs derived from Wharton's Jelly might have a potent therapeutic effect for DMD treatment and can be used in all subtype-specific DMD patients.

953 A Streamlined AAV Purification Process by Direct Loading of Filtrated Harvest Materials onto an Affinity Chromatography Column

Huan Xu, Stella Ju, Jenny Zhao

Forecyte Bio USA Limited, Frederick, MD

GMP, clinical grade, adeno-associated virus (AAV) vectors used in various modalities such as gene therapies and vaccines, need to meet stringent quality and purity standards for clinical use. Generally, the downstream processing of AAV products involves cell lysis, depth filtration, and ultracentrifugation/diafiltration (UFDF) before loading onto an affinity chromatography column. The UFDF unit operation often utilizes expensive membrane cartridges, complex equipment, and results in long processing time due to slow filtration speed and

large harvest volume. We developed a simplified AAV downstream processing and purification platform which does not include the UFDF operation. The clarified AAV harvest is loaded directly onto an AAVx or AVB column. This process platform has been tested on various AAV serotypes such as AAV 2, 5, 6, 8, 9 and DJ. The purification step yield and removal of impurities, such as host cell proteins, nucleases, and residual DNA for the simplified purification process were evaluated. Using an enhanced column cleaning procedure, the purification efficiency and binding capacity of AAVx affinity resin were not affected by this simplified, direct loading method. As the result, our improved downstream AAV purification platform is shown to not only achieve a similar or higher product yield, but also use less time, with lower cost and labor compared to a general process with a UFDF step.

954 Modeling Antigen-Specific CAR T-Cell Inhibitors in Nonhuman Primates

Lucy Maynard[1,2], Nikhita Poole[1], John Bui[1,2], Carly Starke[1], Jesenia Atherley[1], Hans-Peter Kiem[1,2], Christopher W. Peterson[1,2]

[1]Fred Hutch Cancer Center, Seattle, WA,[2]University of Washington, Seattle, WA

Introduction: Translating successful chimeric antigen receptor (CAR) T-cell therapies from B cell malignancies to solid tumors and infectious diseases has proven challenging. To identify factors associated with successful and suboptimal strategies *in vivo*, we have developed respective nonhuman primate (NHP) models of CD20$^+$ B-cell-specific and HIV-1-specific CAR T-cell therapies. Our HIV model is designed to overcome inefficient CAR-mediated clearance of latently infected cells in secondary lymphoid tissues by boosting CAR T-cells with cell-associated viral Envelope (Env) protein *in vivo*. Here, we used NHP B cell-specific CAR T-cells as a benchmark to identify barriers associated with HIV-specific CAR T-cell trafficking to tissues, recognition of target antigen, and impacts of cell-free vs. cell-associated antigen. **Methods:** A total of 23 rhesus macaques were infected with one of 2 HIV-like viruses to model lower and higher levels of viral antigenemia, then suppressed by antiretroviral therapy (ART) for at least 7 months prior to HIV-specific CAR T-cell dosing. CAR infusion was followed by infusion of irradiated antigen-expressing cells (K562-Env), and ART cessation leading to rebound viremia. To support CAR T cell persistence in low-antigen environments, we also evaluated i) co-infusion of T cells expressing 4-1BB- and CD28-based CARs, and ii) arrayed CRISPR-edited CAR T-cells designed to overcome immune exhaustion. CAR expression and trafficking was quantified via direct immunolabeling of the CAR molecule, ELISA assays quantified humoral responses to antigen boosting, and next generation sequencing was used to measure persistence of immune checkpoint-edited cells. **Results:** Whereas CD20 CAR T cells consistently expanded and depleted CD20$^+$ B cell targets in NHP, virus-specific CAR T-cell function varied substantially between animals. Manufacturing data and functional assays validated the quality and potency of our respective NHP CAR T-cell infusion products. Cell-associated Env boosting triggered a significant increase in serum anti-Env antibody titers, consistent with *ex vivo* data showing preferential impacts of cell-associated antigen on virus-specific CAR T-cell function. Degree of CAR expansion in peripheral blood was the strongest predictor of target depletion efficiency in our model, which was not impacted by CAR domain structure or CRISPR editing. Intriguingly, we observe only minimal trafficking of CAR$^+$ cells to secondary lymphoid tissues, independent of target depletion efficiency. **Conclusions:** Our unique and highly informative large animal models draw sharp contrasts between the *in vivo* function of CAR T-cells in antigen-replete (CD20$^+$ B-cells) vs. antigen-sparse settings (ART-suppressed viral infection). In addition to a paucity of antigen, our evidence suggests that virus-specific CARs must overcome inhibitory effects of cell-free antigen (namely infectious virions) and virus-specific antibodies, which could both interfere with CAR T-cell recognition of cell-associated antigen. Immunocompetent preclinical models such as ours will be essential in order to characterize and overcome suppressive immune microenvironments that may downregulate CAR T-cell function in numerous clinical settings.

955 Classification Modeling to Identify Patients at Risk for Neurotoxicity and CRS Following Axicabtagene Ciloleucel (axi-cel) Treatment in 2nd Line R/R LBCL

Kelly Speth, Qinghua Song, Justin Budka, Mike Mattie, Shilpa Shahani, Marco Schupp, Debbie Mirjah, Jiali Yan, Jin Xie, Saran Vardhanabhuti, Jeremy Margaitis, Rhine Shen, Simone Filosto

Kite, a Gilead Company, Santa Monica, CA

Background: Axi-cel is an autologous antiCD19 chimeric antigen receptor T-cell therapy approved for the treatment of relapsed or refractory large B-cell lymphoma after ≥1 lines of systemic therapy. ZUMA-7, a global Phase 3 randomized study, showed superiority of axi-cel over standard second-line therapy (N=359; event-free survival [EFS] HR 0.398, P<0.0001, Locke et al. *NEJM*. 2021). Post-axi-cel cytokine release syndrome (CRS) and neurologic events (NE) were reported in 92% and 61% of patients, and rates of high-grade (Grade 3+) events were 6% and 21%, respectively. While the pathophysiology of CRS is well documented, the mechanisms underlying NE remain elusive. Hence we investigated biomarkers and classification models to identify *a priori* those patients more likely to experience high-grade post-axi-cel NE toxicity - as well as patients who may experience low/no post-axi-cel toxicity and may be amenable to treatment in the outpatient setting.**Methods:** For classification models, we considered biomarkers collected at baseline (i.e., prior to lymphodepletion) or on Day 0 (prior to axi-cel), which included demographics, clinical and disease characteristics, routine blood chemistry and hematology, cytokines and other pharmacodynamic (PD) markers, and product attributes. To account for the impact of lymphodepletion, we further examined fold changes of routine lab and PD markers between baseline and Day 0. Multiple machine learning methods (e.g., conditional random forest, XG Boost) were used to select features of interest for classifying patients by outcomes, where a data-driven approach was implemented (i.e., a set of presumed clinically-relevant biomarkers was not selected *a priori*). A logistic classifier was trained and performance measures were evaluated in the hold-out test set (70%-30% split).**Results:** Thirty-six of the 170 axi-cel-treated patients (21%) experienced Grade 3+ NE post-axi-cel. Sixty-seven (39%) axi-cel-treated patients had low toxicity defined as a maximum of Grade 1 CRS and no NE within 7 days post-axi-cel. We determined that top-performing models for

high-grade NE (Grade 3+) include between 3 and 5 biomarkers (e.g., standard clinical labs and disease characteristics) and have a high negative predictive value (NPV; mean NPV in test set: 0.94; 90% empirical CI: 0.90-1.0), while also achieving high sensitivity (mean in test set: 0.88; 90% empirical CI: 0.80-1.0). Best-performing classifiers for low-grade toxicity included between 3 and 6 biomarkers (e.g., PD markers and product features) and had modest positive predictive value (PPV: mean PPV in test set: 0.69; 90% empirical CI: 0.54-0.87), and achieved encouraging specificity (mean in test set: 0.86; 90% empirical CI: 0.66-0.97). Top-performing models across both outcome definitions achieved reasonable overall classifier performance, with area under the receiver operating characteristics curve in the holdout test set of 0.76 and 0.70, respectively.**Conclusions:** While it remains a challenge to predict which patients will experience high-grade NE toxicity, we have achieved good performance in prospectively identifying those patients who are not likely to experience high-grade NE toxicity. Our best-performing classifiers for low-grade toxicity had modest PPV but encouraging specificity, with reasonable overall classifier performance. Our modeling work can support clinicians in prospectively managing patients who may be at risk for toxicity, as well as those patients for whom outpatient monitoring may be desirable.

956 Generation and Characterisation of a Novel Mouse Model for Mucopolysaccharidosis Type IVA

Margherita Berti[1], Stefania Crippa[2], Raisa Jofra-Hernandez[1], Ludovica Santi[1], Giada De Ponti[1], Gaia Alberti[1], Marilena Mancino[1], Tommaso Basini[1], Serena Scala[1], Pamela Quaranta[3], Luca Basso-Ricci[1], Ilaria Visigalli[4], Giada Zambomini[4], Rossana Norata[5], Martina Rocchi[5], Francesca Sanvito[5], Simona Bolamperti[6], Isabella Villa[6], Patrizia D'Adamo[7], Antonello Spinelli[8], Alessandro Aiuti[9], Maria Ester Bernardo[10]

[1]SR-TIGET, Milan, Italy,[2]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milano, Italy,[3]SR-TIGET (Academic), Milan, Italy,[4]Good Laboratory Practice (GLP) Test Facility, SR-TIGET, Milan, Italy,[5]Pathology Unit, Department of Experimental Oncology, IRCCS San Raffaele Scientific Institute, Milan, SR-TIGET, Milan, Italy,[6]Osteoporosis and Bone and Mineral Metabolism Unit, San Raffaele Scientific Institute, SR-TIGET, Milan, Italy,[7]Mouse Behavior Facility, San Raffaele Scientific Institute, Milan, SR-TIGET, Milan, Italy,[8]Preclinical Imaging Facility, San Raffaele Scientific Institute, Milan, SR-TIGET, Milan, Italy,[9]San Raffaele Telethon Institute for Gene Therapy (SR-TIGET), Milan, Italy,[10]San Raffaele Telethon Institute, Milan, Italy

Mucopolysaccharidosis type IVA (MPSIVA) is a lysosomal storage disease (LSD) caused by mutations in the *Galns* gene with consequent deficiency of N-acetylgalactosamine-6-sulphate sulphatase (GALNS) enzyme. As a result, progressive accumulation of Keratan Sulphate (KS) and Chondroitin-6-Sulphate (C6S) is observed in tissues, clinically translating in severe skeletal phenotypes and growth delay. The enzyme-replacement therapy is the only registered treatment for MPSIVA, though not curative. Based on previous pre-clinical and clinical data obtained for other LSDs in our institute, an *ex-vivo* gene therapy (GT) approach could represent a definitive therapeutic option for MPSIVA patients. However, development of innovative therapies appears challenging since currently available murine models are not sufficiently representative of the human skeletal phenotype. For this reason, we propose to establish and characterise a new MPSIVA mouse model by CRISPR-Cas9 using gRNAs targeting the *Galns* locus in C57BL6/N mice. We obtained five different genotypic variants for *Galns* deletion ($Galns^{-/-}$), which are being evaluated using biochemical (enzymatic activity, KS accumulation), morphological (length measurement, weight gain, CT-scan), behavioural (rotarod, grip and footprint tests) and histopathological parameters to select the $Galns^{-/-}$ model with the most representative skeletal symptom. Additionally, we have investigated the organ-associated inflammation by monitoring the expression of a panel of inflammatory markers. Biochemical analyses have confirmed all $Galns^{-/-}$ to have no Galns activity, whilst KS accumulation has been detected in the peripheral blood of two of our $Galns^{-/-}$variants at 4 months of age. However, only one out of four showed clear signs of skeletal disease, mirrored by a reduced weight gain over time and shorter long bones on CT-scan analysis. In line with these results, the same $Galns^{-/-}$ variant showed differences in bone resistance and cortical composition on pQ-CT screening and appeared weaker when monitored by a grip-strength test. Preliminary evaluation of organ-specific inflammation has highlighted an upregulation of several inflammatory markers in the spleen of all our $Galns^{-/-}$ models. Overall, these results will lead to identify the most representative MPSIVA mouse model for further development of a novel lentiviral-based *ex-vivo* GT, while highlighting cellular and molecular mechanisms behind MPSIVA progression.

957 Adjuvanted Protein Vaccines Boost the Strength and Breadth of the Immune Response Elicited by RNA Vaccine Priming

Jiho Kim[1], Jenn E. Davis[1], Bryan Berube[2], Sean A. Gray[1], Darrick A. Carter[1]

[1]PAI Life Sciences, Seattle, WA,[2]HDT Bio Corp, Seattle, WA

Immunological adjuvants commonly used in conventional protein-based vaccines usually target TLRs and other immune sensors to boost the cellular and/or humoral immune response to the vaccine immunogen. These adjuvants represent a powerful but economic and rapid way of boosting vaccine efficacy. With the advent of RNA vaccines and their meteoric rise, the use of adjuvants enhance the impact of RNA and protein vaccines on disease transmission in low-resource environments and by broadening the immune response address the need for constant revaccination to protect against emerging pathogen variants. Four different formulations of a proprietary TLR4-targeting adjuvant (EmT4™; Oil-in-water emulsion, LiT4Q™; Liposomal, MiT4™; Micellar, AlT4™; Alum-adsorbed) were tested in combination with a SARS-CoV2 spike protein, overlapping peptide pools, and RNA to test their effectiveness in enhancing the immune response in mice. In an initial experiment involving a SARS-CoV2 D614G spike protein prime and boost in C57BL6 mice, the addition of any of the TLR4 adjuvant formulations resulted in increased strength of the antibody response against the homologous SARS-CoV2-S immunogen, with the highest IgG endpoint titers reaching up to 2,000,000 by day 56 post-prime, compared to an average titer of around 41,000 for the unadjuvanted regimen. When tested against the more distant Omicron variant (BA.1), the adjuvanted vaccines exhibited higher IgG titers compared to unadjuvanted protein alone, representing an increased breadth of

response. The best performing adjuvant-spike protein combination resulted in a hundred-fold increased average IgG endpoint titer (2.3×10^5) against omicron spike protein compared to the unadjuvanted protein immunization group (2.8×10^3). Pseudovirus neutralization assays showed a similar trend, with adjuvant-protein combinations showing greater neutralization IC50s compared to unadjuvanted spike protein. Three of the four TLR4 adjuvant formulations which performed the best were selected to use in combination with RNA and peptide-based vaccines in a second phase of the study. To test efficacy of boosting with RNA vaccines, adjuvant + protein or adjuvant + peptide pool combinations were used as the boost after a self-amplifying RNA vaccine (saRNA) prime. Initial results show that the inclusion of adjuvant boosted strength in the systemic IgG response against spike proteins of multiple SARS-CoV2 variants including D614G, Delta and Omicron across all modes of immunization. The adjuvants represent a cheap and quickly implementable addition to vaccine formulation, and could be pursued as a cost-effective modification to vaccines in planning for future pandemic responses. Further research in the immunological mechanisms and cellular response to adjuvanted protein, peptide, and RNA vaccinations is warranted to confirm their efficacy and use in preparation for responses to future pandemics.

958 Accelerated Development of Self-Amplifying RNA (saRNA) Vaccine Candidates Using NxGen Microfluidics

Pierrot Harvie[1], Sadat Sadat[1], Nikita Jain[1], A. Zhang[1], Sijo Chemmannur[1], L. Yee[1], Sri Abbina[2], H. Son[1], Cece Nazaripour[3], Suraj Abraham[1], S. Thampatty[1], D. Menezes[1], A. Shapiro[1], D. Stebbing[1], E. Soon[1], Markwick Karen[1], A. Angell[1], J. Paquette[1], Anna Blakney[4], Lloyd Jeffs[1], Anitha Thomas[1]

[1]Precision NanoSystems, Vancouver, BC, Canada,[2]Precision Nanosystems, Vancouver, BC, Canada,[3]Precision NanoSystems Inc., Vancouver, BC, Canada,[4]Imperial College London, London, United Kingdom

Introduction: The pandemic of COVID-19 remains challenging to control due to progressive emergence of multiple variants of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), despite the availability of several clinically approved vaccines. However, multiple booster doses of existing clinically approved conventional mRNA-based vaccines for human use have shown progress in producing protective immunogenicity against the variants of SARS-CoV-2. Self-amplifying mRNA has emerged as a newly designed mRNA platform that can replicate itself, allowing substantially lower dose for effective immune response. Herein, we demonstrate the preclinical success of saRNA-based vaccines encapsulated in lipid nanoparticles (LNPs), and lab scale manufacturing to GMP scale using microfluidic technology and the immune response against emerging variants of SARS-CoV-2. **Methods:** Novel ionizable lipids were selected from a proprietary lipid library after assessing the physicochemical profiles and biological activity for its use in LNP. The saRNAs were synthesized from in vitro transcription. Full-length SARS-CoV-2 spike protein-encoded saRNA-encapsulated LNPs were manufactured using NxGenTM microfluidic NanoAssemblr technology platform and characterized for hydrodynamic size, polydispersity index (PDI), loading, encapsulation efficiency, and long-term storage stability. The lead saRNA-based vaccine candidates were screened and assessed for protective immunogenic responses including humoral and cell-mediated immunity, following a prime-boost with 4 weeks apart in various animal models. Protective immunogenic responses of saRNA-based vaccine candidates were evaluated in a hamster virus challenge model against SARS-CoV-2 virus. The vaccine candidates were then tested in Rhesus Macaques. Viral neutralization titres for both Delta and Omicron variants were further analyzed. **Results:** saRNAs-encapsulated LNPs produced were in the desired size range of 60- 80 nm with a PDI value below 0.2 and with an encapsulation efficiency over 95%. In respect to both in vivo efficacy and physicochemical properties, neither batch-to-batch variations nor instability of our lead vaccine candidate were identified. Our repeated preclinical investigations exhibited the generation of robust humoral and cell-mediated immune response in both mouse and hamster models. In both animal models, no clinical symptoms or adverse effects were observed. Moreover, the obtained sera of vaccinated mice showed protective coverage for both Delta and Omicron variants. The lead vaccine candidates protected the hamsters from weight loss and an increased lung weight following SARS-COV-2 challenge. Vaccinated hamsters had higher levels of SARS-CoV-2 specific IgG antibodies and reduced viral loads. The immune response seen in small animal models were translated to NHP. **Conclusion:** Overall data provide evidence for safety and efficacy of saRNA based vaccines, and for accelerated development of bench to large scale manufacture of saRNA LNP vaccine candidates using NxGenTM microfluidic technology platform. NxGen platform is fully capable of scaling-up large volumes of LNP-based saRNAs vaccines while retaining Critical Quality Attributes (CQA) of the drug product. In addition, the obtained protective immunity in various animal models from our preclinical studies strongly highlight the value for development of saRNA LNP based vaccines along with mRNA LNPs to be used effectively during a pandemic response.

959 Brain-Directed AAV Gene Therapy Corrects Lethal Neurodegeneration & Improves Locomotor Behaviour in a Mouse Model of CLN5 Batten Disease

Wenfei Liu[1], Amy Geard[1], Giulia Massaro[1], Michael Paul Hughes[1], Mikel Aristorena[1], Olha Semenyuk[1], Ryea Maswood[1], Alexander J. Smith[2], Robin R. Ali[1], Sara Mole[1], Ahad A. Rahim[1]

[1]University College London, London, United Kingdom,[2]King's College London, London, United Kingdom

The neuronal ceroid lipofuscinoses (NCLs), commonly known as Batten disease, are a group of inherited lethal neurodegenerative lysosomal storage disorders. CLN5 disease is caused by mutations in the *CLN5* gene encoding a soluble lysosomal lumen protein with cysteine-based *S*-depalmitoylase activity. Children with CLN5 disease suffer progressive motor dysfunctions, vision loss, seizures and dementia, eventually leading to premature death. It is currently incurable and there is a desperate need for a novel effective therapy. Here we carried out a preclinical study of an adeno-associated virus (AAV) - mediated gene therapy in a transgenic mouse model of CLN5 disease, with comparison of therapeutic efficacy between two different promoters used to control *CLN5* expression.

A single dose of AAV9 vectors carrying the human *CLN5* gene driven by either the CAG or the synapsin promoter was administered via intracerebroventricular (ICV) injecton into neonatal Cln5 mice. Treatment efficacy was evaluated by assessment of neurodegeneration and monitoring of locomotor functions and life span. In a second trial, single-dose AAV9.hCLN5 was delivered ICV into juvenile early-symptomatic Cln5 mice at 4 weeks of age, to assess treatment efficacy of later stage gene therapy intervention in CLN5 disease. Neonatal ICV administration of AAV9 expressing human *CLN5* driven by the neuronal specific synapsin promoter significantly prevented neurodegeneration, improved long-term locomotor functions and extended lifespan of the Cln5 mice. However, such brain-directed gene transfer employing the ubiquitous CAG promoter demonstrated limited therapeutic efficacy. The vector carrying *CLN5* driven by the synapsin promoter showed enhanced efficacy when delivered at a juvenile early-symptomatic stage, also resulting in long-term disease attenuation, which provides a particularly practical case for clinical translation. These results indicate that brain-directed AAV gene therapy can be a promising treatment strategy for CLN5 disease.

960 Developing an AAV-Based Gene Replacement Therapy for Mitochondrial Alanyl-tRNA Synthetase 2 (*AARS2*) Leukodystrophy

Ruxiao Xing, Lingzhi Ren, Nan Liu, Chen Zhou, Jialing Liang, Jiaming Wang, Guangping Gao#, Dan Wang#

Horae Gene Therapy Center, University of Massachusetts Chan Medical School, Worcester, MA

The nuclear *AARS2* gene encodes mitochondrial alanyl-tRNA synthetase 2 that is responsible for attaching alanine onto the cognate tRNA in mitochondria. The resulting alanyl-tRNA participates in mitochondrial translation that produces the key proteins constituting the mitochondrial respiratory complexes. *AARS2* mutations have been implicated in two recessive diseases: infantile cardiomyopathy and late-onset leukodystrophy. Currently, there is no treatment available for *AARS2* related diseases. To develop a potential gene replacement therapy, we generated recombinant AAV9 vectors expressing human *AARS2* driven by a ubiquitous promoter (rAAV9.hAARS2), and injected wild-type (WT) mice to test safety of AARS2 over-expression. We found that systemic delivery to neonatal mice via facial vein injection caused animal death within a week, whereas intracerebroventricular injection was well tolerated. TUNEL assay revealed apoptotic hepatocytes in the animals receiving facial vein treatment, suggesting liver toxicity. Therefore, we modified the expression cassette to include miR122 binding sites that enable liver-specific, miR122-mediated transgene silencing (rAAV9.hAARS2.miR122BS). Indeed, the modified vector design prevented hepatocyte apoptosis and animal lethality following facial vein delivery. To characterize the functional consequences of AARS2 malfunction and establish meaningful biochemical readouts of AARS2 restoration, we obtained fibroblasts from a 16-year-old patient diagnosed with leukodystrophy and carrying compound heterozygous *AARS2* mutations. To our surprise, mitochondrial alanine tRNA charging efficiency was not compromised and mitochondrial function was intact as determined by a deep sequencing-based assay and Seahorse assay, respectively. We have reprogrammed the patient fibroblasts into induced pluripotent stem cells (iPSCs), and are in the process of generating iPSC-derived neurons and oligodendrocytes to study potential cellular defects in the disease-relevant cell types. Furthermore, to generate a mouse model of *AARS2* disease, we knocked in a patient-relevant mutation into mouse *Aars2* gene and obtained chimeric founders. The mutant allele is being tested for germline transmission. Together, our study supports the safety of brain-directed *AARS2* gene replacement therapy and calls for a deeper understanding of the disease pathomechanisms in suitable cellular and animal models. (#Co-corresponding authors)

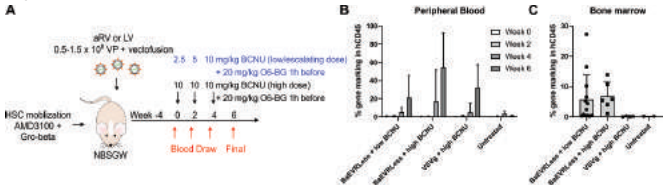
961 *In Vivo* HSC Gene Therapy Using BaEVRLess-Pseudotyped Retroviral Vectors

Denise Klatt[1,2], Boya Liu[2], Adele Mucci[1,2], Marie Peschers[1], Giulia Schiroli[3], Axel Schambach[4], Chad Harris[2], Danilo Pellin[1], John P. Manis[5], Myriam A. Armant[6], David T. Scadden[3], Els Verhoeyen[7], David A. Williams[2], Christian Brendel[1,2]

[1]Dana Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, MA,[2]Hematology/Oncology, Boston Children's Hospital, Harvard Medical School, Boston, MA,[3]Regenerative Medicine, Massachusetts General Hospital, Boston, MA,[4]Experimental Hematology, Hannover Medical School, Hannover, Germany,[5]Transfusion Medicine, Boston Children's Hospital, Boston, MA,[6]TransLab, Boston Children's Hospital, Boston, MA,[7]INSERM/CIRI/EVIR, Lyon, France

In vivo hematopoietic stem cell (HSC) gene therapy has several potential advantages over *ex vivo* gene therapy, such as eliminating the need for stem cell harvest, *ex vivo* manipulation of cells and conditioning of the patient as well as potentially reducing costs. The VSVg envelope glycoprotein is commonly used for pseudotyping of retroviral vectors but is not well suited for *in vivo* application due to its serum sensitivity and poor ability to mediate gene transfer into quiescent HSCs. In contrast, the baboon endogenous retrovirus (BaEV) glycoprotein and its derivative BaEVRLess allow efficient gene transfer into resting HSCs and are serum resistant. The aim of this work is to explore the potential of BaEVRLess-pseudotyped retroviral particles for *in vivo* HSC gene therapy (Fig. A). Competitive experiments revealed that both alpha-retroviral and lentiviral particles can transduce CD34+ cells at similar rates *in vivo* and are suitable for *in vivo* application. To enhance gene transfer, we first optimized the mobilization of HSCs in humanized NBSGW mice. The combination of AMD3100 and Gro-beta efficiently mobilizes HSCs within 60 minutes of drug application in a range of 3-112 hCD34+ cells/μL of blood. 0.5-1 x 10^8 viral particles were injected intravenously into animals after mobilization. Initial gene marking reached up to 3% of hCD45+ cells three days post injection and stabilized around 1% four weeks after *in vivo* transduction. To select for gene marking, we overexpressed MGMT-P140K in transduced cells, which mediates resistance to the alkylating agent BCNU. After three cycles of BCNU treatment, we observed a 20-fold (0.7% to 21.1% GFP+) or 144-fold (0.38 to 54.6% GFP+) enrichment of gene marked cells in the peripheral blood using either a low or a high dose regimen, respectively (Fig. B). In the bone marrow, gene marking reached 5.8% in the low-dose group and 6.8% in the high-dose group (Fig. C). Transduced cells were present in lymphoid and myeloid lineages. We detected 18.1% gene-marked hCD34+ cells in the bone marrow after engraftment. Finally, we combined the MGMT-P140K overexpression with a therapeutic payload by targeting the

transcription factors BCL11A and ZNF410 using miRNA-embedded shRNAs (shmiR) containing vectors. Downregulation of BCL11A and ZNF410 in erythroid cells leads to sustained reactivation of gamma-globin and induction of fetal hemoglobin, which largely attenuates the hematologic effects of sickle cell disease. Following *in vivo* gene transfer and BCNU selection in NBSGW humanized mice, the bone marrow cells were harvested for *in vitro* erythroid differentiation and enrichment of transduced cells via FACS. We observed a significant upregulation of gamma-globin (35.6%) and fetal hemoglobin (25.1%). In summary, we demonstrate the proof-of-principle that BaEVRLess-pseudotyped retroviral particles can be applied for *in vivo* gene therapy, e.g. to treat sickle cell disease.



962 GMP Compliant BACS Microbubble Bag-Based T Cell Isolation in a Closed System CAR-T Manufacturing Workflow

Edward Grimley, William R. Lloyd, Maureen Cary, Brittany MacIntyre, Jesse Chen, Jonathan A. Roussey, Nadia Petlakh-Co, Ryan Chandler, Liz Ward, Marja Lahteinen, Angela Little, Crisha Barrett, Vanessa Kelchner, Jason S. Ellis, Casey J. Wegner, Brandon McNaughton

Akadeum Life Sciences, Ann Arbor, MI

In order to treat complex diseases such as cancer, scientists developed treatments based on immune cells that have been modified to improve their effector functions, fine-tune their specificity, increase their ability to survive long-term after adoptive transfer, or a combination thereof. Chimeric antigen receptor (CAR-T) cells represent one version of this. An important early step in the manufacturing of CAR-T cell-based therapies involves the isolation of purified T cells from patient leukapheresis material. Traditionally, this has been accomplished using iron particles and cumbersome magnetic separators. While these methods have a demonstrated utility in the manufacturing of cellular therapies, they have proven difficult to scale and pose a significant financial burden on development programs. In order for the curative potential of cellular therapeutics to be fully realized by patients, disruptive technologies that enable increased manufacturing scale, decreased manufacturing time, and cut overall costs down are vital. Here we present a method for inserting buoyancy activated cell sorting (BACS™) microbubbles into common closed-system CAR-T manufacturing workflows and demonstrate the compatibility of our GMP grade reagent with automated cell processing instruments like the Rotea counterflow centrifugation system. First, leukapheresis material is passed through the Rotea system for washing and platelet removal. Second, an in-bag negative selection of T cells is performed using a novel BACS microbubble cell isolation protocol. Finally, untouched, negatively selected T cells are transferred to a new bag as part of a buffer/media exchange using the Rotea and the isolated cells are then carried through the remainder of the CAR-T manufacturing workflow. This study demonstrates the seamless incorporation of GMP grade BACS microbubbles into existing closed-system workflows without disruption of current manufacturing processes. Using buoyant microbubbles for cell separation allows for quick and gentle isolation of cells, resulting in consistent performance over a wide range of starting leukopak cell compositions. In addition, BACS microbubble isolation yields more purified T cells than traditional methods, and does so in a fraction of the time. The use of next generation microbubble cell isolation enables higher throughput and offers a truly scalable solution to cell isolation. Disruptive technologies such as BACS microbubbles will aid in increased access to cutting-edge cellular therapies for patients across the globe.

963 Novel AAV Constructs for Targeted ApoE2 Delivery Counteracts the Impact of ApoE4 Expression in Amyloid Deposition and Neuroinflammation in Mouse Model of Amyloidosis

Megan S. Keiser[1], Rosemary J. Jackson[2,3], Jonah C. Meltzer[2,3], Dustin P. Fystrada[2,3], David M. Holtzman[4], Beverly L. Davidson[5], Bradley T. Hyman[2,3]

[1]Center for Cellular and Molecular Therapeutics, Children's Hospital of Philadelphia, Philadelphia, PA,[2]Alzheimer Research Unit, The Massachusetts General Hospital Institute for Neurodegenerative Disease, Charlestown, MA,[3]Department of Neurology, The Massachusetts General Hospital and NeuroDiscovery Center, Harvard Medical School, Boston, MA,[4]Department of Neurology, Hope Center for Neurological Disorders, Knight Alzheimer's Disease Research Center, Washington University, St. Louis, MO,[5]Children's Hospital of Philadelphia, Philadelphia, PA

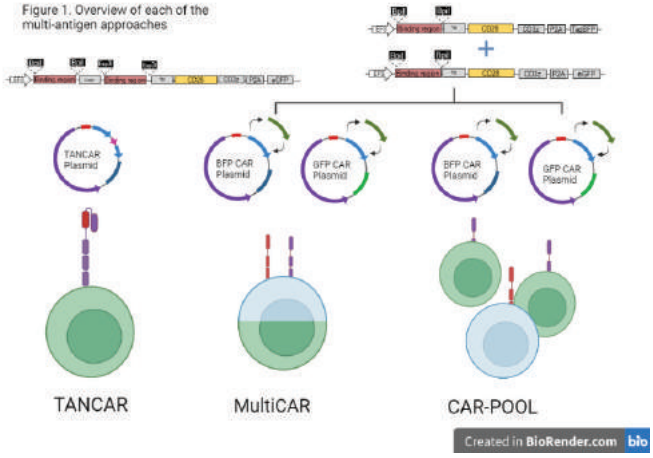
Dementia and more specifically Alzheimer's Disease (AD) pose a global health crisis with more than 3 million cases of AD in the US alone. Inheritance of the ε4 allele of apolipoprotein E (ApoE) is the strongest genetic risk factor associated with the sporadic form of AD, whereas the rare ApoEε2 allele has the opposite effect. However, the mechanisms whereby ApoE confers risk and protection remain uncertain. The ApoEε4 genotype is associated with worsening plaque deposition, increased speed of cognitive decline and increased neuroinflammatory microglia phenotypes. We previously showed that ApoEε4 or ApoEε2 secretion from ependyma after AAV delivery to amyloid plaque-bearing transgenic mice (expressing wild type murine apoE) exacerbated or reduced amyloid plaque burden respectively (Hudry 2013 Sci Trans Med). Here we advance our AAV based gene transfer approach using a novel capsid coupled to a promoter which restricts ApoE2 expression to ependymal cells. When delivered to plaque-bearing mice expressing human ApoE4, and devoid of mouse *apoe* (APP/PS1/mApoE$^{-/-}$/hAPOE4$^{+/+}$) ApoE2 reduced the size and density of cortical amyloid plaques and the concentration of oligomeric Aβ in the brains of these animals. Additionally, we observed reduced microglia activation near plaques indicating that ApoEε4 may prime microglia towards an inflammatory phenotype and that exogenous ApoE2 interrupts or reduces this aberrant activation. Our data support that focused expression of ApoE2 into CSF in ApoE4 carriers may positively impact the classical lesions of AD (eg plaque deposition) as well as the increased neuroinflammatory profile observed in sporadic AD.

964 A High-Throughput Method for the Testing and Optimization of CAR-T Multi-Targeting Approaches

Alex Shepherd[1,2], Scott McComb[1,2], Susanne MacLean[1]

[1]Human Health Theraputics, National Research Council of Canada, Ottawa, ON, Canada,[2]Biochemistry, Microbiology and Immunology, University of Ottawa, Ottawa, ON, Canada

Chimeric antigen receptors (CAR) are fusion proteins which reprogram immune cells to target a specific target antigen when transduced. CAR expressing T-cells (CAR-T) have emerged as an effective treatment method for hematological cancers; however, safely targeting solid tumors has been more difficult. While on target, off tumor toxicity is treatable for hematological cancers, solid tumor antigens overlap with healthy tissue; therefore, requires more precise targeting in order to safely treat patients. Single targeting CAR-T therapy can also be rendered ineffective by tumor mutations such as antigen escape or internalization. By targeting multiple antigens, it is thought that safer and more functional CAR-T therapies can be achieved, but identifying the right combination of antigens and the most optimal combinatorial molecular strategy is a formidable challenge. Here we present the first step in a high-throughput method to screen and optimize multi-antigen CAR strategies. Previously we created modularized CAR plasmids to allow quick and easy recombination of antigen binding domains (ABDs) to create and screen new CAR molecules; here, we sought to extend that platform to screening of multi-antigen targeted CAR molecules. We created a simple set of tools for screening three distinct multi-antigen CAR strategies: Tandem (Two binders, one body), Dual (Two complete CAR proteins on a single cell) and Pool (Two single CARs administered simultaneously or sequentially) and screening their functional activity in high throughput. An overview of this can be seen in figure 1. As proof-of-concept we screened novel binding domains for multi-antigen targeting of hematological malignancies (CD22 and BCMA) or various solid tumors (EGFR and Mesothelin). We found surprisingly variable target responses and tonic activity profiles depending on the specific combination of the ABDs and combinatorial method used. The proof of concept also demonstrated that CAR signaling was maintained though a simulated antigen escape using CRISPR knock-out cells. In primary T cells where differences were amplified, we found that multi-CARs generated through co-transduction consistently outperformed tandem-CAR molecules. In summary, Multi-CAR-J and the related plasmids provide an easy, high-throughput method to assess and compare different methods of combining CARs allowing for an optimal combination of binders with the correct multi-CAR format. We hope to expand this platform from screening to customization, allowing for the future implementation of strategies such as Boolean logic gates, for a safer, more specific CAR treatment.



965 Investigating the Kinetics of Prime Editing

Nathalie Gabriele Schaeffler[1], Julian Geilenkeuser[2], Dong-Jiunn Jeffery Truong[2], Gil Westmeyer[2], Joachim Rädler[3]

[1]Faculty of Physics, LMU Munich, Munich, Germany,[2]Institute for Synthetic Biomedicine, Helmholtz Zentrum München, Neuherberg, Germany,[3]Ludwig-Maximilians-Universität München, München, Germany

Prime Editing (PE) adds a new level of precision to CRISPR based gene editing. It enables efficient search and replace of specific DNA sections without templates or indels and with lower off-target effects. Research in this field currently focuses on optimization of editing efficiency. Although highly optimized PE protocols exist, little regard has been paid to the role of delivery timing and kinetics of Cas9 mediated editing. A good understanding of PE-kinetics is desirable for applications were quantitative control is required including future gene therapies or PE based biocomputing. In our work, we address the question, how the kinetics of PE depends on defined changes in the system, for example, delivery vehicles, vectors or pegRNA variations. To this end, single cell readout is advantageous. As demonstrated in this contribution Live-Cell Imaging on Single Cell Arrays (LISCA, Fig. 1), enables time-resolved tracking of edit events at the single cell level.

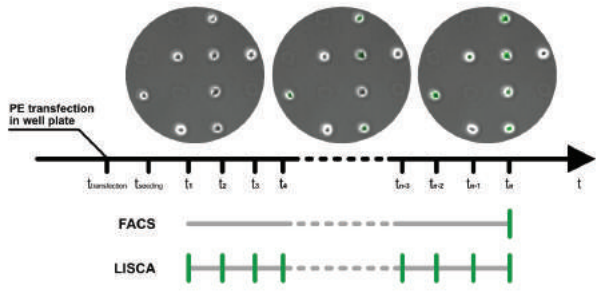


Figure 1: *In our experiments, we measure the fluorescence of single HEK293T cells on a pattern every 15 minutes over 48h, which, compared to the commonly used single time point FACS measurements, gives us a better understanding of PE kinematics.*

As a model reporter system, we use HEK293T cells, which stably express a blue-shifted mGreenLantern (bs-mGL) protein. Only two

base edits in close proximity, i.e. on one pegRNA, are required to change it back to the original mGreenLantern (mGL) sequence. Plasmid transfection of the PE system enables the cells to perform these edits and then express the original mGL protein again. To prepare our experiments, cells are seeded and grown overnight in well plates. They are then co-transfected with both PE2 and a corresponding pegRNA as separate plasmids and incubated until the recommended change of media period has passed. Afterwards, we transfer them to a slide that was patterned for single cell adherence. After an additional incubation period, the slide is loaded on to a fluorescence microscope. Using LISCA, we can then track the green fluorescence signal of single cells over an extended period. This allows us to compare the timing of different pegRNAs, which only differ in actual edit length - first edit to last edit - inside the Reverse Transcriptase template. Using LISCA, we compared the onset times of these pegRNAs, which showed a significant difference (Mann-Whitney-U test, p-value = 1.054e-08, W=1133) during the first 48h, while the FACS measurements interestingly showed them to have a similar efficacy. These differences highlight how pegRNA variations can affect the timing of PE and warrant further studies to investigate similar effects. Gaining a deeper understanding of the kinematics can help us achieve more controlled PE in the future.

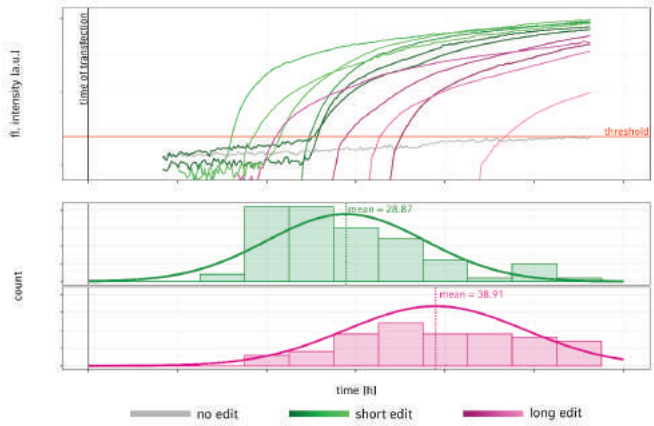

Figure 2: *Fluorescence time courses of single cells over 48h. (1) Fluorescence signal integrated over cell area for presented in logarithmic scale. We define the onset time as the time where fluorescence exceeds the threshold level as indicated. (2) The distribution of on-set times shows a clear shift towards faster editing of short edits compared to long edits.*

966 A Novel Vector for Non-Viral Gene Therapy of Hemophilia A

Ajay Maghodia, Tongyao Liu, Philip Zakas, Susannah Patarroyo-White, Douglas Drager, Qing Yao, Samantha Wilder, Christian Mueller

Genomic Medicine Unit, Sanofi, Waltham, MA

Rare genetic diseases such as Hemophilia are well suited for the gene therapy strategies. First, the expression of clotting factor VIII (FVIII) and factor IX (FIX) gene is not tightly controlled and second, a minimal increase in circulating proteins, even as low as 5% of normal physiological levels, can improve the clinical phenotypes. The current standard of care for Hemophilia A is prophylaxis aimed at increasing FVIII levels to a sufficient level to prevent bleeding episodes and reduce the occurrence of hemarthrosis. Though effective the currently available treatments have limitations of short therapeutic half-life and frequent intravenous infusions, which invokes the development of gene therapy strategies. Recombinant adeno-associated viral (rAAV) vectors are the predominant gene therapy vectors used for several genetic diseases including Hemgenix®, recently approved gene therapy treatment for Hemophilia B patients. However, AAV-mediated gene therapy has several limitations such as pre-existing neutralizing antibody, inability to treat pediatric patients, and a limited cargo capacity, which confines the use of AAV for genetic diseases with a smaller (<5 kb) transgene. Recent advances in vector technology have made the non-viral gene therapy approaches particularly appealing for the chronic diseases such as Hemophilia. The non-viral vectors could potentially circumvent the limitations associated with rAAV vectors and provides the flexibility of inserting a large transgene such as human FVIII together with the regulatory elements such as liver-specific promoter, intron, and transcriptional enhancer for the long-term persistent expression. Typically, non-viral gene therapy uses a plasmid DNA to transfer the transgene of interest into recipient cells. However, the plasmid DNA made in the bacterial system normally contains an antibiotic resistance gene and prokaryotic origin of replication, which potentially triggers an innate immune response upon gene transfer. Besides, there is a significant level of endotoxin contamination in the plasmid DNA prep made from the bacterial system, which could reduce the gene transfer efficiency. Ideally, the DNA for non-viral gene therapy should contain a transgene of interest and lack prokaryotic extraneous sequences as well as endotoxin contamination. The baculovirus-insect cell system (BICS) is a eukaryotic cell-based system that makes it a suitable platform to produce DNA vectors for non-viral gene therapy. In this study to be presented, we utilized the BICS to develop a novel platform technology including, a versatile baculovirus shuttle vector "BIVVBac" bacmid, for non-viral vector production in a form of closed-end DNA (ceDNA). Unlike encapsidated rAAV vector genomes, the ceDNA vector has no packaging constraints imposed by the limiting space within the viral capsid. In this study to be presented, we demonstrated the feasibility of BIVVBac system for non-viral vector (ceDNA) production by using human coagulation factor VIII (hFVIII) together with the regulatory elements such as liver-specific promoter, intron, transcriptional enhancer, and XTEN to enhance the circulating half-life in Hemophilia A patients. Furthermore, we explored the efficacy of several parvoviral ITRs in driving long-term persistence expression of FVIIIXTEN in Hemophilia A mice. The results indicated that the FVIIIXTEN ceDNA persistently produce up to 200% of normal physiological level of FVIII for more than 6 months at 20x lower the dose of other DNA forms tested by the systemic administration in Hemophilia A mice model. Thus, in this study to be presented, we demonstrated the feasibility of our novel vector (ceDNA) for the non-viral gene therapy of Hemophilia A.

967 A Rapid Method with Wide Dynamic Range to Assess Size-Based Purity and Concentration of AAV5 Particles by Size-Exclusion High Performance Liquid Chromatography

Kilian Witzel, Mikaela Vlach, Kenneth Campos, Elie Hanania

Analytical Development (Viral Vectors), Avid Bioservices, Tustin, CA

Background: Monitoring of critical quality attributes (CQAs) is essential to ensure that high quality and well-characterized biological products are manufactured consistently. Size exclusion chromatography (SEC-HPLC) is a rapid analysis method for viral particle quantification that separates them based on their hydrodynamic volume, which generally correlates with size. This allows separation of intact virus particles such as adeno-associated virus (AAV) from other cellular contaminants and fragmented or aggregated virus particles. However, current standard SEC-HPLC methods for virus particles typically have a relatively long run time per injection, a narrow dynamic range, and require high amounts of virus per injection. Here we present a rapid method to adequately quantify monomeric and multimeric AAV particles by SEC-HPLC over a range of four log scales. **Methods:** AAV5 particles were generated internally in HEK293 cells. The capsid titer was determined using Progen AAV5 titration ELISA kit following manufacturer's instructions. ELISA titer results were verified by particle concentration measurement with dynamic light scattering (DLS) using a Malvern Panalytic Zetasizer Ultra Red. Analytical size exclusion high performance liquid chromatography (SEC-HPLC) was performed on a Waters Arc Premier HPLC system PDA and FLR detector. Separation was monitored at 215 nm, 280 nm, and intrinsic fluorescence (ex 280 nm / em 348 nm). A novel Phenomenex Diol SEC column (4.6 x 150 mm, 3 µm) was used at a column temperature of 25°C. Isocratic elution was performed with 20 mM sodium phosphate, 350 mM potassium chloride, pH 6.6. Sample temperature was maintained at 5°C. Samples were diluted formulation buffer. Injection volumes were between 1 and 50 µL. **Results:** Capsid titer of the purified AAV5 particles was determined by ELISA as 2.10E+14 vp/mL. This value was confirmed by an orthogonal DLS. Size-based separation of AAV5 particles was monitored at two wavelengths for UV absorbance and intrinsic fluorescence. Each of these channels monitored has its own range where data was found linear, precise, and accurate (Figure 1). USP resolution between monomeric and multimeric AAV peak was between 1.7 and 1.8 for all injections within the linear range. The percentage of monomeric and multimeric particles were calculated based on the relative percent area of the integrated peaks in each channel. For titer of viral particles, the number of viral particles per milliliter was quantitated from an AAV standard at a predetermined titer. The number of multimeric particles was consistent at 5% over the entire range of the method. **Conclusion:** The method presented here has a significantly improved separation time compared to traditionally used methods (7 min versus 20-30 min per injection). Monitoring of intrinsic fluorescence increases sensitivity over UV detection of proteins. The use of intrinsic fluorescence as well as ultraviolet absorption at 215 nm and 280 nm provides a four-log dynamic range for this method ranging from 5.25E+08 to 5.25E+12 virus particles column load. This HPLC method with multiple monitors creates an opportunity to improve the quality of information to guide development, validation, and monitoring of production processes for AAV virus particles.

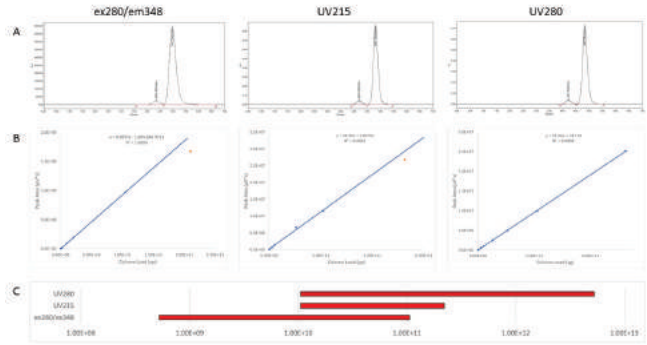

Figure 1: (A) Example chromatograms and (B) linear range at ex280/em348, UV215, and UV280. (C) Detection range of the method.

968 *In Vivo* Time-Course and Tissue-Wide Gene Profiling Reveals Distinct Signatures of CAR-T and CAR-iNKT Cell Responses to Solid Tumors

Miao Li, Yan-Ruide Li, Yuning Chen, Lili Yang

UCLA, Los Angeles, CA

Chimeric antigen receptor T (CAR-T) cell therapy has shown remarkable success in treating blood cancers but only limited efficacy against solid tumors. Lack of knowledge of in vivo behaviors of CAR-T cells, especially in the complex solid tumor microenvironments, is considered as a major hinder hampering the successfully application of CAR-T cell therapy for treating solid tumors. In recent years, unconventional T cells, such as invariant natural killer T (iNKT) cells, have attracted increasing attention as alternative CAR-mediated cell therapy carriers, due to their strong tumor killing capacity, promising solid tumor homing ability, as well as their potential for developing "off-the-shelf" cell therapy. iNKT cells exist in extremely low numbers (0.001-1%) in health donor blood, that greatly limits their clinical applications. To overcome this critical limitation, our lab has developed a new technology to produce therapeutical levels of CAR-iNKT cells through a stem-cell engineering and iNKT differentiation cell culture strategy. Here, we report a study to compare the conventional CAR-T cells with the alternative unconventional CAR-iNKT cells, aiming to obtain an extensive understanding about their in vivo spatial and temporal behaviors against solid tumors. Mesothelium (MSLN) targeting CAR-T and CAR-iNKT cells were administered into NSG mice bearing OVCAR3 human ovarian tumor xenograft. Overtimes, tissues were collected from tumor site and other sites (peripheral blood, spleen and liver); single cells were isolated and subjected to single-cell RNA sequencing (scRNA-seq) analysis. Cells analyzed include the therapeutical cells (CAR-T and CAR-iNKT cells), tumor cells, and tumor microenvironments (TME) cells. Our results revealed several findings. 1) Both CAR-T and CAR-iNKT cells exhibited dynamic gene profiling changes, starting by acquiring an effector/proliferating signature, and gradually transition to progenitor/terminally exhausted gene profiles. These changes happened across all tissues examined, with the changes at tumor site leading the changes at other tissues. 2)

In contrast to CAR-T cells, CAR-iNKT cells displayed significantly enhanced gene profiles that correlated with their stronger in vivo anti-tumor efficacy. 3) CAR-T cells induced immune evasion in tumor site—loss of antigens, while CAR-iNKT cells did not; likely due to their multi-targeting mechanism. 4) CAR-T cells triggered an immunosuppressive and cytokine release syndrome (CRS)-prone TEM while CAR-iNKT cells actively altered TME and reduced CRS gene signatures by eliminating tumor associated macrophages (TAMs). Collectively, our result provides the first-time insight into the in vivo spatial and temporal behaviors of two important cancer cell therapy platforms CAR-T and CAR-iNKT cells. Such knowledge will be valuable for guiding and selecting of proper cell therapy products, and further improving these cell therapies for solid tumors.

969 Abundant Expression of IFNγ by GAIA-102, an Off-the Shelf and Highly Activated NK-Like Cell Product, Induces MHC Class I Expression

Situo Zheng, Harada Yui, Wada Ken-Ichi, Morodomi Yosuke, Yoshikazu Yonemitsu

R&D Laboratory for Innovative Biotherapeutics, Kyushu University Graduate School of Pharmaceutical Sciences, Fukuoka, Japan

Background: We previously established an original method to generate highly activated NK-like cells(GAIA-102) from mixed peripheral blood mononuclear cells from multiple donors. Now three Phase I clinical trials, including neuroblastoma, for assessing the safety and potential anti-tumor activity are ongoing. In the preclinical studies, we found thatGAIA-102 demonstrated the 2-independent anti-tumor mechanism *in vivo,* namely, the induction of not only efficient mass-reduction but alsothe establishment of anti-tumor acquired immunity *in vivo*; however, theunderlying mechanism is still unclear. Malignant tumors escape from $CD8^+$T cell attack through loss of MHC class I (MHC-I) expression, therefore MHC-I upregulation is important for inducing tumor-specificacquired immunity. The purpose of this study, therefore, was to evaluatethe activity of GAIA-102 to upregulate the tumor MHC-I. **Methods:** GAIA-102 was dissolved in Plasma Lyte-A (a clinically available drip infusion) and cocultured with or without K562 cells (CML cell line), and the supernatant was collected. SK-N-SH cells (human neuroblastoma cell line) were treated with the supernatant, followed by surface MHC-I detection using flow cytometry. **Results:** Both the supernatant of GAIA-102 only as well as K562 and GAIA-102 coculture upregulated MHC-I expression of SK-N-SH cells, as increased maximally by 14 folds compared with control. Such effect was diminished in the use of boiled supernatant, suggesting the factor might be a secreted protein, and this effect was completely abolished by IFNγ neutralizing antibodies. The IFNγ concentration in the supernatant of GAIA-102 at 2, 6, and 24 h were 13.0,32.0, and 72.6pg/ml, respectively, and those in the supernatants cocultured with K562 showed approximately 3-fold higherexpression. **Conclusion:** We clarified that GAIA-102 could upregulate the MHC-I expression of tumor cells, by increasing IFNγ secretion in response to tumor cells. We concluded that GAIA-102 might enhance acquired immunity through IFNγ-mediated mechanism.

970 The Retargeted Universal Fusosome: A Modular Approach to Generate Fusosomes for Targeted Gene Delivery

Matteo Stoppato, Katie Sullivan, Jack Reilly, DJ (Dejun) Xuan, Shariq Usmani, Andre DeGroot, Alexander Justen, Albert Ruzo, Kyle Trudeau, Jagesh Shah

Sana Biotechnology, Seattle, OR

In vivo targeted gene delivery has the potential to significantly improve the efficiency and safety of gene therapy for patients. We have previously shown that our gene therapy platform using a retargeted viral vector (fusosome) enables efficient and cell-specific gene delivery to a variety of cell types both *in vitro* and *in vivo*. The fusosome is an integrating viral vector pseudotyped with two viral glycoproteins (that act as a single fusogen) with distinct attachment and fusion functions. The attachment fusogen (G protein) is blinded to its native targets and engineered by fusing a ligand that binds a receptor that is specifically enriched on the surface of a given cell type to generate a G-binder fusion protein. Interaction between this retargeted G protein and its receptor triggers the F protein to mediate membrane fusion resulting in gene transfer from the viral vector to the target cell. Using this approach, we and others have successfully targeted several cell types including hepatocytes and different T cell subpopulations. While this approach works well, our current method requires cloning, expression, and screening of hundreds of different G-binder fusion proteins to identify a few that function well as fusogens in a fusosome. Fusing a binder to the G protein can decrease its surface expression and incorporation into the membrane of the viral vector, potentially disrupting G conformation and functionality, and ultimately reducing the infectivity of the viral particles. Each binder can perturb one or more of these parameters in a unique way requiring extensive screening and optimization to evaluate and identify a lead candidate for each target. To overcome these limitations, we have leveraged a modular approach which eliminates the need for the fusosome production cells to express the G-binder fusion protein; instead, the binder is coupled to the G protein *after* the production of the "Universal Fusosome." This is enabled by addition of a small peptide (adapter) to the blinded G protein. The retargeting binder is fused to a complementary protein that can bind and react with the adapter resulting in an irreversible conjugation. The adapter has been chosen and optimized such that the level of expression and incorporation of the blinded G protein into the viral particles is comparable to that seen for viral vectors pseudotyped with wild type G protein. This design results in a modular system in which retargeting binders can be covalently added to a Universal Fusosome with G levels independent of the binder itself. Here, we present proof of concept data showing efficient and specific gene delivery to a target cell of interest using fusosomes produced by this novel approach. In addition, we demonstrate that this Universal Fusosome coupling approach rescued the suboptimal infectivity observed for several binders when the latter were tested as fusogens using the standard single G-binder fusion protein method. This retargeted Universal Fusosome is a modular system for producing fusosomes for cell-specific delivery. It has the potential to be more time- and cost-effective, removing the need for extensive screening process to identify lead candidates for each target receptor/cell of interest.

971 A Novel Vector for CAR-T Cells with Enhanced Antitumor Response and Reduced Risk of CRS and ICANS

Yasunori Amaishi[1], Izumi Maki[1], Seina Inui[1], Ryosuke Nagata[1], Toshiaki Yoshikawa[2,3], Yuki Kagoya[2,3], Sachiko Okamoto[1], Tatsuji Enoki[1], Junichi Mineno[1]

[1]Technology Development Center, Takara Bio Inc., Kusatsu, Shiga, Japan,[2]Division of Immune Response, Aichi Cancer Center Research Institute, Nagoya, Aichi, Japan,[3]Division of Tumor Immunology, Institute for Advanced Medical Research, Keio University School of Medicine, Tokyo, Japan

CAR-T cell therapies have shown effective antitumor response against hematological malignancies, and several CAR-T cell products targeting CD19 or BCMA have already been approved. However, since relapse occurs frequently and the therapeutic effect on solid tumors is limited, further development of CAR-T cells with long-lasting antitumor response is required. On the other hand, suppression of side effects must also be considered. Cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) are the most frequent side effects, and enhancing the antitumor effect could lead to an increase in these risks. Therefore, it is necessary to develop CAR-T cells with high antitumor response while suppressing serious side effects. Recently, we have developed a novel cytokine receptor that captures IL-6 and IL-1, which cause CRS and ICANS, respectively. Expression of the novel cytokine receptors in CAR-T cells is expected to reduce side effects due to absorption of cytokines secreted by macrophages. In our novel cytokine receptor, we used the extracellular domain of IL-6 receptor alpha chain fused to domains of GP130 to increase the affinity to IL-6, and linked the transmembrane and intracellular domain of the mutated IL-7 receptor alpha chain, which constitutively activates the JKA/STAT pathway while attenuating Akt signaling. Co-introduction of CAR and the chimeric cytokine receptor using individual viral vectors has resulted in long-term in vivo persistence of CAR-T cells and improved therapeutic efficacy. In addition, IL-1 Receptor Type 2 was co-expressed to absorb IL-1 beta in CAR-T cells, and the chimeric cytokine receptor-expressing CAR-T cells could efficiently reduce both IL-6 and IL-1. In order to apply this technology to the clinic, it is necessary to develop a single vector that can highly express individual genes in terms of therapeutic efficacy and cost efficiency. In this study, we have developed all-in-one lentiviral vector to improve and optimize the expression level of each gene. First, we generated lentiviral vectors with various internal promoters and selected the MND promoter as a suitable promoter for CAR-T cells. We then enhanced expression level and function of receptors by codon optimization. When expressing multiple factors in a single vector, the expression balance of each factor is important. Vectors were constructed by switching the order of CAR, IL-6 chimeric receptor, and IL-1 receptor to determine the most functional design. Furthermore, we have confirmed that insertion of woodchuck hepatitis virus posttranscriptional regulatory element (WPRE) in this vector enhanced its function. T cells transduced with the all-in-one vector combining these approaches were used to evaluate therapeutic efficacy in a solid tumor mouse model, and showed significantly enhanced T cell survival compared to standard CAR-T cells, leading to almost complete tumor regression. As a versatile CAR-T platform, this technology promises to be widely applicable regardless of the target antigen to enhance its efficacy and safety.

972 Identification of Novel Mutations in PCCA and PCCB Genes in Fibroblasts from Patients with Propionic Acidemia via Long-Read Sequencing

Rea Guertler, James Maratt, Dana Dusevic, James Sheffield, Elliott Willion, K. Reed Clark, Matthew Fuller

Ultragenyx Pharmaceutical, Cambridge, MA

Propionic Acidemia (PA) is a rare autosomal recessive inherited metabolic disease caused by a deficiency of propionyl-CoA carboxylase (PCC) activity. PCC is a biotin-dependent, dodecameric mitochondrial enzyme comprised of six α (PCCA) and six β (PCCB) subunits that catalyzes the carboxylation of propionyl-CoA to methylmalonyl-CoA. Mutations in either gene can cause PA, which manifests with allelic and genetic heterogeneity throughout both PCCA and PCCB genomic sequences. Fibroblasts from patients with PA (PA fibroblasts) were obtained from the Coriell Institute for Medical Research, which maintains biobanks of patient cells for many diseases for medical research. Unfortunately, for most of these PA fibroblasts there is no available information on the underlying genetic mutations. Here, we used targeted long-read DNA sequencing to identify genomic mutations. We followed-up with PCR-enriched long-read RNA sequencing to confirm the haplotype and suspected splice variants in all eight available cell lines of fibroblast from patients with PA and two unaffected parent fibroblast cell lines. We found that five PA fibroblasts harbored mutations in the PCCA gene and three possessed PCCB mutations. Consistent with the known genetic complexity of PA inheritance, six patients harbored compound heterozygous and two had homozygous mutations. The two parent fibroblast lines were heterozygous for PCCA, and the associated mutations were manifested as compound heterozygous in fibroblasts from their child with PA. Another PA fibroblast line possessed mutations in both genes, ultimately determined as compound heterozygous PCCA and monoallelic PCCB. In total, out of 14 unique disease-associated variants, 10 mutations were located within exons and four mutations led to splicing variants. A comprehensive search of dbSNP, ClinVar and PubMed databases suggested that our analysis identified four unreported PCCA genetic variants, and one unreported PCCB genetic variant associated with PA. This information will be helpful for researchers and clinicians diagnosing patients with PA, utilizing these PA fibroblasts, and developing therapeutics for PA. Furthermore, our experimental approach could be adapted to characterize other diseases with complex underlying genetic mutations.

973 Evaluation of the Immunoregulatory Effects of Mesenchymal Stem Cell Derived Extracellular Vesicles

Nikolia Darzenta

Pathobiology, Auburn University, Auburn, AL

Introduction. Novel investigations in regenerative research highlight the in vivo and in vitro immunoregulatory properties of Mesenchymal

Stem Cell's secretome attributed to Extracellular Vesicles (MSCs-EVs). EVs is a heterogenous population of cell - free double layer membrane - bound carriers enriched with parental cell-derived active cargos that contribute to the intracellular communication through the delivery of signal molecules. More specifically, stem cell derived EVs have been proved to alleviate neuroinflammation and neurodegeneration via suppression of astrogliosis and microgliosis. In addition, they can also cross the brain - blood barrier, making them a promising tool to fight the CNS pathology. Sandhoff disease (SD) is a GM2 Lysosomal storage disease (LSD), caused by specific mutations of the N-acetyl-β-hexosaminidase (Hex), that causes progressive, rapid and fatal neurodegeneration in children by the age of 5. Moreover, this genetic disease is characterized by inflammatory features that are typical of all neurodegenerative diseases such as astrogliosis and microgliosis. Therefore, using a well characterized single gene disorder will allows us to demonstrate the anti-inflammatory effects of MSC-EVs on immune cells that are mainly involved in neuroinflammation before proceeding to in vivo experiments. Our objective was to evaluate the immunosuppressive properties of MSCs-EVs on astrocytes and, microglia in the feline in vitro SD model and compare to those normal cats. **Methods**. Brain tissue and whole blood from cats with SD and normal cats was used to isolate astrocytes and, microglia. Phenotypic characterization was performed via flow cytometry and immunofluorescence while 10^8 isolated from serum free conditions and characterized umbilical cord derived hMSCs - EVs were added to naïve and LPS-stimulated cells in order to assess their immunoregulatory effect. Cell culture supernatants were collected and analyzed for the production of pro-inflammatory cytokines, such as IL-6, through ELISA while mRNA expression of pro- inflammatory cytokine was assessed via reverse transcriptase quantitative PCR. **Results**. Isolated microglia and astrocytes from feline brain express cell specific markers, such as CD11b/c, CD18 and GFAP, accordingly. Also, our preliminary data indicate an immunomodulatory effect of hMSCs - EVs, through alteration in the mRNA expression of the pro - inflammatory cytokines in naïve and stimulated microglia and, astrocytes isolated from SD cats. Conclusions. These findings provide novel insights on how the hMSCs -EVs can be a promising tool against neuroinflammation in the SD feline in vitro model and their potential use in translational studies to fight diseases that are characterized by neurodegeneration, and neuroinflammation. **Acknowledgements**. 974 New Technologies for CAR-T Characterization and Potency Testing

Julia Gilden, Pete Stecha, Aileen Paguio, Alex Steil, Jim Hartnett, Jeff Nelson, Iain Ronald, Brock Binkowski, Frank Fan, Mei Cong

Promega Corporation, Madison, WI

Despite significant clinical advances in CAR-T cell therapies for cancer, the ability to precisely and reproducibly analyze the potency and identity of these drug products remains a challenge. As new CAR-T products and production methodologies are developed, it is becoming increasingly important to be able to rigorously evaluate the relative potencies of each batch. We have developed two MOA-based bioluminescent assays that overcome challenges in quantitative assessment of T cell therapies. Both assays rely on split NanoBiT luciferase technology. In the HiBiT Target Cell Killing Assay, incubation of CAR-T cells with target cells stably expressing HiBiT results in lysis of the target cells and release of HiBiT proteins. These HiBiT proteins bind with high affinity to LgBiT in the detection reagent and form functional NanoBiT luciferase, resulting in production of light in proportion to target cell lysis. Lumit Immunoassays are a simple and homogeneous method for measuring cytokine production from engineered T cells. Monoclonal antibodies are covalently labeled with LgBiT and a low-affinity tag, SmBiT, which have negligible association in solution. When the antibodies are brought together on a common analyte, such as a cytokine, SmBiT and LgBiT can compliment to form NanoBiT luciferase and produce light in proportion to the concentration of analyte in the sample. Lumit Immunoassays can be run directly on cells, removing media transfer, dilution, and wash steps that can be common sources of error. When autologous CAR-T products are being produced in parallel, it is essential to verify the identity of each product and ensure that it is administered to the correct patient. We demonstrate an easy workflow for STR analysis that can be used to document the chain of identity for CAR-T products.

975 The Unexpected Dual Impact of a Specific Transfection Reagent on the Biology of AAV

Oded Singer

Life Sciences Core Facilities, The Weizmann Institute of Science, Rehovot, Israel

AAV production - According to textbook, production of rAAV, without a helper virus, require nuclear extraction of packaging cells in order to release virions from cells. Nevertheless, many published protocols include a medium extraction step in addition to cellular extraction step. We have discovered that the use of the common transfection reagent - PEI specifically, to produce rAAV, resulted with substantial amount of virus released in the medium of packaging cells. **Methods:** HEK293T were transfected with packaging plasmids for production of AAV-GFP-DJ using PEI method at ratio of 1:2 or 1:3 (DNA to PEI) or using $CaPO_4$ method. Media was changed at 18 hrs post transfection; media from producing cells was collected by filtration (72 hrs post transfection) and AAV-GFP infectivity was estimated by serial dilutions (**Fig. 1A**). In addition, rAAV was extracted from cell pellet and viral genome (vg) copies were measured by qPCR (**Fig. 1B**). The amount of cellular rAAV is comparable with all transfection methods however a clear increase of virus in media collections is noticed with PEI transfections, especially when a ratio of 1:3 is used (x20 over $CaPO_4$). This phenomena was observed with all tested serotypes including, AAV1, 2, 5, 6, 8, 9 and many other recombinant capsids such as DJ, AAV-retro and Php.S. PEI induced rAAV secretion was not dependent on transfection itself and could be recapitulated by adding free PEI, without DNA, to medium of transfected cells (non PEI reagents), 24 hrs post transfection (data not shown). Interestingly, PEI induced rAAV secretion was not observed in suspension packaging cells but was regained upon adaptation of suspension cells to adherent growth in serum containing media (data not shown). **AAV infectivity** - Surprisingly, PEI has an additional inhibitory effect on rAAV infectivity however this effect was found to be serotype dependent and thus far is limited to heparan sulfate proteoglycan (HSPG) binding serotypes such as AAV2 and DJ but not AAV1 (**Fig.**

2). PEI inhibition was almost exclusively dependent on the addition of PEI to culture medium prior to virus inoculation. Incubation of heparin agarose with PEI prior to AAV2 binding and column purification had no impact on virus recovery from the column (data not shown). This preclude the possibility that PEI interfere directly with ligand binding of AAV2 but open up a compelling scenario where free PEI have an inhibitory effect on post ligand binding pathway of HSPG binding serotypes. This may hint that alternative internalization routes exist for AAV1 and AAV2 (and potentially other serotypes), and that the choice of route is directly linked with serotype specific ligand binding. Collectively, preliminary data suggest that linear polyethylenimine (**PEI**), commonly used as a transfection reagent for production of rAAV and other viral vectors have an unusual dual effect on AAV biology.

Fig. 1 Effect of PEI transfection on AAV-GFP secretion during production.

976 Development of an Intravitreal (IVT) Gene Therapy for Geographic Atrophy (GA) by Overexpressing Complement Factor I (CFI) to Inhibit the Complement Cascade

Gustavo de Alencastro, Jie Ma, Anna Zaslavsky, Stephanie Lussier, Kelly Michiko Hanna, Kellie Schaefer-Swale, Alex Tai, Charu Kumar, Cameron K. Baker, Ali Aghajanirefah, Ruslan N. Grishanin, Brigit E. Riley

Adverum Biotechnologies, Redwood City, CA

Dry age-related macular degeneration (Dry AMD) with geographic atrophy (GA) is a highly prevalent disease, characterized by retinal pigment epithelium (RPE) and photoreceptor death leading to vision loss, which affects the quality of life in the aging population worldwide. Although the cause of Dry AMD is unknown, activation of components of the complement cascade have been associated with GA. More recently, data from clinical trials support that inhibition of the complement cascade can reduce GA lesion growth. Complement Factor I (CFI) is a rate-limiting enzyme in the complement cascade, naturally inhibiting the activity of proteins involved in complement overactivation. Therefore, continuous overexpression of CFI in the ocular tissue has the potential to inhibit the complement cascade in the eye, halt GA lesion growth and preserve vision in patients with Dry AMD. This can potentially be achieved by intravitreal (IVT)-delivery of adeno-associated viral (AAV) vectors engineered for broad retinal transduction and CFI expression. The ability to administer AAV vectors to patients via IVT delivery, a routine in-office procedure, is ideal for highly prevalent ocular disorders such as Dry AMD. In order to generate an AAV vector to treat patients with GA, we developed an improved codon-optimized CFI human cDNA (CFIco) sequence, which improved CFI expression over the wild-type sequence. This CFIco sequence was cloned into an AAV backbone under the transcriptional control of strong regulatory elements (named AAV-CFIco). Next, to evaluate the best AAV serotype for IVT delivery, AAV-CFIco was packaged into two of Adverum's proprietary highly retinotropic serotypes - AAV2.7m8 and AAV2.5T-LSV1 - which have shown to successfully transduce retinal cells following IVT delivery. After transduction of ARPE19 and rabbit retinal explants, both AAVs produced functional CFI protein in the culture media. To assess whether AAV2.7m8-CFIco and AAV2.5T-LSV1-CFIco could generate ocular CFI in a model system similar to humans, we performed a study using non-human primates (NHP). In this study, NHP subjects were administered bilateral IVT injections of AAV2.7m8-CFIco or AAV2.5T-LSV1-CFIco at either 3E10 vector genomes/eye (vg/eye) or 1E11 vg/eye (n=3/group), or vehicle (n=3/group). Vitreous humor (VH) was collected for CFI quantification on days 28, 62 and 88 post dose. Administration of AAV2.7m8-CFIco and AAV2.5T-LSV1-CFIco at both doses resulted in production of CFI. Mean peak CFI levels at the 3E10 vg/eye dose were 2464 ng/mL for AAV2.7m8-CFIco and 575 ng/mL for AAV2.5T-LSV1-CFIco. At the 1E11 vg/eye dose, mean peak CFI levels were 2313 ng/mL for AAV2.7m8-CFIco and 557 ng/mL for AAV2.5T-LSV1-CFIco. Overall, IVT administration of AAV2.7m8-CFIco and AAV2.5T-LSV1-CFIco in NHP subjects was well tolerated. No adverse systemic clinical signs were observed during the 3-month study. Animals had dose-dependent and self-resolving slight to mild ocular inflammation characterized by pigment and cells in the vitreous, and no abnormalities of the anterior segment or lens were found. In summary, the findings from the NHP study suggest IVT administration of either AAV2.7m8-CFIco or AAV2.5T-LSV1-CFIco at doses as low as 3E10 vg/eye (human equivalent dose of 6E10 vg/eye) may be capable of providing sustained therapeutic levels of CFI for the treatment of Dry AMD patients with GA. Importantly, the IVT route of administration allows for the routine in-office administration, something critical for this highly prevalent disease.

977 Gene Editing in the Lung Using Polymeric Vehicles

Alexandra S. Piotrowski-Daspit[1], Alexandra Suberi[2], Laura G. Bracaglia[3], Laiba Akhtar[2], Madalina Ene[2], Hee Won Suh[2], Peter M. Glazer[4], W. Mark Saltzman[2]

[1]Biomedical Engineering, University of Michigan, Ann Arbor, MI,[2]Biomedical Engineering, Yale University, New Haven, CT,[3]Chemical and Biological Engineering, Villanova University, Villanova, PA,[4]Yale University School of Medicine, New Haven, CT

The lungs remain a key organ of interest for the treatment of myriad diseases, such as cystic fibrosis, with gene therapy and gene editing therapeutics. Non-viral lipid- and polymer-based vehicles have shown promise for nucleic acid delivery *in vitro* and *in vivo*. However, the primary barrier for clinical translation remains delivery to target tissues *in vivo*. Local deposition throughout the airway can be achieved through inhalation and facilitates targeting of the epithelium. Inhaled mRNA delivery has been achieved through a variety of administration routes, including: intranasal, oropharyngeal, nebulization chamber, and intratracheal (IT) delivery. We have utilized IT administration to deliver both Cre mRNA (1) as well as CRISPR/Cas9-based gene editing agents using polymeric vehicles in the Ai14 reporter mouse model. We demonstrate that nucleic acid-based therapeutics can be effectively delivered *in vivo* using a class of polymeric vehicles consisting of members from a family of mildly cationic poly(amine-co-ester) (PACE) biodegradable polymers (2,3) that are designed for gene delivery and result in robust encapsulation of mRNA and sgRNA. Our initial studies focused on Cre mRNA delivery by PACE polyplexes via IT administration in the Ai14 mouse model. By flow cytometry, IT delivery of Cre mRNA results in ~10% tdTomato expression in bulk lung and ~30% expression in cells from bronchoalveolar lavage fluid (BALF) of treated animals. We further assessed which specific cell types in the lung were transfected: CD31+ endothelial cells, EpCAM+ epithelial cells, and CD45+ leukocytes. We observed ~20% of epithelial cells and leukocytes expressing tdTomato, with no detectable expression in endothelial cells. We next assessed the ability of PACE polyplexes to deliver SpCas9 mRNA and sgRNA to edit Ai14 mice. We measured tdTomato expression levels in the lung by flow cytometry 3 or 7 days after delivering one dose of gene editing PACE NPs. At day 3 post-treatment, the highest editing levels were observed in epithelial cells, though with less than 1% of cells exhibiting tdTomato expression by flow cytometry. Editing levels were significantly boosted when lungs were evaluated at day 7 post-dosing. In this case, we observed in ~0.5% of bulk lung cells, ~1.5% of leukocytes, and ~3% of epithelial cells, again by flow cytometry. We also imaged frozen lung sections and performed quantitative microscopy analysis of treated tissues. In this case, we quantified editing in small airways positive for tdTomato, by thresholding this signal based on the background signal from untreated control lung images. We then quantified the number of edited cells as a percentage of total cells in the airway. Using this analysis method, we observed ~60% editing in small airways on average. This number was similar among different lung samples analyzed from distinct animals. To obtain a broad sense of editing across a larger area closer to the size of a lobe, we tiled images of untreated control lungs as well as lungs from animals treated with IT-administered PACE NPs encapsulating Cas9 mRNA and sgRNA. We observe broad distribution/diffuse signal of tdTomato signal across the lung. On the whole, our findings demonstrate the promise of nucleic acid delivery mediated by inhalable polymeric carriers for the treatment of genetic lung disorders. **References** (1) Suberi A, et al. *bioRxiv*. 2022. 978 Development of a Compact RNA Base Editor by Fusing ADAR with Engineered EcCas6e

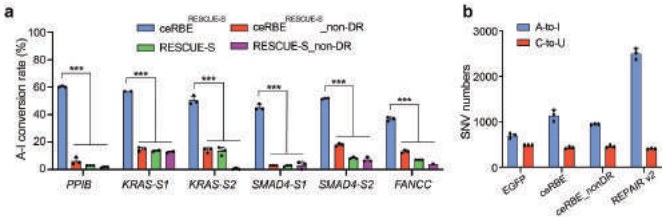
Xing Wang[1], Renxia Zhang[2], Dong Yang[1,2], Guoling Li[1], Zhanqing Fan[1], Hongting Du[1], Zikang Wang[1], Yuanhua Liu[2], Jiajia Lin[3], Xiaoqing Wu[1], Linyu Shi[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China,[3]Department of Neurology, First Affiliated Hospital, Fujian Medical University, Fuzhou, China

Background: Compared with genome editing, RNA editing is reversible and tunable without causing permanent changes in the genome, and it also has certain advantages in therapeutic applications. Among the numerous RNA base editing technologies, the base editor comprising a catalytically inactive RNA-targeting CRISPR-Cas13 (dCas13) protein and an RNA deaminase has great advantages in efficiency and editing types. This strategy has achieved efficient adenine-to-inosine (A-to-I) or cytidine-to-uridine (C-to-U) base editing *in vitro*. However, there are few *in vivo* studies due to its large size and inefficiency *in vivo*. Adeno-associated viruses (AAVs) are the most promising choice due to low immunogenicity and toxicity for *in vivo* delivery. However, the size of most base editors, consisting of dCas13 fused to an RNA deaminase, makes it difficult to package into a single AAV for efficient delivery. Here, we describe a smaller RNA base editor, ceRBE, with high efficiency *in vivo*. **Methods**: We selected ten small proteins, which belong to the CRISPR Class 1 system that recognize specific DR sequences and perform pre-crRNA processing to replace the dCas13 protein in the existing RNA base editor and explored base-editing efficiency *in vitro*. Then, the 199-amino acid EcCas6e protein was selected to optimize for toxicity and editing efficiency. Saturation mutation targeting H (His) 20 residue, a key site for pre-crRNA processing of EcCas6e protein, was performed to reduce toxicity. To improve efficiency, we optimized the editor with EcCas6e protein in three aspects: crRNA structure, subcellular localization, and spacer length. **Results**: By replacing the existing dCas13 protein with ten small proteins, we successfully achieved RNA base editing in HEK293T cells. The toxicity of the selected 199-amino acid EcCas6e protein with low off-target and high editing efficiency was reduced by saturation mutation targeting H (His) 20 residue, and editing efficiency was increased to approximately 1.3-1.8-fold by optimizing the crRNA structure, subcellular localization, and spacer length. Thereafter, the optimized **c**ompact and **e**fficient **R**NA **B**ase **E**ditor, consisting of EcCas6e^{H20L} protein, dual DR, one HIV Rev nuclear export sequence, and a 50 nt-length gRNA, is referred to **ceRBE**. Compared with the RESCUE-S editor with the same deaminase, the ceRBE editor shows a higher A-to-I and C-to-U editing ratio (A-to-I, 36.7~60.3%; C-to-U, 35.7~54.3%, Fig. 1a) and lower transcriptome off-target in HEK293T cells (Fig. 1b). To determine therapeutic potential, we packaged the editor into a single AAV and explored *in vivo* treatment of the *DMD*

Q1392X mutation in the humanized mouse model of DMD. The Q1392X (c.4174C>T) mutation results in the loss of dystrophin fibers in multiple muscle tissues. After 3 weeks of intramuscular injection of AAV, the proportion of dystrophin fibers was recovered from none to 68.1±9.4%, showing a good therapeutic effect. **Conclusions**: Overall, ceRBE, as a small and efficient RNA base editor, exhibits strong therapeutic potential for the genetic diseases.



979 Implications of AAV Affinity Column Reuse and Vector Stability on Product Quality Attributes

Harshal Soni[1], Ira Lako[2], Matteo P. Placidi[2], Steven Cramer[1]

[1]Chemical and Biological Engineering, Center for Biotechnology and Interdisciplinary Studies, Rensselaer Polytechnic Institute, Troy, NY,[2]Voyager Therapeutics, Cambridge, MA

While affinity chromatography is most preferred in the downstream processing of AAV vector products, the reuse of the AAV affinity columns is often avoided in the cGMP facility due to concerns over product quality inconsistency. Limiting the reuse of these expensive affinity columns is economically unfeasible. In this work, we examine the implications of AAV affinity column reuse and vector stability due to varying capsid design on the AAV9 product quality. An in-house pH gradient elution chromatography process with optimized clean-in-place (CIP) was developed to assess the reusability of the commercially available POROS CaptureSelect (PCS) AAVX and AAV9 affinity columns on AAV9 model vectors with varying viral protein (VP) ratios. Experiments with the drug substance AAV9 model vector feed indicated consistent vector elution behavior, independent of the vector VP ratio or column reuse cycle number. In contrast, the presence of feed impurities in the clarified lysate resulted in significantly different elution patterns during the affinity column reuse experiments. Analyzing the affinity eluates using a combination of analytical tools revealed that the product quality due to aggregation decreased over column reuse. Additionally, AAV9 serotype-specific PCS AAV9 column, with lower vector elution pH, resulted in higher aggregate content in the eluates as compared to the serotype-independent PCS AAVX column. Furthermore, the aggregation profiles also differed depending upon the model vector type with varying VP ratio. Interestingly, the vector aggregates also contained dsDNA and histone impurities. The levels of these impurities corroborated with the aggregation trends observed in these experiments. This indicates that the host cell impurities are likely carried over to the subsequent runs from column reuse due to inefficient CIP. These results suggest that the initial feed quality, affinity ligand type, elution pH, column CIP and vector stability can impact the reusability of AAV affinity columns and the product quality. This information can facilitate the rational design of a reusable AAV capture process with improved process economy and vector product quality.

980 SMART Transduction: A Framework to Control *Ex Vivo* Gene Transfer for Consistent, High Quality Cell Manufacturing

Reginald Tran[1,2], Gabriela Denning[3], Mandy Zhu[1,2], Hyoann Choi[1,2], Emily Sullivan[1], Gregory Damhorst[1], Sunil S. Raikar[1], Christopher Doering[1], H. Trent Spencer[1], Wilbur A. Lam[1,2]

[1]Emory University School of Medicine, Atlanta, GA,[2]Wallace H. Coulter Department of Biomedical Engineering, Georgia Institute of Technology, Atlanta, GA,[3]Expression Therapeutics, LLC, Tucker, GA

Transducing cells with a viral vector is the critical step that transforms a patient's cells into a living drug by restoring or conferring new functions toward curative potential. Starting material variability and interdependent transduction parameters make process control and interpretation of outcomes challenging, which has far-reaching effects on safety, efficacy, durability, and cost. The current fixed manufacturing approaches using saturating viral vector dosages, extended ex vivo culture times, or both, prioritize generating large numbers of gene-modified cells without comprehensive consideration of cell quality. Here we present screening methodologies for achieving reproducible and targeted (SMART) transduction, a combined technological platform and analytical framework to efficiently design fit-for-purpose transduction. We leverage scalable high-efficiency transductions combined with statistical models to generate case-specific fundamental insights into optimal gene transfer and preservation of downstream critical quality attributes. SMART transduction uses a personalized data-driven approach for predictive capabilities of transduction outcomes, yielding more consistent high quality cell manufacturing processes that inherently minimize viral vector usage while remaining broadly applicable to many cell therapies such as CAR-T and CD34+ HSC gene therapy.

981 Technology Evaluation: Quicker Method for Lentiviral Vector Physical Titer Determination

Saikat Chakraborty[1], Andrew Greenwald[1], Pratima Cherukuri[2]

[1]Analytical Development, Genezen, Indianapolis, IN,[2]Genezen, Indianapolis, IN

Measuring the HIV-1 p24 antigen is a long-established method for lentivrus quantitation. ELISAs can be laborious process that has numerous hands-on steps, and hours of incubation times. At Genezen, we were looking a way to decrease the time spent on physical titer determination. We evaluated ELLA instrument from Bio-Techne and VideoDrop as an alternative options to our regular p24 ELISA. ELLA uses a cartridge based system with capture antibodies and a then a fluorescent label that binds to your target, the ELLA based method streamlined and automated the immunoassay. The VideoDrop measures particles and gives a concentration of particles per mL. Initial method evaluation was performed by running Lentiviral vectors obtained from our internally developed process on the Genezen's regular ELISA assay and comparing that to the ELLA system's HIV-1 Gag protein kit. Correlation Coefficient was determined to be r=0.97 between the two methods. This is a strong positive linear correlation. Knowing that each kit could/would have different antibodies in their

assay, evaluating the trends between the samples seemed a more reasonable evaluation. Inter-analyst precision was performed. Out of 10 samples tested at 5 dilutions, there were 4 sample dilutions that had CV's between 20 and 26%. Other 46 sample dilutions were below 20% CV. Sample were also diluted across the standard curve and were found to give acceptable results out of 5 of the 6 dilutions for these samples. While the Viral Particle/mL compared between two methods, the ELLA had a Correlation Coefficient of r= 0.97 with the current Genezen ELISA method. ELLA's physical titer method was compared to the Genezen established ddPCR based Infectious titer method, and the Correlation Coefficient was 0.986. Same samples were tested on VideoDrop from Myriade. Lentivirus size ranges between 80-100nm. VideoDrop measures particles from 80 nm to 500 nm in size. In less than 1 minute the VideoDrop can analyze 7 uL of sample and produce a concentration values in Particles/mL. When compared Genezen ELISA data with he VideoDrop data, Correlation Coefficient was 0.94, which is considered a strong positive linear correlation. The VideoDrop based method could be used as a real-time in process check for Upstream and Downstream processing to reduce the time and costs.

982 Combining TRAIL-Secreting Induced Neural Stem Cell Therapy with a Novel Sensitizing Drug, TR-107 in Glioblastoma

Morrent Thang[1], Clara Mellows[2], Lauren Kass[2], Sabrina Daglish[3], Alain Valdivia[2], Lee Graves[3], Shawn Hingtgen[2]

[1]Neuroscience Center, UNC-Chapel Hill, Chapel Hill, NC,[2]Division of Pharmacoengineering and Molecular Pharmaceutics, UNC-Chapel Hill, Chapel Hill, NC,[3]Pharmacology, UNC-Chapel Hill, Chapel Hill, NC

Glioblastoma (GBM) is an aggressive malignant adult brain tumor and is characterized by poor prognosis and survival outcome. Effective therapies are urgently needed as the infiltrative and heterogeneous natures of GBM render standard-of-care treatments futile—resulting in 90-100% tumor recurrence. Pro-apoptotic protein, tumor necrosis factor related apoptosis-inducing ligand (TRAIL) is an ideal anti-cancer agent due to selectively killing cancer cells via death receptors 4 and 5 with negligible toxicity in normal cells. However, short half-life, insufficient drug accumulation at the tumor region, and development of drug resistance are critical challenges to overcome in TRAIL-based therapies against several cancers. Hence, our hypothesis is to target and activate crosstalk pathways in TRAIL-mediated extrinsic apoptosis for effective tumor suppression in GBM. Herein, we harnessed the tumor-homing capability of our human induced neural spheroidal stem cells (hiNeuroS) and engineered them to constitutively secrete and prolong TRAIL bioavailability at the tumor site. Furthermore, we combined hiNeuroS-TRAIL therapy with a novel drug, TR-107 to target crosstalk pathways for potential synergistic tumoricidal effects and to mitigate from establishing TRAIL resistance in GBM. *In vitro*, the combination therapy resulted in synergistic tumor killing effects with coefficient drug interaction values of **0.67** and **0.60** in LN229 and MS21 GBM cell lines, respectively. *In vivo*, combining a single intratumoral injection of hiNeuroS-TRAIL with intermittent intraperitoneal injections of TR-107 resulted in significant reduction of tumor growths and extended survival outcome compared to control and single agent treated groups in GBM tumor bearing mice.

983 Retroviral Replicating Vector-Mediated Prodrug-Activator Gene Therapy for Canine Cancers

Emiko Sonoda[1], Shunsuke Noguchi[2], Noriyuki Kasahara[3], Shuji Kubo[1]

[1]Laboratory of Molecular and Genetic Therapeutics, Institute for Advanced Medical Sciences, Hyogo Medical University, Nishinomiya, Japan,[2]Laboratory of Veterinary Radiology, Graduate School of Veterinary Science, Osaka Metropolitan University, Izumisano, Japan,[3]University of California, San Francisco, San Francisco, CA

Retroviral replication vectors (RRVs) can selectively infect cancer cells and continue to spread efficiently within the tumor. Although not normally cytolytic, RRV can be engineered to directly kill cells by expression of a prodrug-activator enzyme that catalyzes intracellular production of a toxic metabolite from a nontoxic prodrug. RRV have been shown to achieve therapeutic benefit in a wide variety of human cancer models, but few studies have focused on veterinary malignancies. Here, we evaluated two different types of RRV, amphotropic murine leukemia virus (AMLV) and gibbon ape leukemia virus (GALV) respectively, in experimental models of canine cancer.Both types of RRV were engineered to express GFP as a reporter gene, and replication was evaluated in 10 different canine cancer cell lines. Both AMLV- and GALV-based RRV achieved over 90% transduction by Day 30 in all these cell lines, but neither RRV replicated in canine primary normal fibroblasts and hepatocytes. Additionally, *in vivo* fluorescence imaging revealed that both types of RRV could spread efficiently through subcutaneous canine xenograft tumors (fibrosarcoma, hepatoma and lung cancer) in nude mice. Next, both types of RRV encoding the yeast cytosine deaminase prodrug-activator gene, which converts the prodrug 5-fluorocytosine to the active drug 5-fluorouracil, showed efficient killing of all 10 canine cancer cells in vitro in a prodrug dose-dependent manner. Furthermore, RRV-mediated prodrug-activator gene therapy achieved significant inhibition of subcutaneous fibrosarcoma tumor growth in nude mice.These data indicate that RRVs can be effective in the treatment of canine malignancies, and have potential applications in the veterinary field.

984 Characterization of the *Mottled-Blotch*y Mouse Model of Abnormal Copper Transport

Lalitha Venkataraman, Benjamin Kennedy, Tarun Kaniganti, Stephen G. Kaler

Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH

Menkes disease is a X-linked recessive severe neurogenetic disorder of copper metabolism characterized due to variants in the *Atp7a* copper transporter gene. A milder neurologic version of Menkes disease is modeled by the *mottled-blotchy* mouse (*mo-blo)* whose phenotype and genotype resemble human Occipital Horn Syndrome, first delineated nearly 30 years ago (*Nature Genetics*, 1994). The *blotchy* mouse phenotype is caused by an *Atp7a* "leaky" (non-canonical) splice junction variant that reduces but does not eliminate proper *Atp7a* splicing. Little is known about the quantity of correctly spliced Atp7a in *mo-blotchy*, a question relevant to viral gene therapy treatment approaches of these copper transport disorders. We sought to quantify the amount of properly spliced Atp7a transcript in *mo-blotchy* mice in order to better understand its phenotype and response to AAV9-

mediated gene replacement in combination with subcutaneous copper histidinate (CuHis). We documented *Atp7a* exon 11 skipping by RT-PCR analyses of *mo-blo* cDNA prepared from mouse brain, lung, liver, kidney and fibroblasts in comparison to normal tissues, as well as approximately 7% normally spliced *Atp7a* transcripts, based on quantitative RT-PCR relative to wild type. In conjunction with this molecular characterization, we evaluated dose responses to viral gene therapy in *mo-blo*. We identified one female pup with skewed X-inactivation The optimal dose regimen to date employs 7.6 x 10^{12} or 2.6 x 10^{13} vg/kg body weight of AAV9-*corsATP7A* in combination with 5mg of subcutaneous CuHis on P4, 5, and 6 which has resulted in 90% long term survival (n=10). We also identified one female pup with skewed X-inactivation leading to a severe phenotype and premature death. Cultured fibroblasts obtained from this mouse are under investigation for gene therapy mediated modulation of X-inactivation. The results from this study advance understanding of clinical and biochemical aspects of abnormal human copper transport and provide insight and direction for rational treatment approaches to Menkes disease and its milder variants.

985 OutSmart™ IL-2/15: A CAR T Cell-Produced Designed Cytokine with Tumor-Localized Immune Cell Activity

Brian Weitzner, Howell Moffett, Thaddeus Davenport, Leah Tait, Laura Baker, John Crowl, Willimark Obenza, Bob Bader, Bradley Hammerson, Robin Kirkpatrick, Paul Sample, Robert Langan, Andrew Ng, Scott Boyken, Aaron Foster, Marc Lajoie

Outpace Bio, Seattle, WA

Introduction: Chimeric antigen receptor (CAR) T cells are effective medicines against B cell malignancies, but CAR T efficacy for the treatment of solid tumors is impaired by insufficient CAR T proliferation and survival, and a lack of immune effector stimulation within the tumor microenvironment (TME). IL-2 is a potent T cell growth molecule that has been used as a protein therapeutic to encourage tumor-specific T cell proliferation. However, IL-2-related toxicity and T regulatory (Treg) cell stimulation limits clinical impact. We computationally designed OutSmart™ IL-2/15 lacking IL-2Rα binding to limit Treg activation and minimize toxicity, while retaining IL-2/15Rβγ binding interfaces and incorporating antigen-targeting to preferentially stimulate specific cell types such as CD8+ T cells and NK cells. We implemented OutSmart™ IL-2/15 as an integrated component of the genetic construct encoding the CAR, using novel promoters to regulate cytokine production at the tumor. Combining these design elements into a single vector module enables context-dependent, local delivery of the cytokine to the TME to enhance CAR T cell function, promote bystander immune cell function, and reduce the risk of toxicity. **Results:** Wild-type (WT) IL-2 was redesigned to replace IL-2Rα binding regions with short structured loops that increased protein stability and ablated interaction with IL-2Rα; the remodeled backbone results in a novel α-helix connectivity while retaining the WT IL-2Rβ and IL-2Rγ interfaces. 10,355 designs were generated, of which 38 were prioritized based on in silico analysis. 38/38 (100%) designs ablated IL-2Rα binding, and 33/38 (87%) designs retained IL-2/15Rβγ signaling. Designs were further optimized and prioritized based on biophysical characterization, phospho-STAT5 (pSTAT5) activation, and in vitro proliferation assays. Comparisons of pSTAT5 activation of CD8+ T cells, NK cells, and Tregs showed that WT IL-2 preferentially activated Tregs, whereas OutSmart™ IL-2/15 reduced Treg activity by 3-logs with minimal reduction in potency for CD8+ T cells and NK cells. T cells genetically modified with lentiviral vectors encoding WT IL-2 or OutSmart™ IL-2/15 showed that secretion was sufficient to drive T cell expansion in vitro. To enable context-dependent cytokine production from the CAR T cells, promoter/enhancer elements that respond to CD3ζ signaling were evaluated for low baseline activity and CAR-responsiveness following antigen engagement. We prioritized two "stim-on" promoters that demonstrated increased cytokine production following CAR activation by immobilized target antigen. OutSmart™ IL-2/15 production in response to CAR stimulation improved CAR T-mediated tumor killing and proliferation in repetitive tumor challenge studies. **Conclusions:** We demonstrate a genetic module that enhances CAR T cell function via tumor-localized IL-2/15 activity. OutSmart™ IL-2/15 preferentially expands anti-tumor immune effector cells, including NK cells and CD8+ T cells, while minimizing Treg activation via ablation of IL-2Rα binding. Our "stim-on" circuits leverage novel promoters to achieve local secretion of OutSmart™ IL-2/15 to enhance CAR T proliferation and survival, stimulate immune effector cells in the TME, and reduce potential side effects associated with systemic IL-2 exposure. Antigen targeting provides additional control by retaining the cytokine near the tumor and biasing activity to specific cell populations. More generally, OutSmart™ protein design pipelines and control technologies can be applied to create other designed cytokines, creating a powerful platform to achieve tumor-localized cytokine activity.

986 Spearheading Change from Scientist to Patients: The AI Impact on Cell & Gene

Claire Aldridge[1], Adam Cockrell[2]

[1]Form Bio, Austin, TX,[2]Solid Bio, Cambridge, MA

It is projected that cell and gene therapies represent a $58 billion market opportunity over the next 5 years and hold the potential to treat millions of people with life-threatening diseases. While the cell and gene therapy space is a new frontier, the industry's focus should be on therapy development to scale and meet the substantial market for these novel therapeutics. More than just research and development, there is a growing need to focus on manufacturing process improvements that can overcome critical design issues and inefficiency that cost millions in wasted costs, elevated risk of adverse immune responses, and prohibitively high costs per dose. In recent years, AI technology has improved many industrial inefficiencies and can enable drastic design process improvements for cell and gene therapy pipelines. Digital tools are the next layer that can unlock operational challenges in production - through yield optimization with advanced analytics-based models, giving manufacturers proactive identification before any potential scaling issues occur.AI is the critical component and the prompt of this paradigm shift. The presentation will explore considerations for using proprietary AI models that analyze gene therapy constructs and optimize their operational process. First, the investment in an advanced AI technology stack built with large language models can be applied to biology problems. Model training for hyperparameter optimization and inference performance can enable a dramatically better experience, case studies showcasing 18x faster output, 5x cost-

effectiveness, and a 350% reduction in memory usage. The analysis can then be done as a more scalable and repeatable method. Form's state-of-the-art transformer neural network architecture for large language models identifies what's important when applied to DNA and protein analysis. Training this for specific biological tasks, such as construct replication efficiency leads to improvements in full capsids. AI is then taken to the next level, using coding and inference architecture for variant effect prediction and methylation to understand more deeply how changes can impact expression. Through training machine learning models based on specific, well-established DNA features, we understand multiple variables that impact truncation propensity, allowing visibility into secondary and tertiary structures that lead to truncation. While design for manufacturing via AI models has the potential for meaningful impact, practical application is of much more value. The presentation will feature a case study detailing our partnership with a publicly traded gene therapy company and how 30 days of AI analysis of AAV-based therapy predictively increased full reads by 18% and decreased truncations by 70% - increasing manufacturing yield, improving safety, and de-risking clinical development. Failures in replication and packaging of rAAV genomes into assembled capsids cause manufacturing efficiency/yield to plunge, accounting for millions of dollars in capital and months/years of manufacturing trial and error per pipeline candidate. In further detail, the presentation will break down. Evidence of how AI models can predict different truncation propensities in multiple indications across four gene therapy constructs with the same manufacturing process, as opposed to the reactive process of leading codon tools. Our never-before-performed technique of predicting and weighting a variety of 2o and 3o structures as part of construct design and to avoid increased mutation rates and replication machinery malfunction typically following secondary and tertiary DNA structures confirmations The biologics industry hasn't realized the potential of the newest advancements in machine learning to improve novel therapeutic manufacturing. Improvements like these can increase accessibility, and safety, and drastically decrease R+D timelines - to bring more doses to market and to patients in need.

987 Rational Designed Cationic Ionizable Lipids with Unique Hyperbranched Structures Exhibited Excellent *In Vivo* Nucleic Acid Delivery Efficiency

Xi Zhu, Hong Chen, Dalang Li, Chenxi Hou, Jiaming Ren, Shin-Shay Tian, Xiaoping Zhao
Shanghai Vitalgen Biopharma, Shanghai, China

Background: Lipid nanoparticles (LNPs) are currently being evaluated as a non-viral delivery system in clinical translation of *in vivo* genome editing technology. Transient expression of the gene editors of LNP/CRISPR Cas mRNA/gRNA cargo provides hit-and-run editing, which minimizes potential off-target risk to improve safety in clinical applications. Although excellent editing efficiencies have been reported in early-phase clinical trials for CRISPR-based therapeutics delivered by LNP, those were achieved by using very high doses (up to tens of mg) of RNA, which increases cost and tox risk. For the currently reported LNP technologies, it is estimated that less than 1~5% of the RNA payload of the endocytosed LNP escapes from endosomes into the cytosol. Therefore, there is room for improvement of the delivery efficiency by increasing the endosomolytic behavior of LNPs. Cationic ionizable lipid (CIL) is the most critical component in LNP formulation, which determines the cytosol delivery efficiency of the nucleic acid payload. CIL-mediated endosomal escape has been hypothesized to be a process associated with hexagonal II phase transition of lipid ion pairs, which might further trigger membrane fusion and disruption. However, this hypothesis has not been well-validated and rarely been applied in the discovery of new CILs. We therefore sought to develop novel CIL molecules with improved cytosol delivery efficiencies based on this hypothesis. **Methods:** Using a rational design and iterative screening strategy, a library of CIL molecules was synthesized and evaluated *in vitro* and *in vivo*. All CIL molecules synthesized have low molecule weights, with relatively simple yet hyperbranched structures. We hypothesized this unique molecular property could potentially facilitate hexagonal II phase transition. **Results:** After an extensive screening campaign in *in vitro* cell-based assays and *in vivo* studies in rodents, two lead candidates, VG-L61 and VG-L819, were identified exhibiting very high mRNA delivery efficiencies. The two novel CILs and a reference CIL, LP01, which was used in NTLA-2001 (the first *in vivo* CRISPR therapy tested in a clinical trial) were further evaluated *in vivo* using EPO mRNA as a reporter molecule. Following intravenous administration in mice, the serum EPO concentrations from VG-L61-based LNP and VG-L819-based LNP were 4.6 and 8.9 times that of LP01-based LNP, respectively. Interestingly, both VG-L61 and VG-L819 have hyperbranched structures with very short branching arms. Additionally, no increases of transaminases were observed in mice at 24 h post injection at doses up to 100 mg/kg of CILs. **Conclusions:** Using a rational designed strategy, novel CIL molecules were identified with significantly improved nucleic acid delivery efficiencies and good safety profiles. These results provided evidence for the hexagonal II phase transition theory, and also demonstrated that LNP delivery efficiency could be improved by further increasing the endosomolytic activities of the CILs. Experiments are ongoing to test these novel CILs for the *in vivo* delivery of genome editors.

988 Standardizing a Protocol for Streamlined Synthesis and Characterization of Lipid Nanoparticle to Enable Preclinical Research and Education

Shilpi Agrawal, Abbey Bryan, Christopher E. Nelson
University of Arkansas, Fayetteville, AR

Nanotechnology has made remarkable advances in clinical applications since the late 20th century. Due to the noticeable advantages in biocompatibility, drug delivery, and novel therapeutic and diagnostic applications, lipid nanoparticles (LNPs) have been used in gene therapy and vaccines. Recently, the clinical relevance was demonstrated by Pfizer and Moderna during the COVID-19 pandemic by making mRNA vaccines using LNPs. However, there are remaining challenges that impede preclinical work, such as expensive equipment and the lack of efficient delivery to non-hepatic tissue target. As more labs look to incorporate this technology, creating a standardized protocol at a relatively low cost would increase access and discovery. There are three methods that are commonly used to synthesize LNPs: pipette, vortex, and microfluidic mixing. LNP formulations generated *via* the microfluidics platform have been demonstrated to have enhanced properties for biomedical applications with increased loading efficiency

and proper size distribution. Microfluidic mixing is commonly performed using expensive equipment. For our purposes, we created a standardized protocol for microfluidic mixing using a syringe pump and an off-the-shelf microfluidic chip due to its comparatively low cost and high reproducibility. This protocol provides in-depth procedures on the synthesis of LNPs by microfluidic mixing and physical characterization using DLS (Zetasizer Nano ZS90, Malvern), nanoparticle tracking analysis (NanoSight NS300, Malvern), and evaluation of *in vitro* transfection efficiency and cytotoxicity. The protocol was created by recreating 3 well-known LNPs. Each LNP formulation contained an ionizable lipid: Cholesterol: DSPC: DMG-PEG. The ionizable lipids used were LP01, DLin-MC3-DMA, and SM102. DLin-MC3-DMA-LNP was made with a percentage ratio of 50:38.5:10:1.5, and we reported a size of 163 nm, a PDI of 0.140, a zeta potential of -5.94 mV, and an encapsulation efficiency of 99.4%. Similarly, LP01-LNP was made with a percentage ratio of 45:44:9:2, and we reported a size of 136 nm, a PDI of 0.10, a zeta potential of -12.6 mV, and an encapsulation efficiency of 94.7%. Lastly, SM102-LNP was made with a percentage ratio of 50:38.5:10:1.5, and we reported a size of 129 nm, a PDI of 0.10, a zeta potential of -36.77 mV, and an encapsulation efficiency of 94.9%. We observed successful transfection in HEK293 cells by each formulation mentioned above. In a 24-well plate, 75 ng-150 ng of GFP plasmid was added to the cells. A difference in expression was not observed for 100, 125, and 150 ng along with no observed cell death. Factors investigated to optimize manufacturing and size distribution was dialysis time, freeze-drying capabilities, reusability of microfluidic chips, and LNP stability after 30 days. We hereby report that our protocol will be used to fabricate LNPs to deliver mRNA to skeletal muscle and immune cells. To target immune cells, a new library of LNPs will be designed using the protocol to ensure the high probability of achieving an effective monodisperse sample.

989 Targeted Approach to Immunosuppression with AAV Gene Therapy: Nonclinical Support of Clinical Approaches

Tracy McGregor[1], Mijeong Kim[2], Daisy Huynh[2], Yvonne White[3], Teresa Wright[3], Rakesh Sindhi[4], Julie Jordan[3]

[1]Homology Medicines Inc., Bedford, MA,[2]Immunology, Homology Medicines Inc., Bedford, MA,[3]Homology Medicines, Bedford, MA,[4]Plexision, Pittsburgh, PA

Gene therapy using recombinant adeno-associated virus (rAAV) vectors has been successful in treating a wide range of human diseases. However, patients treated with rAAV can develop unwanted immune responses to the viral capsid, including B- & T-cell activation and transaminitis, which can lead to the loss of therapeutic transgene expression and formation of neutralizing antibodies, the latter hampering the potential for re-dosing. To combat the immune response to rAAV gene therapy and gene editing, corticosteroid usage has become more frequent over time in clinical trials, particularly with systemic AAV delivery. Given the broad mechanism of action of corticosteroids, adverse effects can be expected across a range of organ systems including hypertension, hyperglycemia, osteoporosis, and neuropsychiatric symptoms, such as insomnia and mood disturbance. Higher doses and longer courses of corticosteroids have been associated with an increased likelihood of developing more severe side effects. Because of these side effects, more targeted approaches are under investigation. In a 28-day study in cynomolgus monkeys, we investigated the effect of an immunosuppressive regimen on AAVHSC17-capsid specific nAb formation, immune activation, and transgene expression. The calcineurin inhibitor, tacrolimus (Prograf®), and the corticosteroid, dexamethasone, were administered prophylactically for immunosuppression, followed by a single intravenous (I.V.) dose of rAAVHSC17 expressing human phenylalanine hydroxylase (rAAVHSC17-PAH). The tacrolimus-and-dexamethasone immunosuppressive regimen used in this study reduced nAb formation against the rAAV capsid by 8-fold, reduced overall B- and T-cell activation, and increased transgene expression by 2-fold when compared to a control group administered rAAVHSC17-PAH without immunosuppression. The results of this study support the approach of a prophylactic combination of tacrolimus and dexamethasone in in conjunction with dosing in clinical trials of our investigational gene therapies. The pheEDIT and juMPStart trials are Phase 1 open-label, sequential, dose-escalation studies that will evaluate the safety and efficacy of a one-time I.V. administration investigational gene therapy vectors. The pheEDIT study is a geneediting vector and will be evaluated in adult participants with phenylketonuria (NCT05222178). The juMPStart study will evaluate the safety and efficacy of a one-time I.V. administration of HMI-203, an investigational gene therapy, in adult participants with Mucopolysaccharidosis Type II, also known as Hunter syndrome (NCT05238324) To decrease the potential for immune response to AAV gene therapy in these studies, a prophylactic immunosuppressive regimen of a corticosteroid in combination with tacrolimus are administered. The introduction of a T-cell inhibitor tacrolimus allows for a potential shortening of the duration of exposure to high dose corticosteroids and a more rapid taper. This combination therapy is anticipated to decrease the development of nAb, optimize transgene expression and reduce the adverse events related to corticosteroid therapy.

990 Improvement of Yield and Critical Quality Attributes through Process Development of a Novel Adeno-Associated Viral Vector Capsid (Anc80L65)

Thomas M. Edwards[1], Matt Bennett[1], Patrick Bresnahan[1], Paul Freeman[1], Mark Galbraith[2], Rupshika Rajasekaran[1], Yang Wang[1], Hongxing Wang[3]

[1]Process Science, Affinia Therapeutics, Waltham, MA,[2]Analytical Science, Affinia Therapeutics, Waltham, MA,[3]Affinia Therapeutics, Inc., Waltham, MA

Affinia Therapeutics is pioneering a new class of rationally designed gene therapies. We utilize our Affinia rationally designed Therapies (ART) platform to develop these therapies. One focus is developing novel capsids that enhance tissue targeting specificity, immunological profile, and manufacturability. One of the first capsids to come from this effort was Anc80L65 first identified by the Vandenberghe lab. In preclinical studies Anc80L65 has demonstrated rapid and broad gene expression in CNS compared to AAV9. We wanted to demonstrate that these rationally designed capsids can have similar manufacturing and stability profiles to natural serotypes. Multiple process development strategies were applied to improve total process yield and CQA's. Our platform upstream process

utilizes suspension HEK293 cells, so we started by testing different cell culture media, transfection reagents and transfection parameters utilizing Design of Experiment methodology. Through these efforts, we demonstrated over a log increase in yield at harvest in both shake flasks and bioreactors to >2e11 vg/mL. We then sought to develop a high yielding downstream purification method. We demonstrated that Anc80L65 can be purified with multiple commonly available affinity resins. We developed two polishing methods, with CsCl gradient we achieved >90% full capsids and for anion exchange chromatography we achieved >70% full capsids. We looked at other common critical quality attributes such as hcDNA, HCP, residual plasmid DNA and believe our process generates high quality vector. Stability is an important metric for AAV capsids, and we were able to show that Anc80L65 is stable at -80C for at least 12 months. Overall, we have demonstrated that Anc80L65 is a highly manufacturable capsid and gives us confidence our manufacturing platform will translate to newly discovered capsids.

991 Funding AAV Therapy for Sanfilippo Syndrome May Be More Cost Effective for Society Than Status Quo

Frederick J. Ashby[1], Coy Heldermon[2]

[1]College of Medicine, University of Florida, Gainesville, FL,[2]Department of Hematology and Oncology, University of Florida/Shands Hospital, Gainesville, FL

Rare diseases are frequently considered to be a secondary public health and research concern, yet the cumulative cost of all rare diseases have profound effects on society as a whole, and traumatic outcomes for families affected. Sanfilippo syndrome, for example, is an exceedingly rare genetic disease in the United States, has a small patient population and its research relies heavily on private donors. Sanfilippo syndrome causes profound neurological deficits, early death, and detrimental trauma to families for years, yet it's cumulative cost-burden in the United States has never been quantified. A multi-stage multiplicative comorbidity analysis was constructed using publicly available data and literature to simulate the predicted effects of Sanfilippo syndrome and its commensurate value to the public in USD based on the United States healthcare system's value of disability-adjusted-life-years (DALYs) presuming a 3% annual discount rate from 2020. The analysis demonstrated that, with the current standard of care for Sanfilippo syndrome, societal costs between 2020-2040 approximate to $1.34 billion, with the cost to individual families exceeding $8 million per child born with Sanfilippo syndrome. Societal costs approach $2.59 billion by 2100 despite a slowing birth rate in the United States, underscoring the cost of business-as-usual when funding individual rare diseases. Ultimately, this analysis supports the notion of increasing allocation of public research funds for rare diseases, such as Sanfilippo syndrome, not only from a humanitarian perspective, but also as a means of potentially reducing overall societal burden in a cost-effective manner. This analysis suggests that even allocating millions of dollars per year for Sanfilippo syndrome alone would potentially still be cost-effective compared to status quo, presuming novel treatments would be effective.

992 Assessment of Factors That Contribute to Inflammatory Toxicities During CAR-T Cell Therapy

Md Kamal Hossain, Nirjal Bhattarai

FDA, Silver Spring, MD

Inflammatory toxicities such as cytokine release syndrome (CRS) and immune effector cell-associated neurotoxicity syndrome (ICANS) are commonly associated with chimeric antigen receptor T cell (CAR-T cell) therapy. Although the mechanisms responsible for development of inflammatory toxicities are not completely understood, activation of bystander myeloid cells (MCA) and release of pro-inflammatory cytokines such as IL-6 and IL-1β following CAR-T cell therapy contribute to this. It is unclear how myeloid cells are activated during CAR-T cell therapy. GM-CSF produced by activated CAR-T cells has been suggested to activate myeloid cells; however, GM-CSF protein neutralization by antibodies or gene knock-out (KO) in T cells using CRISPR/Cas does not completely prevent MCA. This suggests that other T cell factors contribute to MCA. Fractionation studies of activated T cell supernatant identified a fraction of size range 100-300 kDa, which significantly activated myeloid cells compared to <100kDa and >300kDa fractions. Mass spectrometry analysis of 100-300kDa fraction identified several candidate proteins that may contribute to MCA. Protein function analysis and literature review identified a novel protein, GP1BA as one of the candidates. Neutralization of GP1BA in T cell supernatant using antibodies from 2 different sources significantly reduced MCA. However, GP1BA gene KO in T cells did not prevent MCA. Furthermore, recombinant GP1BA protein did not cause MCA. Interestingly, addition of anti-GP1BA antibodies in the supernatant from GP1BA KO T cells also prevented MCA. So far, these data suggest that T cell derived GP1BA does not contribute to MCA but GP1BA antibodies cross-react with an unidentified T cell-derived inflammatory factor, which contribute to MCA. Current studies are underway to identify inflammatory factor(s) that cross-react with GP1BA antibodies. Our long-term goals are to identify soluble factors released by CAR-T cells that contribute to inflammatory toxicities, and rationally engineer CAR-T cells that are safer and effective.

993 A Novel Fusogenix Proteolipid Vehicle-Based Platform for Efficient Delivery of Gene Therapy Products into the Eye

Maryam Hejazi[1], Liliya Grin[1], Ivana Marchanda[1], Bijal Rawal[1], Ping Wee[1], Prakash Bhandari[1], Jitendra Kumar[1], Paola Solis[1], Douglas Brown[1], Amir Bukhari[1], Hector Vega[1], Rodrigo Quevedo[1], fahed Elian[1], Natasha Rana[1], Brendan Todd[1], Natasha Govindasamy[1], Angela Delmage[1], Chandra McAllister[1], Arun Raturi[2], John Lewis[1]

[1]Entos Pharmaceuticals Inc, San Diego, CA,[2]Entos Pharmaceuticals, Edmonton, AB, Canada

Introduction: Common eye diseases leading to vision loss include, age-related macular degeneration, retinitis pigmentosa, diabetic retinopathy, stargardt disease, and glaucoma. Gene therapy offers a promising platform to reverse vision loss as well as treat the diseases which are untreatable today. Major barriers to the development of gene therapies for the eye include the inefficient delivery of nucleic

acids across different tissues and toxic side effects. The Fusogenix Proteo-Lipid Vehicle (PLV) technology overcomes these problems by employing the use of well tolerated lipids and the fusion-associated small transmembrane (FAST) protein, a small viral membrane protein that has evolved to induce cell-to-cell fusion and is non-immunogenic due to its small size.The goal of this study was to test whether our novel PLV can efficiently deliver nucleic acids *in vitro* in RPE cells and murine retina *in vivo*. Here, we investigated the use of our highly tolerable PLV formulations for eye tropism, by encapsulating different nucleic acids such as mRNA, pDNA, and siRNA. **Methods and Results:** PLVs encapsulating eGFP-mRNA and eGFP-DNA were first tested in *in vitro* models utilizing human RPE cell lines as well as isolated mouse retinal cells. PLVs showed high transfection efficiency with little to no cytotoxicity. Next, we tested the biodistribution of PLVs *in vivo,* using C57BL6 mice. PLVs encapsulating non-targeted luciferase-DNA (luc-DNA) were delivered via intravitreal injection. The *in vivo* and *ex vivo* imaging revealed expression of luc-DNA in the retinal layer and lens. Furthermore, immunofluorescence analysis revealed the co-localization of luciferase with different cell type-specific markers, specifically, tuj1 and rhodopsin, indicating a stable expression of DNA in retinal ganglion cells and photoreceptor cells. Furthermore, we tested PLVs encapsulating siRNA for functional protein KD following intravitreal administration, and observed ~70% knockdown. Finally, we tested the off-target effects of PLVs compared to commercial MC3-LNP formulations following intravitreal administration of mRNA-Luc. A strong luciferase expression was detected in the liver of MC3-LNPs, whereas PLVs did not show any luciferase signal. **Conclusion:** Our results indicate that Fusogenix PLVs can be used to effectively and safely deliver mRNA, pDNA, and siRNA *in vitro* and *in vivo*, with broad biodistribution in the murine eye, and unlike conventional LNPs, has no off-target effects. We demonstrate that Fusogenix-PLV offers a promising gene delivery platform for eye therapeutics.

994 Comprehensive Analysis of the AAV9 Galactose-Binding Pocket and Its Implications for AAV Vector Biodistribution

Jacob A. Hoffman, Joshua J. Sims, James M. Wilson
University of Pennsylvania, Philadelphia, PA

The natural tropism of adeno-associated viruses (AAVs) for the liver represents a major impediment to the expansion of AAV gene therapy into clinical indications affecting non-liver peripheral organs such as the heart. Recent deaths and adverse events associated with liver toxicity in high-dose AAV gene therapy trials targeting peripheral organs exemplify this problem. Thus, there is a need for novel AAV vectors that are detargeted from the liver but retain the ability to transduce peripheral organs. The primary cellular receptor for AAV9 is galactose, the penultimate glycan residue of the N- and O-linked glycan chains that adorn the surface of all cell types. Our group initially described the galactose-binding pocket on the surface of AAV9 as a cluster of five amino acids, N271, D272, Y446, N470, and W503. Previous work from our lab showed that alanine substitutions at these positions ablate *in vitro* transduction. Moreover, our unpublished data show that the substitution W503A reduces *in vivo* transduction to 0.02x expression in mouse liver and 0.15x expression in mouse heart compared to AAV9. Data from other groups suggest that amino acid substitutions other than alanine can confer similar levels of liver detargeting while preserving relevant levels of peripheral transduction. Thus, we performed multiple screening rounds of an AAV library containing variations at the AAV9 galactose binding site and identified a vector with a 2.7x enhancement in cardiac transduction with a concomitant 0.43x decrease in liver transduction in mice. The generation of liver-detargeted AAV vectors that exhibit enhanced cardiac transduction represents important progress in improving vector specificity and safety.

995 The Impact of the *In Vitro* Diagnostic Medical Devices Regulation (EU) 2017/746 on Gene Therapy Medicinal Product Developers

Claire Marasco, Juan Ruiz, Ashley Shay, Christopher J. Shilling
Forge Biologics, Grove City, OH

The EU In Vitro Diagnostic Medical Devices Regulation (IVDR) (2017/746) was developed to specify the safety, integrity, and quality requirements for any in vitro diagnostic (IVD) manufactured or used in the EU. The regulation carries few exemptions, including none for early-phase clinical studies, orphan products, or gene therapy medicinal products (GTMPs). It came into effect on 25 May 2017 with a 5-year transition period. With the end of the IVDR transition period on 26 May 2022 and the mandatory submission of initial clinical studies under the EU Clinical Trial Regulation (CTR) (536/2014) after 31 January 2023, the IVDR poses major potential hurdles to the development of many GTMPs in the EU. For GTMPs, anti-drug antibody (ADA) assays are commonly used to determine patient eligibility for clinical trials by characterizing patient immunogenicity to a viral vector capsid and/or the expressed transgene. These assays are considered in vitro diagnostics (IVDs) or companion diagnostics (CDx) and under the IVDR are subject to the full scope of the regulation. This means that the submission and acceptance of clinical performance study plans are needed to initiate participant enrollment in the clinical trial in addition to the approval of the clinical trial application (CTA). In the case of ADA assays for orphan products, there are limited published data or commercial assays to justify an alternative to the development of a CDx, and the ability to assess clinical performance in the patient population is significantly challenged due to limited access to low prevalence patient populations. In light of this transition, Forge will discuss some important points for GTMP developers to consider before initiating a clinical trial in the EU that uses a CDx or IVD. These include opportunities for scientific advice during the development of your performance study and CTA strategy, collection of robust analytical performance data during assay development, considerations for the design of a clinical performance study (including using the trial itself), and advanced planning for late-stage development of the CDx, like potential partnership opportunities. This presentation will also include a comparison to IVD and CDx regulations in the US. The IVDR adds a layer of complexity to the conduct of GTMP clinical trials in the EU and necessitates that sponsors give it ample consideration early in the development of their clinical trial strategy.

997 Validation of an Analytical Method for Lentivirus Physical Concentration Using Videodrop (ILM) Following ICH Guidelines

Marie Berger
MYRIADE, Paris, France

The EMA guidelines for quality control of gene therapy medicinal products recommend controlling the particle number and size of viral vectrs drug substance (DS), drug product (DP) and critical intermediates in the viral vector process. Videodrop is an innovative system based on Interferometric Light Microscopy (ILM) which measures nanoparticle concentration and size quickly and easily. it cab be included in the quality control plan. For this purpose, analytical methods must be validated following ICH Q2 guidelines. This study proposes evaluating the linearity and precision of Videodrop by analyzing lentivirus samples from various stages of bioproduction. The validation study includes two different bioprocesses and more than 200 measurements. The results of this validation study show a very good precision with CV<15% and excellent linearity with R^2 >0,97. Results are favorable and hold promise for GMP method validation for gene therapy products with Videodrop. Moreover, the very limited number of parameters and ease of use allow a very high reproducibility allowing easy QC transfer.

998 Mouse CD123-CAR T Cells Elicit Robust Anti-AML Activity without HSC Toxicity in Syngeneic Models

Jaquelyn T. Zoine[1], Sarah E. Moore[1], Jeremy C. Crawford[2], Chris Nevitt[1], Deanna M. Langfitt[1], Juan M. Barajas[3], Sherif Abdelhamed[3], Ilaria Iacobucci[3], Nicole L. Michmerhuizen[3], Dalia Haydar[1], Giedre Krenciute[1], Charles G. Mullighan[3], Jeffery M. Klco[3], Stephen Gottschalk[1], Paul G. Thomas[2], M . Paulina Velasquez[1]
[1]Bone Marrow Transplant and Cellular Therapy, St. Jude Children's Research Hospital, Memphis, TN,[2]Immunology, St. Jude Children's Research Hospital, Memphis, TN,[3]Pathology, St. Jude Children's Research Hospital, Memphis, TN

The use of chimeric antigen receptor (CAR) T cells specific for acute myeloid leukemia has been hampered by limited expansion and efficacy in clinical trials, despite robust antitumor activity in preclinical models. Understanding the interactions between CAR T cells and the highly immunosuppressive acute myeloid leukemia (AML) tumor microenvironment (TME) is essential to improving this therapy. To date, there are no syngeneic AML models using AML-CARs that mimic the aggressive TME. Here, we established the first mouse CD123 (mCD123)-CAR T cell immunocompetent system. We designed 4 second generation mCD123-CARs with single chain variable fragments (scFvs) derived from biopanning of a mouse phage display library on recombinant mCD123. Only one of the CARs was successfully expressed on activated mouse T cells from splenocytes as detected by F(ab')2 (55.8±11.5% N=7,) or recombinant mCD123 (59.0±12.1% N=6). To measure antigen specificity, we expressed full-length mCD123 on 2 mouse leukemia cell lines: C1498, a spontaneous myelomonocytic AML cell line, and an Arf-null, BCR-ABL1 pre-B-ALL (B-ALL^{123+}). We observed significantly increased cytokine secretion and cytolytic activity in mCD123-CAR T cells when cocultured in the presence of CD123+ targets in comparison to controls (N=6, $p<0.01$). Antitumor activity was maintained in repeat stimulation assays for up to 5 stimulations. *In vivo,* mCD123-CAR T cells had significant anti-leukemia activity against B-ALL^{123+} resulting in a prolonged survival advantage in comparison to controls (N=5 / group, $p<0.001$). In addition, we analyzed a panel of virally induced NUP98::KDM5A AMLs generated by transduction of mouse hematopoietic progenitor cells and determined all samples naturally expressed mCD123 antigen at different densities (range 38-77%; N=4). We evaluated the anti-leukemic activity of mCD123-CAR T cells in vivo. Our data show significantly reduced leukemia burden ($p<0.001$) and extended survival ($p<0.01$) in mice treated with 5×10^6 mCD123-CAR T cells compared to control CAR T cells. We detected mCD123-CAR T cells in treated mice using RNAscope probes. To measure toxicity, we injected non-tumor bearing mice with 5×10^6 luciferase modified mCD123-CAR T cells. We monitored expansion for 10 days and analyzed bone marrow and spleen on day 10 using flow cytometry and CFU assays. We noted no differences in toxicity profile of mCD123-CAR compared to controls. Next, we delineated the TME in our models using flow cytometry and single cell transcriptomic data from bone marrow of mice injected with B-ALL^{123+} +/- mCD123-CAR T cells ~7 days post T cell injection. Our findings reveal that the TME of our immune competent leukemia CAR T cell therapy models recapitulate human disease, showing an increase in dying tumor cells within the bone marrow of mice in the treated group, with a number of other populations (e.g. dendritic cells, regulatory T cells) approximating the tumor-only microenvironment profile. We have developed the first functional mCD123-CAR T cells targeting mouse AML and ALL and have shown their activity in immunocompetent models, with potent anti-leukemic activity *in vitro* and *in vivo* with minimal toxicity. Our model will provide insight into the impact of the AML TME on CAR T cell functionality and inform future strategies to improve CAR T cells in the immunosuppressive TME.

999 Variant-Aware Off-Target Analysis of Therapeutic CRISPR Gene Editing Targets

Thomas E. Mullen, Alyssa Ferreira, Ashley Lester, Shankar Shankaracharya, Divya Ravindran, Sophia Oladimeji, Andrew Hollinger, Vijetha Vemulapalli, Douglas R. Smith
SeQure DX, Waltham, MA

CRISPR gene editing therapy holds tremendous promise for the treatment of inherited genetic diseases. Many genetic disorders display population-specific differences in prevalence. Sickle Cell Disease (SCD) and *APOL1*-mediated kidney disease represent two examples of such genetic diseases with enrichment in individuals of African ancestry. The FDA has recently emphasized the importance of genetic analysis to understand the effects of human variation on editing activity across intended to treat populations in its draft guidance for gene editing therapy development. In this study, we applied oligonucleotide enrichment and sequencing (ONE-seq) in a variant-aware manner to identify candidate off-target sites with variable editing potential and allele frequency across major human populations. We assessed two gene editing targets that are currently being evaluated in human subjects in early-stage clinical trials:

one in *BCL11A*, a regulator of the developmental switch from gamma- to beta-globin for treatment of SCD and β-thalassemia, and one in *PCSK9*, a regulator of LDL receptor and plasma cholesterol levels for treatment of hypercholesterolemia. Phased variants derived from the 1000 Genomes and Human Genome Diversity Project data sets (3,433 genomes) were evaluated for their quantitative effect on Cas9 gene editing in vitro. ONE-seq analysis identified a large number of candidate off-target sites in which variants either increased or decreased in vitro editing frequency substantially compared to the reference sequence. Many of these variant-specific off-targets had remarkable effect sizes, often over 1000-fold in some cases. The nominated sites were subsequently analyzed to identify those where increased editing at variant sites could potentially alter the function or expression of associated genes resulting in significant biological impact. Together, these results underscore the critical importance of including genetic diversity across human populations as a consideration in evaluating potential off-target gene edits.

1000 Dissecting the Epigenetic Regulation of Hemoglobin Expression to Unravel Novel Curative Options for β-Hemoglobinopathies

Letizia Fontana[1], Simone Amistadi[1], Chiara Magnoni[1], Panagiotis Antoniou[1], Faiq Ali[2], Melissa Whitehead[2], Claudio Mussolino[2], Annarita Miccio[1]

[1]Imagine Institute, Paris, France,[2]Medical Center - University of Freiburg, Freiburg, Germany

β-hemoglobinopathies are severe genetic diseases caused by mutations affecting the production of the β-globin chain. The clinical severity of these pathologies is mitigated by the co-inheritance of mutations that reactivate *γ-globin*(*HBG*) genes expression and result in elevated production of fetal hemoglobin (HbF) in adults, a condition named hereditary persistence of HbF (HPFH). Multiple strategies to reactivate *HBG* were described, such as the introduction of HPFH mutations in their promoters that result in *de novo* binding sites for transcriptional activators. HbF reactivation in adult cells can also result from down-regulation of *BCL11A*, a gene encoding a major *HBG* transcriptional repressor.Allogenic hematopoietic stem/progenitor cell (HSPC) transplantation is the only definitive therapy for patients with β-hemoglobinopathies. In the absence of a compatible donor, transplantation of corrected autologous HSPCs represents an attractive therapeutic option. Lentiviral vectors (LV) or CRISPR/Cas9 have been exploited to restore β-globin expression. However, genotoxicity due to the semi-random LV integration in the host genome or to unwanted activity of CRISPR/Cas9, raises safety concerns for clinical applications. Therefore, novel and safer therapeutic strategies for β-hemoglobinopathies need to be developed. We investigated the epigenetic regulation of *HBG* and *BCL11A* to develop novel therapies via targeted epigenome editing with the goal of modulating gene expression without modifying the underlying DNA sequence. To this aim, we analyzed epigenetic marks at two key *cis*-regulatory regions, the *HBG* promoters and the *BCL11A*enhancers, in patients' HSPC-derived erythroid cells. Bisulfite sequencing revealed high DNA methylation of the *HBG* promoters in erythroid cells expressing mainly adult hemoglobin. On the contrary, introduction of HPFH mutations that recruit the KLF1 transcriptional activator at the *HBG* promoters led to reduced DNA methylation and high HbF production. These results indicate a role for DNA methylation in *HBG* repression which, however, can be reverted in adult erythroid cells to induce HbF expression. The *BCL11A* enhancers were modestly methylated in adult erythroid cells that express *BCL11A*. CRISPR/Cas9-mediated inactivation of activator binding sites mapping to these enhancers led to increased DNA methylation associated with *BCL11A* downregulation and HbF reactivation. These findings suggest that DNA methylation can negatively impact the activity of *BCL11A* enhancers and can be modulated to reactivate HbF.Furthermore, we used ChIP-seq to profile the presence of defined histone marks at the two *cis*-regulatory regions analyzed. Deposition of active histone modifications correlated well with the activity of the *HBG* promoters and *BCL11A* enhancers in primary adult erythroblasts. Indeed, in fetal primary erythroblasts expressing γ-globin, *HBG*promoters showed high levels of histone 3 lysine 27 acetylation (H3K27ac) and lysine 4 trimethylation (H3K4me3), typically associated with active transcription, while these modifications were absent in adult primary erythroblasts that do not express γ-globin. Current experiments aim to exploit designer epigenome modifiers to manipulate the epigenetic architecture of the *HBG* promoters and the *BCL11A* enhancers to achieve persistent HbF expression in patients' HSPC-derived erythroid cells. We anticipate that the epigenome editing strategy pursued here overcomes genotoxicity risks and offers a potentially safer approach for the future treatment of β-hemoglobinopathies.

1001 Intra-Thalamic Targeting for Widespread Brain Biodistribution of AAV-Based Gene Therapies

Nicholas J. Gattone, Tyler Demarest, Karthik Ramanathan, Yulia Dzhashiashvili, Eric Wildon Kostuk, Bo Wang, Mohamad Nayal, Esteban A. Engel, Renee Gentzel, Maria Grazia Biferi, Elizabeth Ramsburg

Spark Therapeutics, Philadelphia, PA

Harnessing the full power of gene therapy (GTx) heavily relies on targeting essential tissues and cellular populations with specificity and sensitivity. This is particularly complex in the central nervous system (CNS) as many CNS disorders require widespread biodistribution over multiple brain regions for therapeutic efficacy. While intra cerebrospinal fluid administration (Intracerebroventricular, Intracisterna magna) is feasible, and blood-brain barrier crossing capsids for systemic injection are in development, these methods pose a greater risk of unwanted peripheral tissue transduction. Another approach is to take advantage of the native neuronal projections to and from major brain network hubs and utilize them to deliver AAV GTx's to anterograde and retrograde connected brain regions to reduce the risk of peripheral tissue transduction. To this end, we have evaluated several intra-thalamic injection coordinates with the goal of wide-spread cortical and hippocampal transduction using AAV serotype 9 expressing enhanced green fluorescent protein (AAV9.eGFP) constructs. We first utilized anterograde and retrograde tracers (dextran AF-647 and CTB-AF555, respectively) to determine coordinates resulting in cortical and hippocampal transduction using traditional immunofluorescence or whole brain tissue clearing, followed by light sheet microscopy imaging (LifeCanvas Technologies) and analysis. We found distribution of the tracers along the antero-retrograde thalamic projections throughout the anteroventral regions of cortex with each of our tested stereotaxic

coordinates. Additionally, AAV9.eGFP transduction using similar coordinates closely recapitulated the biodistribution observed using the tracers. Furthermore, we tested whether single stranded (ssAAV) and/or self-complimentary AAV (scAAV) genomes impact the biodistribution of eGFP expression using the optimized intra-thalamic coordinates. We found that scAAV had superior biodistribution to the cortex and hippocampus when compared with ssAAV. These findings have broad implications for CNS GTx therapeutics and are informative for CNS diseases that require broad brain transduction.

1002 An Innovative Platform Approach for the Development of *Ex-Vivo* Gene Therapies for the Treatment of Lysosomal Storage Diseases with Skeletal Involvement

Stefania Crippa[1], Serena Scala[1], Claudia Forni[2], Pamela Quaranta[3], Gaia Alberti[1], Margherita Berti[1], Ludovica Santi[4], Giada De Ponti[5], Raisa Jofra-Hernandez[1], Luca Basso Ricci[1], Rilievo Angela[1], Ilaria Visigalli[6], Antonella Paoli[7], Giulia Consiglieri[8], Francesca Tucci[8], Paola Albertini[9], Amelia Morrone[10], Rossella Parini[1], Bernhard Rudolf Gentner[11], Alessandro Aiuti[5], Maria Ester Bernardo[5]

Lysosomal storage diseases (LSDs) are characterized by the accumulation of undigested macromolecules causing severe multi-organ damage, which the currently approved therapies fail to cure. Previous data obtained by our Institute proved the safety and efficacy of Hematopoietic Stem and Progenitor Cell-Gene Therapy (HSPC-GT) for the treatment of other LSDs. Building on this experience and the common pathological mechanisms of LSDs, we are proposing HSPC-GT to cure a group of rare/ultra-rare LSDs with skeletal involvement (Mucopolysaccharidosis IVA, Mucopolysaccharidosis IVB, Alpha-Mannosidosis) by using a standardized process in the framework of an innovative platform approach. We optimized Chemistry, Manufacturing and Controls, Non-clinical and Clinical development plans to generate a platform dataset complemented by specific disease data to generate a single combined Clinical Trial Application for clinical testing, moving from the "1-to-1 sequential" drug development to the "simultaneous and parallel" development approach. To this aim, we generated 3rd-generation lentiviral vectors encoding for each specific enzyme (LV-GALNS, -GLB1, and -MAN2B1) to transduce human HSPCs. Transduced cells showed proper clonogenic and proliferative capacity and significantly overexpressed the functional enzyme. Preliminary data also indicated that the enzymatic activity was restored in patients' derived fibroblasts exposed to the conditioned medium from LV-GALNS and MAN2B1 transduced human HSPCs-derived myeloid cells. Importantly, osteoclasts derived from LV-GALNS and GLB1 transduced cells abundantly secreted the different lysosomal enzymes, possibly serving as a resident enzyme source for skeletal cross-correction. Moreover, LV-GALNS transduced HSPCs engrafted and differentiated in the hematopoietic organs when transplanted in NSG mice. Altogether, our pre-clinical data support the HSPC-GT development for the platform LSD treatment.

1004 Anc80 Delivery of the RPGRIP Gene Stabilizes Functional Vision Decline in a Genetic Mouse Model

Kathryn Post DeMott, Ashley Winslow

Odylia Therapeutics, Atlanta, GA

Homozygous and compound heterozygous loss-of-function mutations in *RPGRIP1* are associated with several rare retinal dystrophies, most commonly with the diagnosis of Leber congenital amaurosis type 6 (LCA6) but also associated with cone-rod dystrophy 13 (CORD13) and forms of juvenile-onset retinitis pigmentosa (jvRP). LCA6 presents in early childhood with the most severe forms appearing as early as birth. Odylia Therapeutics is developing a gene therapy to treat vision loss caused by *RPGRIP1* mutations. This gene therapy will utilize the Anc80 AAV capsid to deliver a functional copy of the *RPGRIP1* gene to photoreceptors. To-date, strong proof-of-concept data has been generated in a mouse model of LCA6 and preliminary non-human primate safety data supports vector tolerability at the doses tested. Odylia is currently in the final stages of preclinical testing while planning for IND submission. Despite that the estimated prevalence of LCA6 in the United States is approximately 450-1,350 individuals, Odylia champions this and other programs by partnering with a diverse network of collaborators to ensure that promising therapeutics aren't left behind.

1005 Synthetic DNA and Targeted Non-Viral Delivery Systems for Genetic Correction of Duchenne's Muscular Dystrophy

Amy Walker, Amine Bouchareb, Heikki Lanckriet, Elena Dyankova

4BaseBio, Cambridge, United Kingdom

Duchenne muscular dystrophy (DMD) is a severe monogenic disease caused by mutations in the gene encoding dystrophin. While several trials are on-going, including AAV-mediated delivery of a truncated micro-dystrophin, no clinically effective therapy is available to date. The emergence of CRISPR-Cas and associated editing technologies provide an attractive therapeutic option for the treatment of DMD, however delivery to muscle remains a challenge. 4basebio has developed a proprietary, non-viral nanoparticle that targets muscle cells with high specificity and low immunogenicity, allowing for repeat dosing. The Hermes™ particle is payload agnostic and has been used to deliver DNA, mRNA and proteins to muscle cells both *in vitro* and *in vivo*. In addition, we have a scalable enzymatic synthesis process for the production of linear DNA constructs via our Trueprime amplification technology. The oeDNA produced is devoid of any bacterial backbone and the manufacturing process circumvents cumbersome fermentation processes required for plasmid DNA, is size and sequence independent, and ideally suited for DNA repair templates used in gene editing. In this study, we utilised the muscle targeting particle to deliver Cas9 protein

with an sgRNA targeting the DMD gene in C2C12 myoblasts and myotubes. Particles had highly favourable biophysical characteristics, stability, encapsulation of payload, and achieved high KO efficiency in relevant cell models. To investigate a gene-integration approach using our plasmid-free synthetic DNA technology, we designed an oeDNA™ template encoding the cDNA sequence of the *Dystrophin* gene with flanking homology arms. The co-delivery of template DNA along with the RNP complex encapsulated in our Hermes™ nanoparticle resulted in a successful integration of the oeDNA template, and enhanced protein expression *in* vitro. Mouse studies confirming these findings are ongoing. The present study provides proof-of-concept for the use of Hermes™ particles to deliver RNP + donor templates to reframe or fully replace a dysfunctional gene, offering a promising approach for DMD therapy.

1007 Allogeneic Class I MHC Gene Therapy Induces Tumor Rejection in a Murine Model of Hepatocellular Carcinoma

Chelsae Dumbauld[1], Ioanna Papacharalampous[1], Oumar Barro[1], Mitesh Borad[2], Bolni Marius M. Nagalo[3]

[1]Mayo Clinic, Scottsdale, AZ,[2]Mayo Clinic Cancer Center, Scottsdale, AZ,[3]University of Arkansas for Medical Sciences, Little Rock, AR

The incidence of hepatocellular carcinoma (HCC) in the United States has almost tripled in the last 20 years. Recently, immune checkpoint inhibitors have improved outcomes for treatment of HCC. However, the efficacy of immune checkpoint blockade can be limited by an inherently immunosuppressive environment within the liver, as well as tumor cell downregulation of class I MHC to evade cytotoxic T cell detection. Another promising treatment approach for HCC is gene therapy, which can either target a tumor specific gene or induce expression of immune modifiers.In order to overcome immune ignorance of HCC tumors, we formulated a gene therapy mediated approach to induce expression of Class I MHC on tumor cells. We hypothesized that **gene therapy induced expression of allogeneic class I MHC on cancer cells** would lead to an immune response towards the tumor, in a manner similar to graft rejection. We therefore engineered both an integrating lentivirus (LV) and a non-integrating AAV serotype 8 (AAV8) platform, each encoding either matched (H-2Kb) or allogeneic H-2K (H-2Kk and H-2Kd) murine class I MHC alleles along with a luciferase reporter. We first validated that our viral vectors induced detectable expression of foreign MHC following LV infection in HCC cell lines *in vitro.* We then established a murine syngeneic model of HCC in C57Bl/6 mice and treated tumor-bearing mice with three intratumoral doses of viral vector. We assessed therapeutic efficacy by comparing tumor growth of MHC-match and MHC-mismatch treated groups to luciferase-only vector and saline control conditions. We were able to detect efficacious gene delivery and *in vivo* expression by luciferase activity in treated murine tumors. Both gene therapy approaches were well tolerated in mice, with no observable detriments in mouse body weight or behavior. Tumor rejection and improved long-term survival was observed in 80% of the H-2Kk LV treated mice and 43% of H-2Kd LV treated mice. Substantial difference in tumor growth was observed in both H-2Kk AAV8 (62.9% mean tumor inhibition) and H-2Kd AAV8 (84.8% mean tumor inhibition) treated mice after three doses. We also performed immunoprofiling of tumor infiltrating lymphocytes at endpoint in remaining tumors and observed tumor infiltrating CD8 T cells were increased in H-2Kk AAV8-treated mice. Although gene therapy mediated expression of self MHC in the tumors exhibited a modest effect on tumor growth in LV and AAV8 treated mice, the results were more profound when inducing allogeneic MHC expression.These results show for the first time that gene therapy induced expression of allogeneic class I MHC can stimulate tumor rejection in a murine model of hepatocellular carcinoma. Further work will improve upon viral targeting to HCC to allow for intravenous or peritoneal delivery, as well as combination therapy with immune checkpoint inhibitors.

1008 Genetic Medicine Using a PLV Approach Reduces Frailty and Improves Healthspan

Hank Garcia[1], Douglas Brown[2], Prakash Bhandari[3], Marco Malavolta[4], Arun Raturi[3], Matthew Scholz[5], John Lewis[1,2,3]

[1]Oisin Biotechnologies, San Diego, CA,[2]Department of Oncology, University of Alberta, Edmonton, AB, Canada,[3]Entos Pharmaceuticals, Edmonton, AB, Canada,[4]Istituto Nazionale Riposo e Cura Anziani (INRCA), Ancona, Italy,[5]Oisin Biotechnologies, Seattle, WA

Physical frailty and sarcopenia affect half of all elderly individuals and can lead to poor quality of life disability, and death. It is also linked to cardiovascular diseases, respiratory disease, and cancer in middle age, with the underlying mechanisms still being investigated. Senescence, a cell fate characterized by quiescence and secretion of pro-inflammatory molecules, is a hallmark of aging that is implicated in a variety of age-related pathologies. Eliminating senescent cells (SCs) in vivo using transgenic mice have demonstrated significant improvements in healthspan and amelioration of age-related degeneration, including physical frailty and sarcopenia. However, since this requires genetic engineering of the organism from the embryo, there is broad active development on senolytic drugs. This new class of therapeutics are designed to mimic the effect and increase health span. The first generation of senolytics have been repurposed drugs with off-target effects and tolerability limitations. Thus, next generation interventions require better specificity and tolerability. Herein we discuss senescence-dependent and senescence-independent clinically viable gene therapies to combat frailty and improve muscle function. The first consisting of a suicide gene under a senescent cell promoter delivered in vivo with Proteo-Lipid Vehicles (PLVs). These PLVs employ fusion-associated small transmembrane (FAST) proteins that can efficiently transduce a wide range of cells in vivo. Selective ablation of target cells is then achieved through the expression of a potent pro-apoptotic transgene driven by a specific senescence-associated promoter such as p16Ink4A or p53. The second consisting of expressing the myostatin and activin antagonist, Follistatin, under the control of a promoter specific to the liver where it is majorly expressed for muscle growth. We examined the effect of senolysis by our FAST-PLV senolytic therapy on healthspan utilizing a battery of clinically translatable metrics for physical function and frailty. Naturally Aged C57/B6 mice 24-26 months of age were treated monthly with senolytic PLVs encoding a suicide gene driven by senescence-associated promoters p16 or p53. Clinical frailty measured by deficit accumulation was assessed using 31 observational metrics, physical function was assessed with a battery of tests (grip strength, rotarod, treadmill, and open field), and heart function was assessed using ECG. Aged mice treated with senolytic

PLVs showed significantly reduced senescent cell burden body wide. Treatment with senolytic PLVs increased median post-treatment survival by 160%, lowered clinical frailty, and improved physical and heart function. Additionally, spontaneous tumor burden in these mice was reduced by 60%. Our data shows that senolytic FAST-PLVs improved healthspan and reduced frailty in naturally aged mice. We separately measured the effect on muscle growth by a FAST-PLV Follistatin therapy. Up to 9 months after one treatment, muscle weight and fiber size were significantly increased resulting in increased body weight and functional grip strength. In summary, our approaches represent a first-in-class therapeutic that targets cells based on transcriptional activity, rather than surface markers or metabolism, and represents a viable strategy for treating age-related diseases such as physical frailty and sarcopenia.

1010 Development of Rational Formulation for the Delivery of AAV Viral Vector for Treatment of Heart Disease

Joe Woods

Process Development, Tenaya Therapeutics, South San Francisco, CA

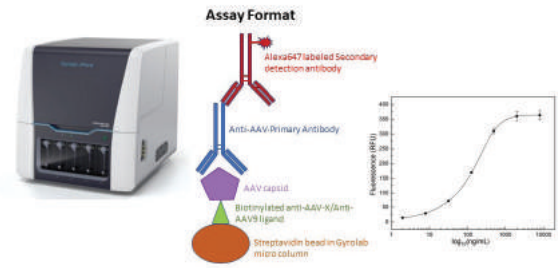
Adeno-associated virus (AAV) has emerged as a leading platform for gene delivery for treating genetic heart diseases. However, due to challenges associated with manufacturing scale up and long term storage, AAV can be prone to degradative, aggregative, and adsorptive loss which can negatively impact the purity, potency, and quality of the final drug product. Additionally, for the treatment of heart disease in particular, depending on route of administration, conventional drug product formulation excipients, such as phosphate and acetate, can have negative effects on heart function, which limit the options for excipient selection. Using rational design, Tenaya Therapeutics, Inc. has developed a robust formulation for AAV that is stable under different storage temperatures and stress conditions. Additionally, the formulation is photostable and supports in-use conditions including multiple freeze-thaw cycles, and is compatible with devices for both intravenous and local delivery via cardiac catheters, greatly enhances clinicians' ability to bring and deliver AAV viral vector drug products to patients suffering from genetic heart diseases.

1011 Development of GyroLab *In Vitro* Immunoassay to Detect Pre Existing Antibodies Against AAV

Aruni Karunanayake M, Christoph Eberle, Robert Mihalek, Kenneth Munroe, Emma Buck

Charles River Laboratories, Worcester, MA

Recombinant Adeno Associated Viruses (AAV) are a commonly used gene delivery viral vector system to effectively introduce foreign genes into a broad range of cells and tissues. These gene delivery tools are widely explored in novel strategies for treating human diseases associated with blood, central nervous system and neuromuscular disorders or cancer. *In vivo* gene therapies approved in the US and Europe based on this approach have yet indicated minimal immunogenicity, minimal genome integration, and no pathogenicity. Previous exposure to naturally occurring AAVs results in pre-existing immunity that limits the efficacy of gene therapy and represents a potential safety concern. Therefore, it is important to screen for pre-existing AAV antibodies prior to gene transfer therapies. For most AAV gene therapy candidates currently in development neutralization assays are used to determine anti AAV antibody levels. These cell-based assays pose challenges such as lack of reproducibility, time consumption, and limitations in screening large sample numbers. An ELISA based method is an alternative that can be developed to measure total antibody levels against a specific serotype. In general, these types of *in vitro* assays are sensitive, reproducible, rapid, and can be validated to provide precise and accurate measurements even at high throughput demands. Therefore, we have developed an ELISA based anti-AAV antibody detection method using the automated GyroLab immunoassay platform that requires minimum sample volume while ensuring precision and accuracy of measurements. In this method, AAV capsid serotypes are immobilized on streptavidin-coated bead beds within the microcolumn of a GyroLab Bioaffy™ CD using AAV specific biotinylated ligands. The ratio of biotinylated ligands to form each specific complex is optimized. Primary antibodies against specific serotypes are captured by these immobilized AAV particles and detected by an Alexa Fluor 647-labeled secondary IgG antibody of the intended testing species. The method was qualified to detect anti-AAV8 antibodies between 7.8 ng/mL and 2000 ng/mL, anti-AAV9 antibodies between 16 ng/mL and 10000 ng/mL, and anti-AAV2 antibodies between 90 ng/mL and 25000 ng/mL, respectively. Anti-AAV antibody levels can be determined with ±20% accuracy of the nominal concentration and with ≤20% precision (%CV). These GyroLab immunoassays are capable of detecting and quantifying AAV antibodies in different matrices from multiple species such as human, mouse and non-human primates. Assay performance was determined using AAV positive and negative non-human primate sera obtained from a commercial vendor. Both calibrator standards and quality control (QC) samples are used for sample data acceptance within a single run. This established *in vitro* method can be utilized in preclinical studies to detect and quantify both pre-existing AAV antibodies as well as potential immunogenicity due to an AAV based gene therapy.



1012 Process Development for the Parallel Purification of Multiple Viral Vector Samples

Md Nasimuzzaman[1], Anthony Kupchek[1], Sergio Salazar[1], Colleen Richards[1], Jennifer Kandel[1], Trevor Marshall[1], Chad MacArthur[1], Steven Millan[2], Hetal Brahmbhatt[2], Jessica M. Tate[2], Richard O. Snyder[2], Uma Lakshmipathy[1]

[1]Thermofisher Scientific, San Diego, CA,[2]Thermofisher Scientific, Alachua, FL

Adeno-associated virus (AAV) and lentivirus (LV) vectors have emerged as essential tools for gene and cell therapy applications. The purity of viral vector particles is critical for achieving effective transduction in cells while minimizing cytotoxicity. However, the purification of viral vectors is challenging when multiple vectors are processed simultaneously in parallel during the screening and selection of different vector genome configurations. A bottleneck to this approach is the current use of single-column chromatography systems that are not amenable to parallel processing. Therefore, there is a need to develop high-throughput chromatography methods capable of purifying multiple viral vector samples simultaneously in parallel to significantly reduce the overall labor, time, and resources. Our study uses the Protein Maker (PM) and AKTA PCC 75 that have been developed to provide an automated system capable of purifying multiple protein samples in parallel and to scout multiple purification strategies. The PM system has been designed and optimized to enable highly efficient, parallelized purification of proteins. For example, using the standard single-column 4-step single-channel method, the PM will purify up to 24 samples under one method in parallel, or 1-4 different samples on up to 6 different column types under 6 different method variations in parallel. AKTA PCC 75 is useful for the purification of up to 3 samples simultaneously. However, it has not been reported for AAV and LV vector purification using the PM or AKTA PCC 75. Here, we have used the PM and AKTA PCC 75 to purify multiple AAV and LV vector samples in parallel. We have produced AAV and LV vectors by transient transfection of HEK 293 cells using AAV-Max and LV-Max transfection reagents, respectively. Purification of these vectors was carried out by loading multiple vector samples in parallel onto their corresponding column using Protein Maker or AKTA PCC 75 separately. After elution, the vector samples were concentrated and formulated for gene therapy applications. The yields and purity of our viral vector samples were comparable to the conventional single-channel chromatography-based purification methods. Results from these successful studies demonstrate that a high-throughput viral vector purification procedure that can be useful for screening and candidate selection during process development and can be translated to Current Good Manufacturing Practices (cGMP) production for manufacturing clinical-grade vectors.

1013 Quantifying Indel Frequencies of Novel Nucleases with Unknown Cleavage Sites

Tess Torregrosa, Youngji Na, Eugenia Lyashenko, Sourav R. Choudhury

AAV Technologies Laboratory, Genomic Medicine Unit, Sanofi, Waltham, MA

Nucleic acid-guided nucleases that edit polynucleotide sequences with high precision are characterized by their cleavage site relative to a target sequence and editing window. Existing next generation sequencing (NGS) analysis pipelines to quantify nuclease induced insertion and deletions (indels) assume that the cleavage site and editing window are established. However, for discovery and engineering of novel nucleases these properties may not be defined, which complicates editing analysis with standard tools. Here we establish Na-Lyashenko pipeline, a comprehensive and unified NGS-based workflow to characterize indels in a nuclease-agnostic manner. First, our pipeline sets rigorous QC metrics for NGS sequencing of the samples and visualizes read alignments to the amplicon. Second, we identify data-driven parameters for each sample depending on the combination of read length, amplicon prep, and nuclease to accurately quantify indels in the aligned reads. Thirdly, we customize parameters in a publicly available CRISPResso2 tool to quantify indels in a window centered on the target sequence and spanning +/-5 bp from each end of the sequence. We validated Na-Lyashenko pipeline with SpCas9 edited samples with a known target sequence and cleavage site (-3bp) against the default CRISPResso2 parameters. We then took highly edited samples (>80%) generated by a novel Cas12a nuclease with an unknown cleavage site and diluted defined ratios with non-edited samples. We found the observed indel percent of these mixed samples closely correlated with the expected indel percentage. Moreover, we leveraged Na-Lyashenko to quantify larger insertions (>10 nucleotides) with a 21-nucleotide library insertion and serially spiked-in a defined sequence. We found the observed spike-in sequence percent agreed with the expected spike-in percentage. The results demonstrate that the Na-Lyashenko pipeline can accurately quantify indels without the need for a defined cleavage site or specific editing window. Taken together the Na-Lyashenko pipeline may facilitate data analysis of indels to help characterize editing by novel nucleases.

1014 Insect Cell Baculovirus Expression Plaform for Large Scale Producton of rAAV

Sandra Bennun

uniQure, Lexginton, MA

Recombinant adeno-associated virus (rAAV) has become one of the main platforms for the development of novel human gene therapies. The ability to make high-quality vectors can be achieved using the baculovirus expression vector system using host insect cells. This approach offers a more scalable methodology to rAAV production potentiating their application for safe and cheap manufacturing. The successful scale-up production of rAAV vectors using the baculovirus expression system to supply the required genes is demonstrated at 500L scale. uniQure approach, based on Pilot Plant experience for large scale production of rAAV vectors in a Baculovirus expression vector/insect

cell system provides insights into the role of insect cell technology in the development and production of scalable manufacturing rAAV processes.

1015 Dose Control of rAAV Transgenes by Bioorthogonal Small Molecule Epigenetic Recruiters

Sara R. Wasserman, Jessica Umana, Caroline A. Foley, Lindsey I. James, Matthew L. Hirsch, Nathaniel A. Hathaway

University of North Carolina at Chapel Hill, Chapel Hill, NC

Adeno-associated virus (AAV) is one of the most frequently used vectors for the therapeutic transfer of genetic material. Current AAV gene therapy clinical trials seek to treat a diverse set of human diseases, from cancer to congenital genetic disorders. However, the application of AAV based therapies in some disease contexts is limited by insufficient transgene expression in targeted tissues. Our group has developed a chemically-based, bioorthogonal system that can epigenetically control the dose of genetic targets. The technology uses substrate-specific bifunctional small molecules, called chemical epigenetic modifiers (CEMs), to recruit endogenous epigenetic machinery to targeted genes. When paired with synthetic DNA-targeting modules such as dCas9 or zinc fingers (ZFs), CEM technology is capable of tuning genetic expression in a reversible and target-specific manner. To achieve dose control of AAV transgene expression using CEM technology, we developed a series of ZF-based, minimal autogenous regulatory cassettes that can be embedded into single-stranded vectors and retain 2.8-3.1 kb for therapeutic transgene payloads. We demonstrate that these autogenous CEM cassettes can efficiently control transgene expression in a CEM-dose dependent manner *in vitro*. In human cell lines, treatment with a bioorthogonal bromodomain containing protein 4 (BRD4) recruiter CEM induces AAV transgene expression by 10-fold. Upregulation of AAV expression by CEMs is shown to be reversible, to be CEM-dose dependent, and to scale with viral titer. This novel chemical approach to finely control and enhance expression of AAV transgenes may improve the safety and efficacy of future gene therapies.

1016 Single-Cell Transcriptional Analysis of Human *In Vitro* Platforms to Study Genome Editing Effects in Retinal Tissues

Junha Shin, Katherine P. Mueller, Elizabeth Capowski, Saptarshi Pyne, Sunnie G. McCalla, Shivani Saxena, Kayvan Samimi, Emma Nelson, Maria A. Fernandez, Melissa Skala, David Gamm, Krishanu Saha, Sushmita Roy

University of Wisconsin-Madison, Madison, WI

Human stem-cell-derived retinal organoids offer powerful platforms for studying molecular programs associated with normal and disrupted eye function as well as for rapid assessment of potential targets of genome editing. The efficiency of genome editing in traditional 3D organoid systems is limited because of the low rate of transduction with non-AAV based delivery platforms. We observe that this transduction efficiency could be enhanced by removing the extracellular barriers for viral vector delivery via organoid dissociation and replating the cells into a 2D culture for transduction. However, it is unclear whether 2D platforms faithfully capture the cell type composition and gene expression programs of 3D organoids. To compare the transcriptome states of cells in 2D dissociated cultures and 3D organoids, we performed single cell RNA sequencing (scRNA-seq) of the two different platforms by taking samples from six different time points corresponding to different stages of retinal cell fate specification. To enable integrative analysis of this complex multi-sample dataset, we developed and applied a novel multi-task matrix factorization method named Tree-guided non-negative Matrix Factorization (TMF), which performs sample-specific dimensionality reduction while incorporating the relatedness of the samples. TMF identified cell clusters that were enriched in different retinal cell types. Both 2D and 3D platforms show the presence of a diverse set of cell types including Müller glia, photoreceptors, and horizontal cells. We identified a total of 22.4% of cells from 2D cultures as photoreceptors compared to 51.2% of cells from the 3D organoid cultures, while 2D cultures had a higher proportion of RPE/progenitor cell types compared to 3D cultures. Photoreceptors identified in either platform show expression of known cone and rod marker genes, which validate the identity of these cell types. The photoreceptor cells maintain functionality, as they maintain visual cycle function after delivery of the genome editor. Additionally, we compared transcriptional profiles of transduced cells with that of untransduced cells. In total, 42% of 2D cells were transduced, of which 8% comprised photoreceptors. Overall, this work shows that 2D platforms retain a sizable photoreceptor population which can be efficiently transduced, making them an effective platform for examining molecular signatures of genome-editing in a higher throughput manner.

1017 *In Vivo* Delivery of Genetic Payloads to Human Hematopoietic Stem/Progenitor Cells

Vladimir V. Botchkarev, Sean C. Harrington, Alexander Justen, Casey Kimber, Anjali Kapuria, Suvi Jain, Gonzalo Zeballos, Funmi Adewale, Kelsey Haugh, Samantha Crocker, Anna Liang, Shannon Joyce, Benjamin Ferland, Sundeep Chandra, Kathy Daniels, Matteo Stoppato, Kyle Trudeau, Edward Rebar, Jagesh Shah, Luca Biasco

Sana Biotechnology, Cambridge, MA

Achieving in vivo genetic engineering of hematopoietic stem/progenitor cells (HSPC) would dramatically expand patients' access to gene therapy. However, preclinical development is complicated by the fact that mouse hematopoiesis differs from human and it is not permissive to all human-compatible vector pseudotypes. We have developed a strategy to assess in vitro and in vivo access to human HSPC and achieved efficient in vivo genetic engineering of naïve human HSPC using lentiviral (LV) using BaEVTR and retargeted fusogens. We initially conducted a high-resolution characterization of access to unstimulated HSPCs and resting individual HSPC subtypes in vitro and observed superior BaEVTR targeting of HSPC (~100% at MOI 66, with Vectofusin-1) compared with VSV-G (40% at MOI 50,750), as well as ~20% transduction with BaEVTR LV of resting FACS-sorted hematopoietic stem cells (HSC) at MOI 2, a dose approaching in vivo scenarios. We then set to establish basal access to human HSPC in the bone marrow (BM) and peripheral blood (PB) without relying

on high vector doses or selective enrichment. First, we injected intravenously (IV) BaEVTR and VSV-G LV in long-term humanized mice and showed that 1 low dose BaEVTR LV could transduce 2-4% BM multipotent progenitors vs no detectable transduction in that population using same doses of a VSV-G LV. Because stably humanized mice host skewed human HSPC composition, we characterized early human engraftment and injected LV at D7 of humanization, a timepoint at which we established that human cells are localized only in the BM and the HSPC composition still mirrors the infusion composition, thus providing a unique system to isolate and study in vivo BM access to human HSPC. Mobilization (G-CSF/AMD3100) at this early stage of humanization did not result in substantial egress of human HSPC into the PB but, intriguingly, unlocked transduction to naïve HSC in the BM allowing ~2% targeting of phenotypic HSC with BaEVTR LV compared to undetectable transduction without mobilization. To conversely isolate and study basal PB access to HSPC, we infused mobilized CD34+ cells into NBSGW mice immediately followed by IV injection of LV. In this setting, 1 low dose BaEVTR LV reached 23% transduction of Lin-CD34+ cells and 12% of phenotypic HSC measured at D12 in the BM. This resulted in a 21-23% GFP+ human PB myeloid output over the first 6wks after infusion, stabilizing at 3-7% by wk9. The mice were later mobilized at 11wks and injected with another set of LV carrying the RFP reporter gene to measure stability and plasticity of engineered engrafted HSC as well as susceptibility to multiple transductions. Together the BM and PB access models provide a system to quantitatively assess in vivo delivery to HSPC. In considering bioavailability in the presence of other cellular "sinks," we tested BaEVTR LV transduction of primary human hepatocytes and observed that BaEVTR shows substantially lower gene transfer rates when compared to VSV-G, suggesting a potential evasion of the liver upon in vivo delivery in humans. To reduce off-target delivery, at SANA we are developing retargeted fusogens that are engineered to recognize receptors on chosen target cell types resulting in highly cell-specific in vivo gene transfer. We evaluated retargeted fusogen LV via IV injection and showed a striking 100x specificity increase over other broadly tropic pseudotyped LV in targeting a receptor-positive population exclusively localized in the BM, which make up as little as 0.15% of total human cells. Overall, we generated a robust strategy for establishing basal access and achieving efficient specific in vivo delivery of genetic payloads to human HSPC.

1018 Evaluating the Potential of CRISPR Activation Therapy to Increase *TCF4* Expression in Pitt-Hopkins Syndrome

Renee Napoliello[1], Katherine L. Lucot[2], Julian Halmai[3], Omri Goldenthal[4], Gad David Vatine[5], Kyle D. Fink[3]

[1]Neurology, University of California, Davis, Institute for Regenerative Cures, Davis, CA,[2]UC Davis School of Medicine, Sacramento, CA,[3]UC Davis, Sacramento, CA,[4]Zlowtoski Center for Neuroscience, Ben-Gurion University of the Negev, Beer Sheva, Israel,[5]Ben Gurion University, Beer Sheva, Israel

Pitt-Hopkins Syndrome (PTHS) is characterized by severe intellectual disability and tendency for epilepsy and/or hypotonia. There is currently no treatment for PTHS. PTHS is caused by *de novo* mutations in *Transcription Factor 4* (*TCF4)* which typically result in haploinsufficient expression. *TCF4*, which codes for a basic helix-loop-helix transcription factor, exhibits high expression in the central nervous system. *TCF4* appears to be critical for neuronal development and neuronal function. Cre-induced knockout of *TCF4* in adult mice altered firing patterns and dendritic structure in excitatory neurons, and induced memory deficits. However, the effects of PTHS may be ameliorated by restoring *TCF4* expression. Cre-induced knockout of a STOP cassette in the Tcf4 gene in mice, to reinstate Tcf4 expression in a PTHS model, improved activity levels, memory, and innate behaviors such as nest building. *TCF4* expression reinstatement also normalized EEG abnormalities and expression of key *TCF4*-regulated genes related to neuronal maintenance. It is thus plausible that rescue of standard *TCF4* expression could be beneficial. CRISPR activation (CRISPRa) is a valuable avenue of expression rescue by targeting the wild-type promoter of *TCF4* for activation. CRISPRa is comprised of a guide RNA (gRNA) to target the promoter of the gene, a deactivated Cas9 (dCas9), and tethered transcriptional activators. We evaluated gRNAs for human *TCF4* to design a CRISPRa system.**Methods**: 23 gRNAs designed for the human genome were screened in HEK293T-LentiX cells. Of the guides, nine were designed from a dataset based on a predictive algorithm and 14 were designed from the ChopChop software. The gRNAs were cloned into a codon optimized gRNA expression plasmid. The gRNA plasmid was co-transfected with two other plasmids containing one half each of the dCas9-VPR-MPH complex, separated by an intein sequence. After analysis, a set of candidate lead gRNAs was selected and the same transfection method was performed on two independent iPSC-derived neuronal stem cell (NSCs) lines. In addition, patient (*TCF4* KO) iPSCs and same-sex parental control iPSCs were differentiated into NSCs, for lead gRNA evaluation.**Results:** From the HEK293T transfection (for human guides) five gRNAs exhibited significant upregulation of *TCF4* transcript expression. The lead guide was chosen as the guide with the greatest expression fold change from the transfection of the five guides in the healthy and patient NSCs. **Conclusion:** CRISPRa is able to significantly upregulate *TCF4* across multiple cell lines. CRISPRa will be tested in multiple PTHS cell lines to evaluate functional rescue. As transduction can be a more efficient method of therapy delivery compared to transfection, transduction experiments with the lead guide will be performed.

1019 High-Throughput Functional-Based Screening of Chimeric Antigen Receptor (CAR)-T Cells Using Nanovial Technology

Wei-Ying Kuo, Jesse Liang, Lucienne Bosler, Neha Iyer, Sean Padgett, Dino Di Carlo, Joseph de Rutte

Partillion Bioscience, Los Angeles, CA

We present a workflow that leverages flow cytometry and cavity-containing hydrogel microparticles to enrich antigen specific chimeric antigen receptor (CAR)-T cells and sort functionally active populations in high-throughput based on cytokine secretion. CARs are synthetic immune receptors that repurpose natural signaling components to redirect T cells to selectively eradicate cancers but have shown limitations including toxicities, in vivo persistence, and tumor relapse. In addition, the limited success of the CAR-T approach in solid tumors has been generally attributed to a hostile tumor microenvironment (TME). Sub-optimal design of current CAR constructs also plays a key role. The lack of an efficient and accessible functional-based method for interrogating CAR-T cells impedes the development of T-cell-based immunotherapies. To address this gap, we developed an

approach to screen millions of functionally active CAR-T cells using cavity-containing hydrogel microparticles (Nanovials). Nanovials act as suspendable sub-nanoliter containers for individual cells that can be modified to perform biological assays. Here we modified nanovials with a model antigen (CD19) to enrich and bind individual antigen-specific CAR-T cells into the cavity of the nanovials. Nanovials are modified with antibodies against target cytokines to capture secreted cytokines (IFN-gamma, IL2, TNF-alpha) from activated CAR-T cells. Captured cytokines stained with fluorescent secondary antibodies to identify secreting cell populations and nanovials containing functionally active CAR-T cells are then analyzed and sorted using standard commercially available flow cytometers. Cells isolated after flow can then be expanded for further studies or sequenced to recover transcript information. Using this workflow, we quantified the amount of cytokine secreting CAR-T cells across different patient samples and correlated cytokine secretion levels to differences in CAR engineering. Furthermore, we identified and isolated significantly different subpopulations of CAR-T cells within a patient sample on the basis of cytokine secretion. The capability to resolve and isolate subpopulations within a single patient sample is made possible through the single cell resolution enabled by our platform and is not possible through current bulk analyses techniques such as ELISA, or other advanced technological readouts like impedance based cell-killing assays.In summary, we present a flow cytometry approach to screen CAR-T cells based on antigen specificity and cytokine secretion using our nanovial platform. This readily adoptable platform can provide researchers with improved tools for screening CAR designs at scale and can be used to improve current quality control workflows used in cell therapeutic manufacturing.

1020 rAAV Gene Therapy for Fabry Disease: Enhanced Secretion of α-GLA by Signal Peptide Engineering

Biao Dong

Sichuan University, Chengdu, China

Fabry disease is an X-linked lysosomal storage disease due to a deficiency of α-galactosidase A (α-Gla A) with the prevalence of approximately 1 in 40,000.There are two clinical subtypes of Fabry disease, classic (type I) and late-onset (type II), depending on the level of enzyme function in patients. A typical characteristics of this disease is the progressive and systemic accumulation of sphingolipids such as globotriaosylceramide (Gb3) and its derivative, globotriaosylsphingosine (lyso-Gb3), in the lysosomes of vascular endothelial cells. The standard treatment for patients is enzyme replacement therapy which is a lifelong burden and a considerable proportion of type I males eventually produce neutralizing antibodies. The overexpression of α-Gla A in the liver by rAAV gene therapy is believed to be a longer lasting and effective treatment. Thus, we hypothesized that the use of an α-Gla A gene with enhanced secretion capacity compared to the wild type may have better treatment efficiency. To this end, the signal peptide of α-Gla was replaced by 22 heterogenous ones and the constructed plasmids were used to transfect HepG2 cells individually. The supernatants were collected and used for ELISA and enzymatic assays. During the screening, four signal peptides were found to have 1.5-3 folds higher expression levels and enzyme activities than the wild type. sp21 was further evaluated in vivo using Fabry mice. A codon optimized α-Gla A with the sp21 peptide under the control of a novel liver specific promoter were packaged in a self-complementary rAAV vector with serotype AAV8. Two doses of the vector, $2x10^{12}$ and $5x10^{12}$ vg/kg, were administrated by tail vein injections. α-Gla A activity levels were measured in plasma sampled at 0, 2, 4, 6, and 8 weeks. Expression levels were stable since week 2 with activities as high as 1678 nmol/h/mL. Mice were sacrificed at 6 and 14 weeks to quantify lyso-Gb3 level in plasma by LC-MS/MS. We demonstrated that the lyso-Gb3 was largely cleared in the plasma and the amounts were less than 1%. It was also demonstrated by IHC that the expression levels of α-Gla A in the liver, heart, spleen, and kidney at week 14 were significantly higher than the negative control.

1021 Next-Generation of AAV Gene Therapy for Spinal Muscular Atrophy

Chunjuan Song, Qingzeng Wang, Qian Lu, Zhongwan Li, Zhucheng Lin, Ying Zhou, Shuyuan Chen, Lijun Wang, Guo-Jie Ye, Zhenhua Wu

Exegenesis Bio Inc., Lower Gwynedd, PA

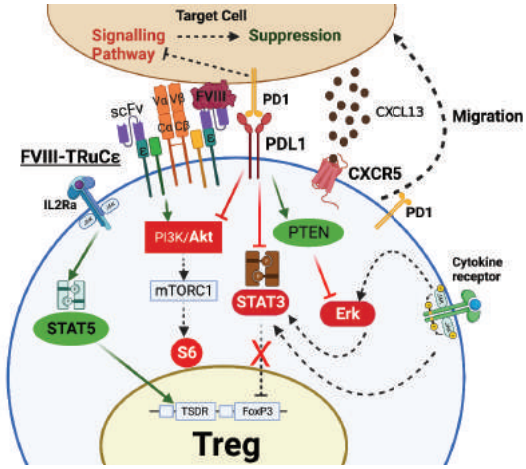
Spinal muscular atrophy (SMA) is an autosomal recessive neurodegenerative disorder caused by a mutation in the survival motor neuron 1 (*SMN1*) gene, which leads to progressive muscular weakness and hypotonia as a consequence of the loss of α motor neurons of the spinal cord anterior horn. Gene therapy has been successfully developed for SMA and the commercialized medicine Onasemnogene abeparvovec (Zolgensma), was approved by FDA in 2019 as a one-time intravenous (IV) administration to SMA patients below the age of 2 years, which demonstrated significant clinical benefits including prolonged survival and motor milestone achievement. However, current gene therapy faces various challenges including insufficient expression of the *SMN1* gene in the target organs/tissues and off-target toxicity such as liver failure. Thus, there is a need for improved gene therapies for SMA with tissue specific SMN expression and reduced off-target toxicity. Our first-generation product of AAV-based gene therapy (EXG001-307K) had demonstrated a better extended survival, greater motor improvement and significantly reduced toxicity in the mouse model of SMA and a very promising profile in our clinical trials. To further enhance the efficacy and safety, we are designing the second-generation gene therapy product including AAV novel constructs with optimized transgenes and new route of administration (ROA). Codon optimized transgenes, secreted forms and stabilizing mutants of human *SMN1* (*hSMN1*) have been extensively studied both *in vitro* and *in vivo*, including the comparison of protein expression level, potency, secreting pathway, and efficacy. Significantly higher protein expression level has been achieved from the novel transgenes compared to the natural sequence of *hSMN1*, and a subset of the candidates showed a better survival rate and behavior improvement than the first-generation product EXG001-307K. In addition, we have also examined direct intra-CSF administration (new ROA) of EXG001-307K in SMNΔ7 mouse model, which revealed higher AAV genome biodistribution and protein expression in the central nervous system (CNS) and a lower distribution and protein expression in the peripheral organs (liver and heart) thus a better profile of efficacy and safety (lower off-targeting) than the same dose when administered by IV. Transduction efficiency and dose escalation have also been assessed and compared in mouse and nonhuman primates (NHPs) to assure a feasible and efficacious dose range for the translational work towards clinical application.

1022 PDL1 and CXCR5 Modified FVIII Specific TRuCε Tregs Exhibit Enhanced Trafficking and Suppression of Anti-Drug Antibody Formation

Jyoti Rana[1], Maite Munoz-Melero[1], Anja Schmidt[2], Christoph Königs[2], Janine Becker-Gotot[3], Moanaro Biswas[1]

[1]IUPUI, Indianapolis, IN,[2]Goethe University, Frankfurt, Germany,[3]Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany

Anti-drug antibodies (ADA) can develop against therapeutic biologics, reducing treatment efficacy and leading to unwanted side effects. In hemophilia A (HA), which is an X-linked blood clotting disorder caused by mutations in the factor VIII (FVIII) gene, replacement protein therapy with recombinant FVIII is significantly complicated by ADA formation. Previously, we established that cellular therapy with engineered FVIII specific T cell receptor fusion construct (TRuC) regulatory T cells (Tregs) delivers specific and durable suppression of ADA responses in a preclinical HA model [Mol Ther 2021, 29:2660-2676]. Here, we engineered FVIII TRuCε Tregs to co-express the programmed death 1 ligand 1 (PDL1) checkpoint inhibitor or the chemokine receptor CXCR5, with the aim to improve suppressive capacity, phenotypic stability, and in vivo localization to germinal centers, which are the site of ADA development. First, we validated a role for PDL1 in ADA tolerance by showing that 2 intraperitoneal injections of non-lytic mouse PD-L1Fc (100 µg/mouse) administered 1 day prior to FVIII weekly injections (1.5 IU/week for 4 weeks) caused HA mice to develop 3-fold lower ADA titers (5.16±4.7 BU/mL) compared to mock treated animals (18.15±6 BU/mL). In vitro, we confirmed that FVIII TRuCε-PDL1 and FVIII TRuCε-CXCR5 expressing murine Tregs responded specifically to FVIII stimulation by upregulating CD69, PD1, ICOS, CTLA4 and LAP. PDL1 signaling significantly downregulated phosphorylation of STAT3, Akt (S467), S6 and Erk, whereas STAT5 phosphorylation in response to FVIII stimulation was unaffected. Therefore, PDL1 acts at the level of PI3K/Akt, RAS/MAPK and STAT3 signaling to conserve the immunosuppressive phenotype of FVIII TRuCε-PDL1 cells via a process of suppressive "back-signaling" (**Figure**). Next, we confirmed enhanced chemotaxis of FVIII TRuCε-CXCR5 Tregs towards a CXCL13 gradient, which was generated across a transwell in vitro or by continuous FVIII injections in vivo. Finally, adoptive transfer of 5 x 10^5 FVIII TRuCε-PDL1 or FVIII TRuCε-CXCR5 Tregs was able to control ADA formation in response to weekly FVIII injections in HA mice. 8 weeks following adoptive transfer, control mice that received only FVIII injections developed high titer ADAs of 14.36 ± 5.536 BU/ml. FVIII TRuCε-PDL1 and TRuCε-CXCR5 Treg recipient animals had significantly lower ADA titers of 2.501 ± 1.081 BU/ml (p=0.003) and 1.963 ± 0.7442 BU/ml (p=0.0169), respectively. Suppression was maintained for up to 12 weeks in the FVIII TRuCε-PDL1 recipient group as compared to the FVIII control group (7.702 ± 2.185 vs 34.32 ± 9.052 BU/ml, p=0.023), demonstrating that co-expression of PDL1 prolongs the effectiveness of engineered Treg therapy. This study shows that the PDL1/PD1 axis is important for promoting the suppressive capacity of FVIII TRuCε Tregs, whereas expression of CXCR5 improves recruitment of engineered T cells to sites of immune response initiation. We are currently evaluating the efficacy of a combined FVIII TRuCε-PDL1-CXCR5 receptor construct and defining the immune mechanisms underlying its enhanced suppressive capacity.



1023 ADI-270: An Armored Allogeneic "Off-the-Shelf" CAR γδ T Cell Therapy Targeting CD70+ Cancers

Gauri Lamture, Alexander G. Teague, Morgan Smith-Boeck, Michael Salum, Ramandeep Kaur, Smitha Rao Yelaguli Gundurao, Pannaga Parthasarathy, Amy Doan, Jyothi Sethuraman, Ngoc Hoang, Hayden Tessman, Philip Storm, Soojin Han, Swapna Panuganti, Chris Rold, Yvan Chanthery, Marissa Herrman, Blake T. Aftab, Arun Bhat, Kevin P. Nishimoto

Adicet Bio Inc., Redwood City, CA

Background: CD70 represents a compelling target for the development of CAR T cell therapies due to its high expression in multiple solid and hematological malignancies. CAR T efficacy in solid tumors has been a key challenge in the field and emerging strategies to improve clinical responses is to employ alternative cytotoxic effector cells with multifunctional tumoricidal activity. γδ T cells combine innate and adaptive immunity to kill malignant cells, and their infiltration into various cancers, including those expressing CD70, significantly correlates with survival. Strategies targeting CD70 by engineering its natural receptor (CD27) as the antigen-recognition moiety of a CAR have demonstrated superior preclinical antitumor activity compared to scFv-based approaches. Additional armoring of CAR-T cells to mitigate the immunosuppressive tumor microenvironment can further enhance activity. Here we report the manufacturability and functionality of ADI-270, a γδ T cell product expressing CD27 natural receptor CAR armored with a dominant negative TGFβRII, for targeting CD70+ cancers. **Methods:** Qualified donor PBMCs were used to activate, expand, and engineer Vδ1 T cells to express CD70 CAR in an established manufacturing process. *In vitro* phenotype, cytokine profile, and antitumor functionality of ADI-270 were determined using flow cytometry, multiplex cytokine assays, and cell-based cytotoxicity assays against cell lines having a wide range of CD70 expression. Human tumor xenograft models in immunodeficient mice were used to evaluate *in vivo* efficacy after a single dose of ADI-270. In addition, *ex vivo* analysis was performed to evaluate the proliferation and phenotype of ADI-270 cells in the tumor and non-tumor tissues. **Results:** Vδ1 T cells modified to express CD70 CAR were successfully generated and expanded, indicating product expansion was not hindered by putative

risks for CD70-mediated fratricide in the manufacturing process. The resulting ADI-270 Vδ1 CAR T cells expressed a predominant naïve-like memory phenotype with potent *in vitro* cytotoxicity and production of proinflammatory cytokines against CD70+ tumor cell lines. Lastly, ADI-270 significantly inhibited tumor growth *in vivo* and proliferated specifically in tumors. **Conclusion:** In summary, ADI-270 demonstrates preclinical proof-of-concept of an armored allogeneic CD70 γδ CAR T cell therapy utilizing the CD27 natural receptor CAR format for targeting CD70^{+} cancers. These data support continued development and further investigation of ADI-270 in the clinic.

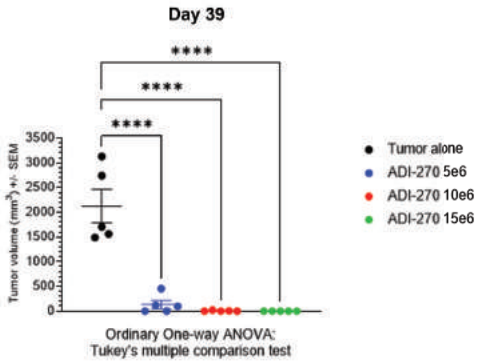


Figure 1: In vivo efficacy of ADI-270 in a subcutaneous A498 tumor model in NSG mice

1024 Liver Fibrosis Alters AAV Biodistribution and Impairs Hepatocyte Transduction

Gemma Bruno, Rosa Ferriero, Edoardo Nusco, Pasquale Piccolo

Telethon Institute of Genetics and Medicine (TIGEM), Pozzuoli, Italy

Adeno-associated viral vectors (AAVs) are the most promising tools for liver-directed gene therapy. However, integrity of hepatic architecture has been considered pre-requisite for efficient gene delivery and patients with hepatic damage and fibrosis are currently excluded from clinical trials. However, AAV-mediated gene transfer to fibrotic livers has been poorly investigated so far. In the present study, we investigated biodistribution and hepatocyte transduction of AAV8-based vectors, commonly used in liver-directed gene therapy clinical trials, in the context of liver fibrosis. Analysis of three mouse models of induced and genetic liver fibrosis revealed that fibrotic livers were transduced less efficiently by AAV8 and this resulted primarily from reduced vector uptake by the liver, rather than from vector genome loss due to hepatocyte proliferation. Moreover, liver fibrosis altered vector blood clearance and biodistribution in extrahepatic organs, significantly increasing viral particle uptake by spleen and kidney. AAV immune profile and distribution in liver and spleen at the cell-type level in fibrotic animals are currently under investigation. Overall, these findings demonstrate that liver fibrosis impairs AAV-mediated gene transfer to hepatocytes and highlight the relevance of the limitations posed by liver fibrosis to efficient and safe gene transfer.

1025 AAV-CRISPR/Cas9 Mediated Gene Editing in Patient *RPGR* hiPSC-Derived Retinal Organoids

Andrew McDonald, Thanh Nguyen, Camiel Boon, Jan Wijnholds

Department of Ophthalmology, Leiden University Medical Centre, Leiden, Netherlands

Background: Mutations in the *RPGR* gene are the predominant cause of X-linked retinitis pigmentosa (XLRP). An inherited retinal dystrophy with a progressive loss of photoreceptors leading to eventual blindness. Notably, RPGR has two primary protein isoforms, the constitutive RPGR$^{1\text{-}19}$ protein translated from 19 exons expressed in most tissues, and the retinal specific RPGR^{ORF15} protein translated from the first 14 exons plus a final exon 15 and part of intron 15 (ORF15). The *RPGR* ORF15 isoform is differentially spliced to terminate in intron 15, a highly repetitive region and known mutational hotspot. The exact function of RPGR^{ORF15} in the retina has not been fully elucidated, but it is known to localise in the transition zone of the photoreceptor cilium and presumably plays a role in protein trafficking and outer-segment maintenance. **Results:** iPS cells were generated from *RPGR* patient skin fibroblasts (c.706>T p.Gln236* and c.425T>G p.Ile142Ser) with nonsense or missense mutations, respectively. Corresponding isogenic controls were generated by CRISPR/Cas9. The *RPGR* and isogenic control hiPSC were validated by sequencing whereas absence of genomic instability was checked by copy number variation tests and karyotyping. In order to effectively model *RPGR* XLRP, the *RPGR* patient hiPSC lines and their isogenic controls were differentiated into retinal organoids. Retinal organoids were cultured up to differentiation day 240 and characterised by immunohistochemistry, examining phenotypic variations in photoreceptor and cilial morphology. Additionally, functional RPGR^{ORF15} is post-translationally modified in the highly-repetitive C-terminal region by glutamylation. Upon differentiation to retinal organoids, both patient lines exhibited a loss of glutamylated RPGR^{ORF15} as determined by Western blot. Currently there is no known cure for *RPGR* XLRP, although progress has been made with AAV delivered gene augmentation strategies. As an alternative approach, we have pursued the development of a broadly applicable AAV-CRISPR/Cas9 mediated gene editing strategy. The post-mitotic nature of the retina necessitates a gene editing strategy that does not utilise homology directed repair, as this pathway is not active in non-dividing cells such as photoreceptors. Here, we use a homology-independent targeted integration (HITI) based strategy to insert a codon optimised super-exon, including exons 2-ORF15 of *RPGR* with a C-terminal self-cleaving EGFP reporter (4.4 kb). By targeting intron 1 of *RPGR* we are able to replace 99.9% of the coding sequence of the *RPGR* gene whilst retaining the endogenous promoter. The feasibility of this gene editing strategy has been demonstrated in HEK 293T cells, with 5' and 3' junction PCR confirming desired integration of the donor sequence in the *RPGR* intron 1 locus. As of yet, we are still to quantify the efficiency and precision of this strategy in hiPSC-derived retinal organoids. **Summary/Discussion:** We successfully generated patient *RPGR* hiPS cells and their isogenic controls. We differentiated these hiPSC into retinal organoids, and at first glance there are no major histological differences between *RPGR* mutant and wild-type retinal organoids. We aim to deliver a CRISPR/Cas9 system to retinal organoids via dual

AAVs, with one AAV containing the gene editing machinery (SaCas9 and sgRNA), and the other delivering the 4.4 kb donor sequence. Upon successful gene editing in retinal organoids we will determine the correct expression, localisation and post-translational modification of RPGR.

1026 Development of an alpha-Synuclein Targeting Vectorized Antibody Strategy: First *In Vivo* Proof of Mechanism in Wild Type Mice

Seya Acar-Broekmans, Rhode Erbrink, Charlot Van Rooijen, Lukas K. Schwarz, Meriem Bourajjaj, Laura Tadè, Verena Hehle, Astrid Vallès

uniQure Biopharma BV, Amsterdam, Netherlands

Synucleinopathies are neurodegenerative disorders characterized by aggregation of alpha-synuclein protein (α-Syn), encoded by the SNCA (Synuclein Alpha) gene. Alpha-synuclein is expressed in the brain and also peripherally in red blood cells. In the brain, in the context of neurodegenerative disease, α-Syn can form aggregates, which in turn may spread in a prion-like manner, with toxic aggregated forms being transmitted from cell-to-cell as the disease progresses. In this regard, facilitating the clearance of α-Syn aggregates outside of the cell may have therapeutic potential by reducing the spread and potentially slowing or even halting disease progression. Hence, passive immunization with α-Syn-targeting antibodies is in focus of many ongoing preclinical and clinical studies. The main challenge of administering α-Syn antibodies peripherally is for them to pass through the blood-brain barrier to perform their function. Additionally, α-Syn antibodies will bind to α-Syn that is abundant in the blood resulting in a sudden decrease in their bioavailability. Lastly, repeated antibody injections will be needed for a sustainable antibody therapy, which can lead to anti-drug antibody formation. We are developing specific α-Syn vectorized antibodies, using our AbQURE™ technology platform, to provide a stable supply of α-Syn antibodies in the brain. Full length α-Syn antibodies AbQURE-1 and AbQURE-2, both targeting the C-terminal part of α-Syn, were successfully expressed in our AbQURE™ platform, both from a plasmid and from an AAV (AAV-AbQURE-1 and AAV-AbQURE-2). We established proof of mechanism (PoM) in wild type mice after direct brain administration of the vectorized antibodies. In this study, we showed a dose-dependent expression of the antibodies in the brain, using both biochemical and histological methods. Detection of antibodies with in-house developed MSD assays showed functional vectorized antibody expression in the striatum. This was confirmed by immunohistochemical methods in relevant tissue sections. No safety concerns were reported in the pathological examination of the Hematoxylin and Eosin (H&E) staining of the treatment groups compared to the negative control group. Present data demonstrates a safe and efficacious expression of specific α-Syn antibodies using our proprietary AbQURE™ platform. As a follow up, efficacy of anti-α-Syn antibodies to reduce the α-Syn spreading will be evaluated in relevant disease models in the context of therapeutic application to synucleinopathies. *AbQURE is a trademark registered in the European Union and United Kingdom and pending in other jurisdictions.*

1027 Establishment of a Clonal, Serum-Free, Suspension-Adapted HEK293 Cell Line for the Manufacturing of Adeno-Associated Virus Vectors

Marguerite Campbell[1], Kelly Geosits[1], Matthew Ercolino[2], Thomas J. Burton[2], Ngan Trinh[1], Khan Umaer[1], Srivanya Tummala[1], Amy Sacks[2], Brian Tomkowicz[1]

[1]Viral Vector Research & Development, Center for Breakthrough Medicines, King Of Prussia, PA,[2]Process Development, Center for Breakthrough Medicines, King Of Prussia, PA

Adeno-associated virus (AAV) is an effective viral vector for gene therapy due to several factors: infection of post-mitotic cells, non-pathogenic, broad tissue specificity coupled with efficient cellular transduction, and durable transgene expression. As AAV-based gene therapies are becoming increasingly more prevalent, a renewed emphasis on scalable manufacturing platforms efficient in generating high yields of, highly pure, and potent quantities of viral vectors is paramount to success. Moreover, these scalable processes should focus on the overall reduction in costs-of-goods to make these complex therapies self-sustaining and accessible to all. Utilizing the well-established, adherent, Frank Graham HEK293 cell line as a starting point, we have successfully adapted cells from a qualified master cell bank to grow in animal component-free, suspension conditions, in shake flasks and bioreactors. In head-to-head studies comparing our CBM-HEK suspension-adapted versus 3 commercially available suspension HEK293 cell lines, we demonstrate similar, if not better, yields of AAV vectors, following plasmid triple transfection method for virus production. To achieve this, we focused specifically on a number of parameters to optimize such as media selection, transfection reagent optimization, transfection parameters and cell density. In order to establish a cell line amenable for use in GMP-grade manufacturing, we clonally printed CBM-HEK293 pool cells using the Cytena f.sight cell printing and CloneSelect imaging platform. Herein, we show full-traceability of clonal outgrowth from single-cell through scale-up and have identified select clones that perform equally well in head-to-head comparison studies versus other HEK293 cell lines for virus production. Moreover, these CBM-HEK293 clones can support the production across a diverse panel of all natural AAV serotypes. We are currently establishing a GMP master cell banks for use in large scale AAV manufacturing.

1028 Highly Specific Interaction of Exosomes with Long-Term Hematopoietic Stem Cells

Sanam Rezaei Benam[1], Alexander Robert Maldeney[2], Kinjal Bhadresha[1], Reza Shahbazi[1]

[1]Department of Medicine, Indiana University School of Medicine, Indianapolis, IN,[2]Department of Microbiology and Immunology, Indiana University School of Medicine, Indianapolis, IN

Long-term hematopoietic stem cells (LT-HSCs) have been of high interest due to their exceptional self-renewal potential, persistence, and capability to repopulate all blood cell populations. This is very important in terms of bone marrow transplantation, and gene therapy/gene editing approach where transplanting a sufficient number of LT-HSCs or therapeutic gene modification in these cells can guarantee the

success of treatment. LT-HSCs are a rare population of hematopoietic stem and progenitor cells (HSPCs). Generally, HSPCs are identified with CD34 surface marker and contain multiple other populations such as long-term hematopoietic stem cells (LT-HSCs), multipotent progenitors (MPPs), and common myeloid progenitors/granulocyte-monocyte progenitors/megakaryocyte-erythroid progenitors (CMP/GMP/MEP) that all require a long list of surface markers for hierarchical organization. Previously it was shown that a panel of 5 antibodies targeting surface markers on HSPCs could differentiate LT-HSCs ($CD34^+$, $CD38^{-/low}$, $CD90^+$, $CD45RA^-$, $CD49f^+$) from other lineages [1]. However, to date, there has not been any report on a single molecule capable of identifying LT-HSCs. Our recent data show that using small nanovesicles (30-100 nm) called exosomes we can achieve almost 80% targeting of LT-HSCs. We performed large exosome screening from different cancer types and healthy tissues and we identified exosomes that highly interact with LT-HSCs. Especially cancers with bone metastatic profiles had higher LT-HSC interaction. A perfect example of this was prostate cancer exosomes from two different PC3 (low bone metastasis profile) and C4-2B (high bone metastasis profile) cell lines in comparison to normal human primary prostate epithelial cells (HPrEC). We saw five times more interaction of C4-2B exosomes with LT-HSCs (78.7%) in comparison to PC3 exosomes (16.2%) and HPrEC exosomes (3.6%). We achieved the same results for the H929 cell line which is a representative cell line for multiple myeloma. However, for ANBL6, which is another model cell line of multiple myeloma we did not see any significant interaction. This highly specific exosomal interaction in multiple myeloma could be related to lytic bone damage in this cancer type, where exosomal interaction with LT-HSCs might drive the osteoclast/osteoblast imbalance leading to lytic bone damage. Another important result of our study was discovering the highly specific interaction of normal human primary small airway epithelial Cells (HSAEC) with LT-HSCs. This specific interaction is happening with exosomes derived from healthy lung cells and shows the ongoing exosomal communication between lung tissue and LT-HSCs. It was previously reported that the lung contains hematopoietic progenitor populations however, this is the first time we report highly specific exosomal interaction between the lung and LT-HSC population. Following 48 h interaction of lung exosomes with CD34 cells we observed high colony-forming potential and higher CFU-GEMM colony formation. Currently, we are continuing our studies by understanding the relationship between bone metastasis and exosomal interaction with LT-HSCs. Also, we are doing in vivo studies to understand exosomal communication between lung exosomes and LT-HSCs. Our findings show a network of communications that both cancer cells and healthy cells use to modulate hematopoiesis and potentially promote metastasis in cancer.

1030 A Gene-Independent Treatment Strategy for Inherited Retinal Diseases Using Cas9-VPR-Mediated Cellular Reprogramming and Neuroprotection

Klara Sonnie Hinrichsmeyer[1,2], Nina Karguth[1], Martin Biel[1], Elvir Becirovic[2]

[1]Department of Pharmacy - Center for Drug Research, LMU Munich, Munich, Germany,[2]Dept. Ophthalmology, University Hospital Zurich, University of Zurich, Zurich, Switzerland

Inherited retinal dystrophies (IRDs) comprise a heterogeneous group of eye diseases which often affect rod photoreceptors and lead to retinal degeneration. Currently, there is no therapy to halt or slow down retinal degeneration for the vast majority of IRD patients. Most studies investigating therapeutic approaches for IRDs take advantage of the classical gene supplementation strategy using adeno-associated viral (AAV) vectors to express an intact copy of the defective gene in target cells. However, this therapy requires a comprehensive preclinical development and clinical trials for every individual gene and is hardly feasible given the large number of IRD-linked genes. Alternatively, inactivation of cell-damaging genes or activation of cell-protective genes could lead to a mutation- and gene-independent therapy approach that prolongs cell survival and could even stop disease progression. Recent approaches have shown that knockout of the *Nrl* gene can ameliorate the retinal phenotype in mouse models carrying mutations in rod-specific genes, by reprogramming rods into cone-like cells. Similarly, other studies have demonstrated that the delivery of one or both of the rod-derived cone viability-factors (RdCVF1 or RdCVF2) encoded by the nucleoredoxin like 1 or 2 gene (*Nxnl1 or Nxnl2*) to photoreceptor cells can improve the retinal phenotype in IRD mouse models. Nevertheless, both gene-independent strategies, while promising on their own, would benefit from an approach that combines their advantages. Here, using a multiplexing gene editing approach, we set out to establish a proof-of-principle for a novel gene-independent retinal gene therapy approach, based on concurrent knockdown of *Nrl* and activation of *Nxnl1* and *Nxnl2* in the retina. For this purpose, we applied dual mRNA trans-splicing AAV8 Y733F vectors (6×10^{11} vg/µl) to subretinally deliver the Cas9-VPR module in wild type animals and in the common mouse model for autosomal dominant retinitis pigmentosa ($Rho^{P23H+/-}$). Cas9-VPR expression was driven by a photoreceptor-specific rhodopsin kinase (GRK1) promoter and combined with sgRNAs of different spacer lengths targeting *Nxnl1*, *Nxnl2* (14 nt each) and *Nrl* (20 nt) to achieve gene activation or knockout, respectively. Four weeks upon subretinal injection, we confirmed *Nrl* knockout, successful reprogramming and activation of *Nxnl1* and *Nxnl2* in the murine retina using western blotting and qRT-PCR experiments. Optical coherence tomography and electroretinography in $Rho^{P23H+/-}$ mice demonstrated improved retinal structure and function up to six months after treatment. Taken together, we provide the first evidence for therapeutic benefit of a novel, gene-independent strategy for IRDs that utilizes concurrent Cas9-VPR-mediated knockout and activation of different genes designed for cellular reprogramming and neuroprotection. Many IRD-patients could profit from such an approach, but similar strategies could also be applied to non-ocular diseases.

1031 Drug Product Development of Adenovirus: Platform Approaches to Select Early Phase Formulation and Fill/Finish Strategy

Conor R. Lake[1], Tatiana Nanda[2], Kayla Sponsel[2], Avi Nandi[2], Amy Sacks[2], Chris Nieder[1], Kevin Schutt[1], Honggeun Park[1], Trey Hanshew[1]

[1]Process Development, Center for Breakthrough Medicines, King of Prussia, PA,[2]Center for Breakthrough Medicines, King of Prussia, PA

The gene therapy is an accelerating development field utilizing many types of viral vectors to deliver the gene of interest. One of these vectors is adenovirus which is typically produced using suspension or adherent upstream process. Both platforms can produce a high titer (>1E12 vp/mL) adenovirus drug substance. Challenges arise when proceeding through the downstream purification steps and into the final drug product process steps. In this study, a high titer adenovirus drug substance was used as the basis for a drug development campaign that encompassed both formulation confirmation and fill/finish development. The target formulation of interest was adapted from previous literature and compared to a base buffer to demonstrate feasibility of meeting target product profile. Here we demonstrate that a specific set of analytical methods targeting physical, colloidal and physical titer attributes is capable to decipher a more optimal formulation with a small material requirement in an expedited manner. Additionally, a fill/finish process was designed using a small-scale V-max study to select appropriately sized and compatible sterile filters. The resulting data from particulates, turbidity, and viral genome titer measurements allowed to minimize product loss due to material adsorption and hold-up volume and prevent a catastrophic event of filter fouling.

1032 Cell Based IL12 Immunomodulation Combined with PD-1 Inhibition Generates Local and Abscopal Immune Activation to Eradicate Metastatic Pancreatic Cancer

Omid Veiseh

Bioengineering, Rice University, Houston, TX

Introduction: Proinflammatory Cytokines have been FDA approved for cancer immunotherapy for treatment of metastatic melanoma and renal carcinoma for over 30 years. To overcome stability and toxicity limitations seen with high dose cytokine immunotherapy, we developed a delivery platform, called cytokine factories, composed of genetically engineered epithelial cells encapsulated in biocompatible polymers. Cytokine factories can safely deliver high local doses of pro-inflammatory cytokines, such as interleukin- 2 (IL2) and 12 (IL12) and allow for controlled and programable dosing *in vivo*. The IL2 producing version of this technology has advanced to human clinical trials for the treatment of ovarian cancer. Here, we highlight our advancements towards further development of this technology to produce IL12 in combination with PD1 check point blockade to treat metastatic pancreatic cancer and metastatic models of melanoma. **Results:** Tumor-adjacent administration of IL12-based cytokine factories *in vivo* created a high local cytokine concentration (IP space) without substantial leakage into the systemic circulation. In addition, administration of cytokine factories in combination with anti-PD1 checkpoint inhibitors caused reduction of tumor burden by over 60% when delivered as a monotherapeutic to mice with metastatic melanoma. Further, when administered in combination with local anti-PD1 checkpoint inhibitors, these cytokine factories led to reduction of intraperitoneal tumor burden by over 80% after only 10 days of treatment. Finally, we evaluated the ability of this therapy to treat pancreatic tumors which are notoriously known to be resistant to immunotherapy. We found that the median survival for control animals was 45 days. However, 8/8 of animals treated with IL12 cytokine factories survived throughout the duration of the study (110 days), demonstrating a significant extension of overall survival time. Finally, the pharmacokinetics, pharmacodynamics and safety of this system were evaluated in non-human primates (NHP). A single administration of led to therapeutic levels of IL-12 in the intraperitoneal cavity in NHP and produced local and systemic T cell biomarker profiles that predict efficacy. In addition, administration of cytokine factories at various doses in NHP were well tolerated with no signs of cytokine storm and vascular leak syndrome with no abnormal clinical observations and no evidence of adverse pathologic effects on local or systemic tissue by all animals during the study. **Conclusions:** Our findings demonstrate efficacy of cytokine factories as single agent and combination therapeutics in preclinical animal models and provide rationale for future clinical testing for the treatment of metastatic peritoneal cancers in humans.

1033 MRI Guided Delivery to the Putamen Using the Northern Arc: A Custom Frame Allowing Occipital Approaches in Large Animal Models

Christen Simon-Anderson[1], Andy Carlson[1], Eva Wembacher[2], Mark Johnson[1]

[1]Northern Biomedical Research, Norton Shores, MI,[2]Brainlab AG, Munich, Germany

Introduction: Delivery of gene therapies directly to the central nervous system allows the blood brain barrier to be bypassed and decreases the risk for systemic exposure and toxicity. Intraparenchymal (IP) delivery directly to the brain using Convection Enhanced Delivery (CED) is ideal for maximizing exposure of the target of interest (e.g., putamen, caudate, substantia nigra) to the therapeutic agent. Currently, multiple targeting devices are used for CED in the human patient. However, application of devices scaled for a human can be challenging to apply to a large animal laboratory species. Northern Biomedical Research (NBR) has developed a custom Magnetic Resonance (MR) compatible system (the Northern ARC) to allow bilateral infusion device placement and for simultaneous, real-time MRI guided CED. The frame allows a full range of targeting, from anterior/frontal to occipital approaches. The objective of this study was to assess feasibility and effectiveness of the Northern ARC for infusions into the putamen using occipital trajectories. **Methods:** Three cynomolgus macaques were anesthetized and placed in a semi-prone position in the Northern ARC frame. Bilateral craniotomies were made for an occipital approach to the putamen and the animals were transferred to the MRI (Philips Achieva 3.0T). The putamen was targeted using gadolinium-filled arrays (2 mM ProHance, Bracco) attached to the frame. The cannulae (Clearpoint Neuro Smarflow Cannula) were primed with dosing solution containing 2 mM ProHance for infusion visualization and

marked at four depth locations. The cannulae were inserted to the proximal boundary of the target and advanced stepwise to optimize target coverage. Infusions commenced at 1 - 3 μL per minute. T1 scans were performed prior infusion and continuously during the infusions for distribution monitoring. The bilateral infusions were performed simultaneously. For all three animals, DICOM MR images were provided to Brainlab (Brainlab AG, Munich, Germany) for image post-processing and data analysis. For volumetric assessment a customized algorithm for auto-segmentation of the target structures and the infusate distribution by subtracting the baseline images from the post infusion images was applied. The infusate distribution volume overlapping the target structure was considered as coverage and is reported as a percentage of the target volume. **Results and Conclusion:** Six catheter placements were performed in three animals using the described procedure. Injection volumes of 85 - 125 μL per putamen, distributed over 4 injection sites, resulted in a coverage of 63 ± 3% of the putamen (maximum: 67%, minimum 58%). All catheters were placed on target. In conclusion, targeting the putamen for catheter placement by an occipital approach for simultaneous, bilateral CED infusions is feasible and effective in large animal species using the NBR Northern ARC Brain Infusion System. Analysis of infusate distribution through co-infused contrast agent showed high consistency in the level of target coverage.

1034 A High-Throughput AAV-Based Screening Platform for the Engineering of Cell-Type Specific Gene Regulatory Elements

Riccardo Privolizzi, Alba Guijarro Belmar, Panayiota Demosthenous, Hanna Luniak, Calvin C. Smith, Miranda A. Mathews, Raj S. Dattani, Robert M. Brownstone, Andrew J. Murray

Sania Therapeutics, London, United Kingdom

The fundamental cause of many neurological disorders can be ascribed to the abnormal electrical activity of specific neural circuits. Modifying the activity of neurons should therefore be a valuable avenue for the development of therapeutics to ultimately treat various nervous system conditions. However, for this to be a successful therapeutic approach, a high degree of specificity is required such that anomalous neuronal activity can be corrected in one circuit without altering the function of neighbouring cells and brain regions. To advance the treatment of neurological circuit disorders, Sania Therapeutics is leveraging a combination of intersectional technology platforms that allow for the targeted delivery of chemogenetic proteins through engineered adeno-associated virus (AAV) capsids and promoters. This approach will allow us to specifically modify neural circuit activity in disease states. Here we describe the development and validation of Gre-Scan, an AAV-based screening platform for the identification of cell type specific gene regulatory elements (GREs) such as promoters and enhancers. The use of cell type specific GREs is a promising way of targeting therapeutic genes to dysfunctional cell and tissue types. The ideal GRE for therapeutic purposes would drive high levels of gene expression in the targeted cell type, with minimal off target expression, whilst being compact enough to permit use within the limited packaging capacity of AAV vectors. Several fundamental challenges have so far precluded the identification and widespread use of cell type specific promoters, particularly in AAV-based genetic therapies. First, the relatively unmapped nature of gene regulatory elements within the genome has meant that identifying putative GREs has been challenging. Second, when potential GREs are identified there are few high throughput ways of measuring their activity in biological systems. Methylation-specific high throughput sequencing methods such as ATAC-Seq, combined with bioinformatics analysis, have vastly increased the number of putative GREs that could potentially drive cell type specific expression in AAV vectors. However, methods for the biological screening of these sequences have lagged behind and are generally restricted to laborious individual assessment, or tagging with genetic barcodes - the upper limit of which is generally in the 10s or 100s range per study. Here, we describe a biological screening platform that can be used for the high throughput screening of GRE activity across cell and tissue types. The screening process starts with the construction of large, diverse GRE libraries within AAV vectors. These libraries are built either through combinatorial expression of known transcription factor binding sites or putative GRE sequences identified by next generation sequencing. The Gre-Scan platform is then used to screen these libraries in parallel across multiple cell and tissue types. Sequences of interest identified by the platform can then be further validated on an individual basis. In a separate set of experiments we rationally designed a small library of GREs based on human motor neuron transcription factor binding sites and compared their activity in vitro individually and as part of the Gre-Scan platform. We have further validated this platform through the investigation of GREs that drive gene expression selectively in human motor neurons. We have built a human motor neuron specific GRE library and used the GRE-Scan platform to identify sequences that specifically drive gene expression in those neurons. This platform has led to the identification of the most promising candidates to take forward for in vivo testing for use in targeted therapeutics.

1036 EG-70, a Novel Non-Viral Gene Therapy Inducing Transgene Expression with Anti-Tumor Activity in the Peritoneal Cavity

Marie-Line Goulet, David Lazure, Kristine Sarah Louis, Sarah Stevenson, Sahar Amirkhani, Darius Bilimoria, Sébastien Sublemontier, Daniel Veilleux, Ximin Chen, Carlos A. Fleet, Anthony T. Cheung, James C. Sullivan

EnGene Inc., Montréal, QC, Canada

Background: enGene is developing a novel non-viral vector for gene therapy. The vector platform consists of a proprietary polymer, arginine-glucose derivatized-oligomeric chitosan (DDX), complexed with plasmid to form polydispersed nanoparticles with an average diameter of ~100nm. The core nanoparticle is further coated with an anionic methoxy-poly(ethylene glycol)-poly(L-glutamic acid) block copolymer. This delivery vehicle is stable in mucus and exhibits exceptional muco-penetration properties. EG-70 (detalimogene voraplasmid) is a nanoparticle formulation based on this DDX platform comprising a plasmid that expresses two non-coding RNA products that agonize the innate immune receptor retinoic acid-inducible gene I (RIG-I), as well as a single-chain recombinant human interleukin-12 (IL-12). This immunotherapy, with multiple mechanisms of action, has the potential to remodel the tumor microenvironment and bridge the innate and adaptive anti-tumor immune responses. In murine preclinical studies, EG-70 was found to be safe with minimal

and reversible local toxicity, to result in transfection of bladder urothelium, to produce the transgene products, and to drive a durable tumor-specific immune response in an orthotopic model of bladder cancer. EG-70 is being assessed in a Phase 1/2 clinical trial (LEGEND, NCT04752722) to evaluate its safety and efficacy in patients with Bacillus Calmette-Guerin (BCG)-unresponsive non-muscle invasive bladder cancer (NMIBC) and has shown promising preliminary outcomes in a first-in-human clinical study (NCT04752722). EG-70's formulation and anti-tumor mechanism are both broadly applicable for malignancies where there is unmet medical need. Patients afflicted with ovarian cancer are commonly diagnosed at an advanced stage and receive a poor prognosis. This study aims to evaluate the potential clinical benefit of EG-70 with intraperitoneal administration for ovarian cancer. **Results:** Intraperitoneal administration of a species-specific surrogate drug product (nanoparticles containing a plasmid DNA encoding for the mouse IL-12 homolog, along with the two RNA products) is well tolerated in mice. Local IL-12 protein expression, as assessed by MSD, is robust and reversible in the peritoneal lavage fluid. Dose-response studies were conducted to determine the optimal dose to drive high levels of expression, which is dependent on several factors including the volume of administration, the dose, and the concentration. Dose-dependent activation of downstream pharmacodynamic effects, such as IFNγ production, was observed. Administration of mEG-70 in a syngeneic murine model of ovarian cancer resulted in a significant reduction of tumor burden, compared to control animals. Further analyses are underway to characterize the remodeling of the tumor microenvironment following administration of EG-70. **Conclusion:** These results demonstrate that the novel DDX non-viral gene therapy platform can efficiently and safely deliver gene therapy to the peritoneal cavity for local anti-tumor transgene expression and drive a dose-dependent pharmacodynamic response. The level of transgene expression is biologically significant and supports the continued development of EG-70 for ovarian cancer or other malignancies within the peritoneal cavity.

1037 Development of Effective and Safe New Gene Therapy Drug (ARU-2801) for Hypophosphatasia

Tae Matsumoto[1], Noriko Miyake[2], Dongwei Zhao[3], Mohammad Shadid[4], Eric Gaukel[5], Sonoko Narisawa[6], Jose Luis Millan[6], Koichi Miyake[3]

[1]Department of Pediatrics, Nippon Medical School, Tokyo, Japan,[2]Department of Biochemistry and Molecular Biology, Nippon Medical School, Tokyo, Japan,[3]Department of Gene Therapy, Nippon Medical School, Tokyo, Japan,[4]Aruvant, New York, NY,[5]Roivant Sciences, Durham, NC,[6]Burnham Institute for Medical Research, La Jolla, CA

Hypophosphatasia (HPP) is an inherited bone disease caused by a deficiency of tissue-nonspecific alkaline phosphatase (TNAP). Enzyme replacement therapy requires subcutaneous injection 3-6 times a week for the rest of the patient's life. We evaluated the efficacy and safety of a gene therapy drug (TNAP-expressing type 8 adeno-associated virus vector; ARU-2801) to develop an alternative treatment. ARU-2801 [$1.0x10^{11}$, $3.0x10^{11}$, $1.0x10^{12}$ vector genomes(vg)/body] was injected intramuscularly once during the neonatal period (P1-3) to *Alpl* $^{-/-}$ mice, and survival, improvement of bone formation and plasma alkaline phosphatase (ALP) activity were investigated for 18 months. In Non-human primates (NHPs), ARU-2801 was injected once intramuscularly at 1.0 $x10^{13}$ vg/body and evaluated the safety for up to 84 days. All untreated *Alpl* $^{-/-}$ mice (n=4) died within 1 month. Over $3.0x10^{11}$ vg treated *Alpl* $^{-/-}$ mice (n=14) maintained high plasma ALP activity around 10,000 U/L and showed prolonged survival. *Alpl* $^{-/-}$ mice in the $1.0x10^{12}$ vg group (n=7) exhibited weight gain, and bone mineral density as well as wild-type mice. The treated *Alpl* $^{-/-}$ mice showed no abnormal blood chemistry tests, and no tumor formation or ectopic calcification. The treated NHPs also showed sustained plasma ALP activity with no toxicities. Thus, ARU-2801 was effective and safe in both *Alpl* $^{-/-}$ mice and NHPs. ARU-2801 could be a potentially life-prolonging and quality-of-life-improving agent for HPP patients that warrants further development as a novel treatment alternative to current enzyme replacement therapy.

1038 Positive Results from a First-in-Human Study Support Continued Development of PGNEDO51 for the Treatment of Duchenne Muscular Dystrophy (DMD)

Jane Larkindale[1], Michelle Mellion[2], Pallavi Lonkar[1], Jaya Goyal[1], Ashling Holland[3], Jeff Foy[2], Brijesh Garg[1], Shaoxia Yu[1], Jennifer Shoskes[2], Anthony Frank[2], Chris Abbott[2], Niels Svenstrup[2], Jennifer Cormier[2], Sarah Vacca[1], James McArthur[3]

[1]Clinical Science, PepGen, Tucson, AZ,[2]PepGen, Tucson, AZ,[3]PepGen, Cambridge, MA

Background: PepGen's Enhanced Delivery Oligonucleotide (EDO) cell-penetrating peptide technology is engineered to optimize tissue delivery and cellular uptake of therapeutic oligonucleotides. Delivery of oligonucleotides to affected tissues is a major challenge that limits their efficacy. PGN-EDO51 is being evaluated for the treatment of DMD amenable to exon 51 skipping. **Objectives:** To evaluate the safety, tolerability, pharmacokinetics (plasma and muscle), and pharmacodynamics (exon skipping) of single-ascending doses of PGN-EDO51 administered intravenously (IV) to healthy male volunteers (HV). **Methods:** Thirty-two adult HVs were randomized to receive a single dose of PGN-EDO51 (1, 5, 10, or 15 mg/kg; n=6 per cohort) or placebo (n=2 per cohort). Safety and tolerability were monitored over 28 days. Biceps needle biopsies were performed on Days 10 and 28 for measurement of tissue concentrations of PGN-EDO51 and exon skipping (pharmacodynamic biomarker to demonstrate target engagement). **Results:** All HVs completed the study. The majority of treatment-emergent adverse events were mild and resolved without intervention, including transient, reversible changes in kidney biomarkers (n=9) and hypomagnesemia (n=2) at the highest doses, with no significant clinical sequelae. At Days 10 and 28, respectively, there were dose-dependent and sustained concentrations of PGN-EDO51 measured in biceps biopsies: 9.7 nM and 3.8 nM (5 mg/kg); 19 nM and 11 nM (10 mg/kg); and 50 nM (both days at 15 mg/kg); and dose-dependent increases in mean exon skipping of 0.14% and 0.35% (5 mg/kg); 1.1% and 1.4% (10 mg/kg); and 1.4% and 2.0% (15 mg/kg). **Conclusions:** The Phase 1 study results demonstrate that PGN-EDO51 has a generally tolerable profile at clinically relevant doses. PGN-EDO51 exhibited high levels of muscle oligonucleotide delivery and

exon 51 skipping following a single dose. PGN-EDO51 concentrations and levels of exon skipped transcripts in muscle at Day 28 indicate the potential for accumulation of exon 51 skipped transcripts and dystrophin protein with repeat dosing in people with DMD amenable to exon 51 skipping. Based on these results, we plan to initiate a Phase 2, multiple-ascending dose study in people with DMD in the first half of 2023.

1039 Kinetics of Innate and Adaptive Immune Responses to Adeno-Associated Virus in a Preclinical Model

Alan D. Curtis[1], Rachel Hedinger[1], Lorne Celentano[1], Charles Krause[1], Layth Awartani[1], Dylan Southers[1], Christine Daniels[1], Sherif Gabriel[1], Audry Fernandez[1], Shari Gordon[1], R. Jude Samulski[1,2]

[1]Asklepios BioPharmaceutical, Inc., Durham, NC,[2]University of North Carolina at Chapel Hill, Chapel Hill, NC

Adeno-associated virus (AAV) vectors are leading candidates for gene therapy product delivery. However, immune responses to AAV or transgene products represent major hurdles to widespread clinical use. AAV induces long-lived T and B cell responses that have the potential to eliminate transgene expressing cells and prevent re-dosing. Thus, characterizing the anti-vector innate activation, adaptive responses and their influence on transgene longevity is of great interest. AAVrh32.33 is a highly immunogenic capsid that induces robust T and B cell responses in mice making it a useful preclinical model. Innate immune activation triggered by the vector facilitates antigen presentation and priming of B and T cell responses (Mays et al. 2009, Faust et al., 2013, Mays et al., 2014). In this study, we investigated the kinetics of innate and AAV-adaptive responses and long-term transgene expression following intramuscular (IM) delivery of AAVrh32.33. We assigned groups (n=4) of adult female B6(Cg)-Tyrc-2J/J albino mice to receive AAVrh32.33 carrying a luciferase reporter (AAVrh32.33-CBA-Luc) or mock vehicle by IM injection into the right tibialis anterior. IVIS imaging monitored luciferase transgene expression in life and at sacrifice. Mice were sequentially sacrificed at 2, 5, 8, 14, 24, 72 hours or on days 7, 30 or 98 post-dose. Resiquimod (R848), a TLR7/8 agonist, was used as a positive control for innate stimulation and given to mice at 100 μg dose by IV/IM injection. Immune gene expression in the muscle was assessed by quantitative PCR of mRNA extracts and reported as relative fold change over mock-treated animals. An upregulation of select innate genes including interferon gamma induced protein 10 (IP-10) was observed beginning at 24 hours post dosing (~4 fold). In contrast, R848 induced robust expression of IP-10 2-5hr post dose (100-350-fold). AAV specific antibodies were measured by ELISA and T cell responses were assessed by IFN-γ ELISPOT and multi-parameter flow cytometry staining. By day 30, AAVrh32.33 induced high titer antibodies and robust T cell responses measured in the spleen (ELISPOT ≥1500 spot forming units per million). Additionally, antigen experienced AAVrh32.33pMHCI dextramer positive cells were present in spleen, liver, and bone-marrow (1-5% AAV dextramer$^+$ CD8 T cells). Gene expression analysis in the muscle indicated T cell infiltration as CD4 (51-fold), CD8 (174-fold), IFN-γ (79-fold) and IL-12 (433-fold) all increased in AAV treated animals relative to mock controls. Antibody and T cell responses contracted over the following 2 months but were still detectable at day 98. Luciferase transgene expression was detected in the muscle of AAV transduced mice by 8h and draining (popliteal and inguinal) lymph nodes by 24h. Transgene expression increased in magnitude during the first 14 days post AAV dosing, plateaued, and persisted at high levels for the duration of the study. Overall, the development of functional AAVrh32.33-specific T cell responses and T cell infiltration within the muscle did not ablate transgene expression. Thus, the persistence or loss of transgene is not solely dependent on the immunogenicity of the capsid used.

1040 5′ UTR Design for High Protein Expression Efficiency of mRNA Therapeutics/ Vaccines

Minsa Park[1], Jin-Wu Nam[2], Seokju Park[2], Kyuri Lee[1]

[1]Gyeongsang National University, Jinju-si, Gyeongsangnam-do, Korea, Republic of,[2]Hanyang University, Seongdong-gu, Seoul, Korea, Republic of

The 5′ untranslated region (5′ UTR) of mRNA is a crucial element in determining the translation efficiency of mRNA therapeutics/ vaccines. Therefore, understanding the 5′ UTR sequences that induce high ribosome loading efficiency is important for designing mRNA therapeutics/vaccines exhibiting high protein expression efficacy. In this regard, there have been various attempts to develop algorithms to predict the ribosome loading efficiency of 5′ UTR sequences and generate artificial 5′ UTR sequences expected to show high translation efficiency. The algorithms have been developed primarily based on the massively parallel reporter assays (MPRAs) of the 5′ UTR random library. However, the dataset of the current approaches inevitably contains a non-randomized additional sequence for primer binding at the 5′ ends of the 5′ UTR, which limits the exploration of the effect of the 5′ ends of the 5′ UTR library. To overcome this, we prepared a fully randomized 5′ UTR library without introducing additional sequences. Using this, we sought to dissect the role of 5′ ends of the 5′ UTR in determining ribosome loading and translation efficiency of mRNAs. Also, we tried to develop a 5′ UTR design algorithm to achieve high protein expression efficiency of mRNA therapeutics/vaccines.

1041 Amino Acid Analysis Indicates Metabolic Differences in Multi-Cytokine Backpack -Manufactured CAR T-Cells

Biaggio Uricoli[1], Heather Lin[2], A K M Nawshad Hossian[3], Ji Young Anderson[4], Kerin Gregory[5], Milla Neffing[6], Graziella Piras[5], Sarwish Rafiq[3], Erik Dreaden[1]

[1]Wallace H. Coulter Department of Biomedical Engineering, Emory University, Atlanta, GA,[2]Emory University, Decatur, GA,[3]Emory University, Atlanta, GA,[4]Research and Development, 908 Devices Inc, Boston, MA,[5]908 Devices Inc, Boston, MA,[6]Bioprocessing, 908 Devices Inc, Boston, MA

Novel reagents that aid in the consistent manufacturing of CAR T-cells with well-defined phenotypes are needed to improve treatment outcomes in patients. Traditional *ex vivo* expansion reagents provide only TCR activation and co-stimulation. Recently developed multi-cytokine backpacks (MCBs, Ref 1) have been shown to provide CAR T-cell manufacturing with additional cytokine support, critical for cell expansion, differentiation, and the selection of potent, long-lived phenotypes. A commonly used method for *ex vivo* activation is using the cytokine IL-2 with Dynabeads™. In this project (Ref 1) different

combinations of immunomodulating proteins were used to create an MCB library. The activated cells were tested for viability, CAR expression, phenotype and *in vivo* activity (Ref 1). Here we describe the amino acid (AA) analysis done with the REBEL device (908 Devices) to assess differences in the metabolic activity in these activated cells. The differences in metabolism were measured for all groups with Dynabead + exogenous IL-2 as the control and a reference point. **Methods** The T-cells were isolated and transduced as described in Ref 1. after activation, the cells were expanded in RPMI-1640 + 10 % FBS in a total volume of 200µL. AA concentrations were measured from the fresh and spent (end-point) media using the REBEL (908 Devices Inc.), a capillary-electrophoresis (CE) - mass spectrometry (MS) -based device for AA analysis. CAR T-cell products were isolated via centrifugation / 400xg for 5 minutes, and the cell-free supernatant was diluted 1:10 with manufacturer-provided diluent. Automated quantitation of AAs for each sample was achieved using embedded calibrations. Two biological replicates of each sample were analyzed in triplicate using the REBEL. The nutrient compositions of the final CAR T-cell product spent media were analyzed to identify differences in their cellular metabolism. The ratio of the mean AA concentrations from the microparticle backpack library samples to the mean concentrations from the control samples (Dynabead + IL-2) were plotted using 908 Devices add-in for JMP software. **Results** Based on several biological assays, the MCB library particles [UB3] were categorized as "high", "intermediate", and "low" activity with respect to CD8+ and CD4+ less-differentiated CAR T-cell phenotypes (T_{CM} and T_{SCM}). A focus on the top candidates (#09, #16, #27, and #43) spent media samples interestingly showed differences as compared to control in concentration for the AAs Ala, Gln, Gly, Pro, Ser, Thr. It was observed that some AAs (ie. Ala, Gly, Ser) were accumulating in the media during culture in all samples, whereas some (Arg, Ser) were consumed. **Conclusions** AA analysis is not regularly performed as part of CAR T-cell experiments due to the complexity of many traditional analysis methods and sample volume limitations. With automated quantitation and low sample volume requirements, the REBEL device enables rapid analysis at the bench side with no requirement for prior MS expertise. Studies to define relationships between AA dynamics, T-cell metabolism, and CAR T-cell biology are currently in progress; however previous findings by Ref 2 indicate that AAs are critical for efficient T-cell activation and proliferative responses. With this work we demonstrate a correlation between CAR T-cell activation, nutrient metabolism, and subsequent therapeutic efficacy. Ref 1 - Lin and Uricoli et al. 2023 Nature Biomedical Engineering; Submitted Ref 2 - Cobbold SP, *et al*. Proc Natl Acad Sci U S A (2009) 106:12055-60

1042 Development of an AAV-Based microRNA Gene Therapy for Myotonic Dystrophy Type 1

Giulio Srubek Tomassy[1], Wei Fan[1], Alessandro Magli[1], Tracy Zhang[1], Kristen Boyle[1], James Cao[2], Robert Jackson[1], Jennifer Sullivan[1], Amy M. Frederick[1], Catherine O'Riordan[1], Martin Goulet[1], Christian Mueller[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]Global Bioimaging, TIM, Sanofi, Cambridge, MA

Myotonic Dystrophy Type 1 (DM1) is the most common form of adult muscular dystrophy (~1:8000) characterized by life-threatening muscle weakness, compromised respiration and often cardiac conduction abnormalities with high unmet medical need. DM1 is caused by a CTG repeat expansion in the 3' untranslated region (UTR) of the dystrophia myotonica protein kinase (DMPK) gene, resulting in DMPK mRNA hairpin structures that aggregate as insoluble ribonuclear foci and sequester several RNA-binding proteins. The resulting redistribution of essential splicing factors, such as muscleblind-like 1 (MBNL1), causes mis-splicing of downstream effectors responsible for the differentiation of muscle tissue. Targeting DMPK RNA appears to hold some of the greatest prospects for therapeutic intervention in DM1. Gene therapies with siRNA or ASOs against DMPK mRNA have shown promise in animal models and in clinical trials, but require repeated administrations. To overcome this limitation, we developed an artificial miRNA to target human DMPK mRNA for constitutive expression following systemic delivery of a recombinant adeno-associated vector (rAAV). To determine the potential of amiRDMPK to correct the DM1 phenotype, we first tested their ability to silence the human DMPK transcript and correct splicing defects in DM1 patient cells. The treatment of those cells with amiRDMPK caused over 50% DMPK mRNA silencing and splicing defect correction measured by MBNL1 exon 7 inclusion. Next, we evaluated the same approach in the DMSXL mice, a DM1 mouse model carrying a human *DMPK* gene with toxic CTG repeats. Our results show that a single intravenous injection of the AAV vector expressing the amiRDMPK, resulted in significant reduction of the toxic human nuclear DMPK mRNA in muscle, including the heart. Consequently, a reduction in the number of nuclear foci and reversion of splicing abnormalities were observed. Furthermore, treatment with amiRDMPK improved body weight, survival rate, cardiac and skeletal muscle function. Lastly, we tested our approach in non-human primates (NHP), testing three different doses. In this study, we found a significant, dose-dependent accumulation of AAV genomes in all the relevant tissue (namely skeletal and cardiac muscle). This resulted in dose-dependent reduction of DMPK expression, up to 90%, as compared to a control group. Importantly, all doses tested in NHPs resulted to be safe and well-tolerated. Overall, our data provide evidence on the efficacy of artificial miRNAs against *DMPK* as a promising AAV-based gene therapy for DM1.

1043 RNA Reprogramming Therapeutics Based on Tetrahymena Group I Intron for Hepatocellular Carcinoma

Seungryul Han[1], Jihyun Kim[1], Hye Rim Park[1], Sungwoo Hong[1], Bomi Kim[1], Seong-Wook Lee[1,2]

[1]Rznomics Inc., Seongnam-si, Korea, Republic of,[2]Dankook University, Yongin, Korea, Republic of

Group I intron-based trans-splicing ribozyme enables to sense and reprogram target RNA into gene of interest through RNA replacement. Previously, we proposed hTERT-targeting trans-splicing ribozyme harboring therapeutic suicide gene for cancer therapy. Hepatocellular carcinoma (HCC) is major type of primary liver cancer, and its incidence and mortality rates are steadily increasing. However, HCC has high fatality rate and limited therapeutic options. Recently, Immune checkpoint inhibitor for activating the function of T cells is the fastest growing therapeutic option in the cancer therapy, but immunotherapy has low response rate and limitation to applying it to all cancer patients. Here, we optimized the specific ribozyme for highly efficient

anticancer activity with less off-target effect for anti-HCC approach. To confer potent anti-HCC effects and minimize hepatotoxicity, we constructed post-transcriptionally enhanced ribozyme expression cassettes harnessed with splicing donor, acceptor site, and woodchuck hepatitis virus post-transcriptional regulatory element under the control of microRNA-122a, the expression of which is down-regulated in most HCC. Then, systemic or local administration of adenovirus encoding our refined ribozyme, termed RZ-001, achieved great anti-cancer efficacy and improved ability to specifically target cancer without hepatotoxicity in both nude and humanized xenograft mice model. Of note, the immune cells were found to be effectively infiltrated into cancer tissue after RZ-001 administration in the humanized xenograft mice model. Through GLP toxicity and biodistribution study, minimal liver toxicity and tissue distribution and clearance pattern of the recombinant adenovirus were observed in normal animals administered systemically. Based on these results, RZ-001 recently received IND approval for first-in-human clinical 1/2a trials of group I intron based trans-splicing ribozyme from the Korean Ministry of Food and Drug Safety and the United States FDA, and was administered to the first HCC patient. Reprogramming of hTERT mRNA by post-transcriptionally regulated RNA replacement strategy mediated by a cancer-specific ribozyme would provide a clinically relevant, safe, and efficient strategy for HCC treatment.

1044 Biodistribution Assessment in Non-Human Primates of JAG201, a *SHANK3* AAV9 Vector Delivered via ICV Injection for ASD, Phelan-McDermid Syndrome, and Other SHANK3 Mutation or Deletion Related Conditions

Michael Hughes, Janet Do, Joel Cooper, Daniel McCoy
Jaguar Gene Therapy, Lake Forest, IL

Background: The SH3- and ankyrin repeat (SHANK) protein family are major scaffolds of the post-synaptic density of excitatory synapses, where loss of *SHANK3* function provokes synaptic dysfunction in the brain. Affected patients present with a debilitating neurodevelopmental disorder characterized by severe intellectual disabilities, impaired or absent speech and language, deficits in motor skills, behavioral challenges, and autism and/or autistic features. JAG201 is as an investigational AAV9-based gene therapy in preclinical development intended to deliver a functional version of *SHANK3* to treat autism spectrum disorder (ASD), Phelan-McDermid syndrome (PMS), and other neurodevelopmental disorders that result from a mutation or deletion within the gene or from chromosomal rearrangements at 22q13.3 spanning *SHANK3*. Genetic sequencing studies indicate that *SHANK3* mutations or deletions may be present in ~1% of patients with ASD, equating to about 30,000 patients in the U.S. Here, we present data from a non-GLP study in NHPs evaluating the biodistribution of vector genome DNA and RNA transgene expression of JAG201 in the CNS and peripheral organs following unilateral and bilateral intracerebroventricular (ICV) administration. ***Methods:*** 24 NHPs (12 males and 12 females) aged approximately 2-3 years received either a single ICV administration of vehicle or JAG201 via unilateral or bilateral injection at a dose of 1.0E13 or 1.0E14 vg/animal in a total volume of 2.0 mL given via bolus injection. Injection coordinates were determined via MRI followed by stereotaxic administration targeting the lateral ventricles. Animals were followed for a 90-day in-life period, and biodistribution of JAG201 vector DNA and RNA in CNS and peripheral tissues were analyzed via droplet digital PCR (ddPCR) and supported via RNA fluorescence *in situ* hybridization (FISH). ***Results:*** The unilateral and bilateral ICV administration procedures and single doses of JAG201 were well tolerated. At 90 days, animals that received JAG201 showed widespread rostrocaudal transduction throughout the CNS in a dose-dependent manner compared to vehicle controls. Analysis of JAG201 vector genome DNA copies in five key brain regions showed the highest levels of transduction in the frontal cortex and hippocampus, followed by the cerebellum and spinal cord, at both dose levels. Widespread transduction of the striatum and thalamus was observed at the higher JAG201 dose level. These findings were supported and mirrored by JAG201 RNA quantification and RNA FISH analysis, with dose-dependent expression observed in all evaluated brain and spinal cord regions. Additionally, unilateral and bilateral JAG201 administration resulted in comparable overall levels of vector DNA and RNA copies throughout the brain, including comparable levels in both the contralateral and ipsilateral sides of the brain. Analysis of vector DNA copies in peripheral tissues confirmed leakage of vector from the CNS, however in contrast to the CNS, significantly lower relative levels of RNA expression were observed as a result of the highly neuron-specific activity of the human synapsin promoter limiting off-target transgene expression. ***Conclusion:*** These data provide evidence that both unilateral and bilateral ICV administration of JAG201 result in comparable widespread biodistribution throughout the CNS. Further, JAG201 RNA expression analysis confirms widespread expression throughout the brain and spinal cord while limiting off-target expression in peripheral tissues. In summary, these findings confirm the selection of unilateral ICV administration for further evaluation of JAG201, a *SHANK3* AAV9-based gene therapy targeting *SHANK3* mutation or deletion related disorders.

1045 Senescent Cells Accumulation During Human Muscle-Derived Stem Cells Expansion Negatively Affects BMP2-Mediated Bone Regeneration

Xueqin Gao[1], Mingtai Hwang[2], Aiping Lu[1], Matthieu Huard[1], Joseph J. Ruzbarsky[3], Yadong Wang[2], Johnny Huard[1]
[1]Linda and Mitch Hart Center for Regenerative and Personalized Medicine, Steadman Philippon Research Institute, Vail, CO,[2]Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY,[3]Shoulder, Knee, Elbow & Hip Preservation Surgery, The Steadman Clinic, Basalt, CO

Introduction. It has been shown that human muscle-derived stem cells (hMDSCs) can promote bone regeneration in a critical sized calvarial bone defect when transduced with lenti-viral BMP2. Coacervate is a polymer that can sustained-release growth factors for tissue engineering applications. The aim of this study is to use the coacervate sustained release platform to investigate whether coacervate delivered BMP2 can promote bone formation and if adding human muscle-derived stem cells is beneficial for bone regeneration mediated by BMP2-coacervate.

Methods. **1.** Synthesis of poly (ethylene argininylaspartate diglyceride) (PEAD) and heparin coacervate was performed as previously reported. **2. hMDSCs** were isolated with a modified pre-plate technique and transduced with lenti-GFP. **3. *In vivo* bone regeneration using critical sized calvarial bone defect model**: male ISCRSCID mice were divided into 2 groups (n=6): group 1: 2 μg BMP2+coacervate+1.5×10^6 hMDSCs/LGFP; group2: 2 μg BMP2+coacervate. Fibrin sealant was used as a scaffold. Critical sized 5mm calvarial bone defects were created on the right parietal bone of mice. For the BMP2+coacervate+hMDSCs group, the BMP2 coacervate was first mixed with hMDSCs (20ul in PBS) and then added 20ul thrombin, mixed, added to the defect, then 20ul fibrinogen was added to the defect, and allowed to form a fibrin gel. For the BMP2+ coacervate group, BMP2 coacervate was mixed with 20ul thrombin, added to the defect, and then 20ul fibrinogen was added. **4. MicroCT and histology**. Bone regeneration was quantified using the Viva-CT 80 at days 1, 14, 28 and 42 lively. Mice were sacrificed at 6 weeks after surgery and skulls were harvested and fixed in formalin for histology. H&E, Herovici's staining was performed to reveal general morphology and bone matrix collagen 1 (Col1). **5. Cellular senescent detection**. hMDSCs/LGFP at passage 6 and 10 after lenti-GFP transduction were seeded in 24 well plate and cultured for 48hrs. 3 wells of each passage were used for senescent associated-β-gal staining, while 3 wells from each passage were used for total RNA extraction, Q-PCR for P16INK4a and interleukin 1β. **Results.** MicroCT results showed limited new bone formation in the BMP2+coacervate+hMDSCs group while the BMP2 coacervate group (without cells) showed robust new bone formation. BMP2+coacervate group regenerated significantly more new bone than the BMP2+ coacervate+hMDSCs/LGFP group at all time points. H&E staining showed small island-like areas of bone in the defect area in the BMP2+coacervate+hMDSCs group. In contrast, functional new bone with bone matrix and bone marrow was formed in the BMP2 coacervate group**.** Herovici's staining showed nearly no new bone was formed in the middle of the defect of the BMP2+coacervate+hMDSCs/LGFP group. However, half of the defects were filled Col1 positive new bone in the BMP2+coacervate group. These unexpected results further prompted us to investigate why adding hMDSCs decreased new bone formation mediated by BMP2 coacervate. We found that more SA-β Gal positive cells are present at passage 10 (the cell passage we used in vivo for this study) when compared to passage 6. The P16 and IL1β also increased in passage 10 compared to passage 6. **Conclusion.** Our study revealed that the use of coacervate to deliver BMP2 regenerated new bone that are comparable to Lenti-BMP2 transduced hMDSCs as reported previously. However, to our surprise, adding later passage of hMDSCs to BMP2 coacervate significantly decreased new bone formation despite using same dose of BMP2. This adverse effect was likely due to accumulation of senescent cells at advanced passage.

1046 Separation of Empty, Partial, and Full Capsids Using Multicolumn Chromatography

Vijesh Kumar, Ohnmar Khanal, Mi Jin

Technical Development, Downstream, and Drug Product Development, Spark Therapeutics, Philadelphia, PA

AAV capsids that carry and deliver the desired transgene to the target cells are one of the most popular viral gene transfer vectors. In addition to capsids carrying the desired transgene, AAV production often results in many capsids devoid of the transgene (empty capsids) or containing a truncated transgene (partial). Before downstream purification, these capsid variants are often present in a larger percentage than the full capsids and can potentially reduce the vector's effective dosage. Product consistency also necessitates proper control of the product profile in the final drug substance, calling for a scalable purification method that can separate these product variants. Furthermore, the enrichment and separation of these variants can enable the proper characterization of each variant and the investigation of its biological impact. Anion exchange chromatography (AEX) is widely used to separate empty and full capsids. However, the enrichment and separation of partial capsids with anion exchange chromatography have not been demonstrated in the industry. Partial AAV capsids are heterogeneous and have features that overlap with full capsids, making it difficult to separate them from full AAV capsids. Typically, a shallow salt gradient elution separates empty and full capsids. Often, sufficient resolution between empty and full capsids cannot be obtained, and the reliance on salt gradient elution often leads to lower product yield. In this work, empty, partial, and full capsids are enriched and separated by self-displacement chromatography, wherein variants with a stronger affinity to the AEX resin displace the variants with a weaker affinity to the resin. We demonstrate unparalleled separation of empty, partial, and full capsids with single- and multicolumn anion exchange displacement chromatography. The approach employed here will help to control product variants and, in general, aid in their isolation to enable further characterization.

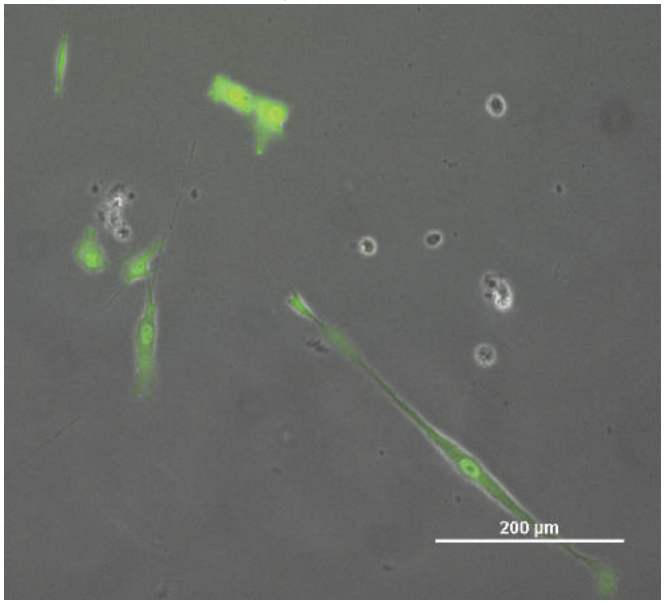
1047 MyoSite Human Skeletal Muscle-Derived Cells (skMDC) as a Tool for Studying Neuromuscular Disorders

Kyle E. Harvey[1], Steven J. Charlebois[1], James Cummins[2]

[1]MED Institute, West Lafayette, IN,[2]Cook MyoSite, Pittsburgh, PA

Cultured myoblasts are a valuable tool in cell biology for studying underlying mechanisms of neuromuscular and metabolic disorders, including muscular dystrophies and Type II diabetes. Immortalized cell lines, such as C2C12 myoblasts have played a pivotal role in the research of in vitro research in neuromuscular diseases. However, these cells are mouse derived and may not accurately model neuromuscular processes in humans. Primary human skeletal muscle derived cells (skMDCs) are proliferative myoblasts that are capable of differentiation into multi-nucleated myotubes. skMDCs can be isolated from both healthy donors, as well as donors with inherited mutations such as those implicated in muscular dystrophies. Gene editing in both C2C12 cells and primary myoblasts has shown to be challenging due to difficulties in transfection. Lipid-mediated transfection by commercially available reagents while highly efficient in various immortalized cell lines, can be more challenging in primary cells. Electroporation is an alternative method to introduce plasmids and ribonucleoprotein into cells through transiently increasing the permeability of the cell membrane by application of a short electric pulse. One major drawback to electroporation-mediated transfection is cell death during the pulse, thus requiring optimization. In the present study, we evaluated the transfection efficiency of an enhanced green fluorescent protein (eGFP) containing plasmid using the Bio-Rad GenePulser XCell™ system in MyoSite skMDCs. skMDCs were cultured in MyoTonic™ Basal Media supplemented

with MyoTonic™ Growth supplement, 100 U/mL penicillin, and 100 µg/mL streptomycin, and cultures were maintained at 37 °C with 5% CO2. Prior to electroporation, cells were trypsinized and resuspended in complete MyoTonic™ Media without antibiotics to a concentration of 100k cells/100 µL. GFP containing plasmid was added to the cell suspension at 10 µg/mL and the cell were pulsed at 170V, 975 µF in 2 mm cuvettes using an exponential decay protocol. Cells were then diluted in complete media and plated in 6-well plates. eGFP expression was assessed 48 hours after electroporation by fluorescence microscopy. Analysis was performed using NIS-Elements BR (Nikon).



Transfection of eGFP by this approach with electroporation resulted in a transfection efficiency greater than 50% as determined by the number of GFP positive cells. Our results using eGFP as a reporter for transfection efficiency suggest that MyoSite skMDCs may serve as a cellular model requiring plasmid transfection or introduction of gene-editing materials in studies exploring molecular mechanisms of muscle cell development and neuromuscular disease.

1048 Multi-Gene Co-Transfection is Dependent on Transfection Method

Uday Baliga[1], Anthony Gurunian[2], David A. Dean[2]

[1]Pathology and Laboratory Medicine, University of Rochester, Rochester, NY,[2]University of Rochester, Rochester, NY

Delivery of multiple genes to a single cell is necessary for many research and therapeutic purposes, including generation of iPSCs, viral reverse genetics, and molecular pathway analyses. However, as increasing numbers of distinct genes are delivered, the efficiency of every distinct gene being delivered to a given cell is reduced. This creates an expensive and frustrating bottleneck in multigene studies and may complicate analysis when some cells only receive part of the total desired genetic cargo. Various non-viral transfection methods have been used to co-deliver multiple genetic cargoes, most commonly lipofection and electroporation. We analyzed co-transfection of both methods through their ability to deliver plasmids expressing different fluorescent proteins. We further evaluated how increasing the amount of plasmid used in the transfection affected co-transfection and cytotoxicity. Co-transfection was analyzed using spectral flow cytometry and fluorescence microscopy, and cytotoxicity was analyzed using an LDH assay. By transfecting A549 cells we found that increasing the number of distinct plasmids being delivered resulted in fewer co-transfected cells, regardless of method. Lipofection resulted in greater co-transfection of A549 cells relative to electroporation. However, when using lipofection, increasing the number of distinct plasmids or increasing the quantity of plasmids delivered resulted in an increased cytotoxicity. Electroporation did not show this increased cytotoxicity with increased number of plasmids or quantity of plasmids, despite a higher baseline cytotoxicity. Increasing the amount of plasmid being delivered by electroporation also improved co-transfection. These data indicate that (1) the choice of transfection agent affects co-transfection and (2) increasing plasmid quantity in electroporation improves co-transfection.

1049 New 4th Generation Lentiviral Vectors with Simplified Vector Genome RNA Biosynthesis: How to Inactivate the Major Splice Donor Site and Retain High Titre

Jordan Wright, Ben M. Alberts, Cristina Nogueira, Thomas Evans, Sara Ferluga, Daniel D. Chipchase, Kyriacos A. Mitrophanous, Nicholas G. Clarkson, Dan C. Farley

Oxford Biomedica, Oxford, United Kingdom

To advance the utility of Lentiviral vectors (LVVs) it will be necessary to further improve the quantity and quality of vectors produced. The HIV-1 genome is structurally complex, with *cis*-acting elements including the major splice donor (MSD), multiple splice acceptor (SA) sites, packaging signal (Psi), and Rev-response element (RRE) governing production of unspliced and spliced RNA. Standard 3rd generation LVVs retain minimal HIV-1 sequences in their vector genomic RNA (vRNA) including Psi and RRE, in such a configuration that theoretically splicing activity is suppressed by Rev, leading to production of unspliced cytoplasmic vRNA for packaging. However, in reality up to 95% of vRNA transcripts may be spliced from the MSD to strong or cryptic SAs located within the transgene expression cassette, even when Rev is supplied during LVV production. Whilst only the unspliced vRNA contains a full Psi sequence, these aberrantly spliced mRNAs can lead to transgene protein production during manufacture, which is undesirable in the final vector product, even when tissue-specific promoters or other methods such as the TRiP System™ are employed to suppress expression (doi: 10.1038/ncomms14834). Addressing this issue through mutating the MSD is challenging due to its location within Psi. An intact MSD has also been shown to suppress the HIV-1 5' R polyadenylation site through recruitment of U1 snRNA - a redundant function shared with the auxiliary protein Tat. Accordingly, mutation of the MSD leads to a substantial decrease in LVV titres, and renders them Tat-dependent, which is clinically undesirable. We report on a new class of MSD-inactivated LVV genomes that do not aberrantly splice, leading to simplified production of a greater proportion of full length, packageable vRNA. These genomes are therefore also preferential when used in conjunction with the TRiP System™. An optimal MSD mutant was identified that minimises the attenuating effect on titres, and avoids activation of local cryptic

splice donor sites. Critically, Tat-independent production of these MSD-inactivated LVVs can be realised by two approaches. In the first approach, used for LVVs retaining the RRE so that transgene cassette introns are retained, a modified U1 snRNA molecule targeted to the Psi RNA region is co-expressed during production. In contrast to reported U1 snRNA functions, modified U1 snRNA was found to rescue titres independently of 5' polyA suppression. Through optimisation U1 snRNA binding length and target, MSD-inactivated LVV titres could be fully rescued to those of MSD-intact LVVs. Surprisingly, we also observed that modified U1 snRNAs were often found to improve the titres of 3rd generation (MSD-intact), clinical LVVs by 2-to-7 fold. The second approach is to use an MSD-inactivated LVV genome with a synthetic intron ('Vector-Intron' [VI]) in place of the RRE, thus making such LVV genomes Rev-independent. Splicing-out of the VI stabilises the vRNA, and therefore use of the modified U1 is not required. Together with additional deletions within the Psi-gag region, this liberates ~1kb of additional space. These 'MaxPax' LVVs cannot retain transgene cassette introns, and are therefore being evaluated for very large inserts where transgene space is limited, and introns are not desirable. Finally, these novel genomes, in combination with the TRiP System™, are being evaluated for use in generating stable producer cell lines for CAR-LVVs, where efficient suppression of the CAR protein appears to be correlative with success. The MSD-inactivated feature forms a core aspect of our 4th generation LVVs, and will be an attractive platform for future LVV product development in general.

1050 Superior Cytotoxic Signatures of Cord Blood Stem Cell-Derived Natural Killer Cell Therapeutics Identified with Bulk and Single-Cell Transcriptomics Analysis

Monica Raimo[1], Amanda van Vliet[1], Mirjam van den Hout[2], Daniëlle Steenmans[1], Adil D. Duru[1], Anna-Maria Georgoudaki[1], Wilfred van Ijcken[2], Jan Spanholtz[1]

[1]Research, Glycostem Therapeutics, Oss, Netherlands,[2]Erasmus Center for Biomics, Rotterdam, Netherlands

Glycostem Therapeutics has developed a closed, automated, and feeder-free system (uniK™) for *ex vivo* expansion and differentiation of umbilical cord blood-derived $CD34^+$ stem cells into highly functional, cryopreserved, truly off-the-shelf GTA002 NK cells, currently evaluated in a Phase I/II clinical study in AML, WiNK (NCT04632316). GTA002 batches are each generated from a different stem cells donor, however show similar patterns of expression of cell surface receptors and potent *in vitro* cytotoxicity against a variety of tumor cell lines. Nevertheless, the interindividual variability between donors may result in heterogeneity of functionality, which could not be predicted beforehand. Therefore, we investigated the transcriptome profile of multiple GTA002 batches, comparing the bulk (population level) and single cell (sub-population level) RNA-sequencing profiles. We actively selected batches with biological heterogeneity by comparing their *in vitro* cytotoxic potential against various cancer cell lines, evaluated under challenging low E:T ratio conditions. First, we selected 10 GTA002 pre-clinical batches, for which we monitored relevant biological parameters as surface receptor profile and potency, to distinguish a group of superior killers (4/10), compared to the rest (6/10). Next, we used bulk RNA-seq to investigate gene expression differences between the two groups. Interestingly, we found distinct, similar, transcriptional patterns for superior killers, and determined gene expression signatures via gene set enrichment and pathway analysis. In parallel, we pursued in-depth investigation of batch sub-populations by performing topological and clustering analysis via scRNA-Seq, also including multiple batches produced under good manufacturing practice (GMP) conditions. In depth-transcriptomics analysis of GMP batches is pivotal to advance our product understanding towards standardized off-the-shelf, allogeneic, NK cell therapies. Identification of biomarkers of excellent batches can then be linked to therapeutic efficacy, to provide the most appropriate product to a given patient. This research contributes to the development of universal cell therapies by generating a deep understanding of underlying donor- or process-induced variability, which is highly relevant and applicable to products originating from different sources, like induced pluripotent stem cells-derived NK cells (iPSC-NK).

1051 Establishing Product Quality Standards Early Streamlines Regulatory Filing for AAV Gene Therapy Vectors

Catalina Troche, Melissa Breedlove, Susan D'Costa

Alcyone Therapeutics, Lowell, MA

Implementing Quality by Design (QbD) principles early during product development is critical to ensure commercial success for therapeutics. QbD requires understanding the quality target product profile (QTPP) ahead of product development to determine the quality attributes of the final product. Critical quality attributes (CQAs) of potency, purity, identity, and safety are then determined through a risk assessment of these attributes. Beyond risk management, robust analytical methods are necessary to measure these attributes and present a clear control strategy to regulatory agencies. The ACTX-101 process was developed as a scalable suspension system with agnostic downstream operations platformed for AAV9 serotype vectors. Utilizing the principles of QbD, product-specific impurities were identified as key critical quality attributes. These product-specific impurities include: encapsidated plasmid and host cell DNA, empty and partially filled capsids, aggregated/deamidaded/glyclosylated forms, and replication-competent AAV. We will present a case study specific to these CQAs and their impact on potency and safety.

1052 DRIMER: Optimized Programmable RNA Scaffolds for Multivariate Multiple and Different Effector Recruitment Using CRISPR/dCas9

Alan Cabrera, Barun Mahata, Yannie Guo, Daniel Reed, Hailey Szadowski, Suchir Misra, Jing Li, Isaac Hilton

Bioengineering, Rice University, Houston, TX

Rational engineering of RNA has enabled diverse applications ranging from COVID vaccines to improved guide RNA (gRNAs) for CRISPR/Cas systems *in vivo* and *in vitro*. For instance, nearly all CRISPR/Cas9-based genome editing applications rely upon gRNAs that are synthetic fusions between the CRISPR and trans-activating CRISPR RNAs (crRNAs and tracrRNAs, respectively). Further, chemical modifications to gRNAs are often required for genome editing in cell and gene therapy contexts as well as CRISPR activation (CRISPRa) strategies. gRNAs are

frequently modified to incorporate stem-loops that can recruit RNA binding proteins fused to different transcriptional effectors. However, these stem-loop platforms currently offer limited spatiotemporal control and can sometimes even interfere with gRNA efficacy. Here we developed and optimized a designer RNA intermediated effector recruitment platform, called DRIMER that permits robust stochiometric and spatiotemporal control over effector recruitment in CRISPR/Cas systems. DRIMER can recruit up to four different effector domains to human loci. Importantly, these effectors can be functionally distinct and recruited in user-defined combinations. For instance, using the DRIMER system, we demonstrated powerful synergistic effects following the recruitment of multiple synthetic transcription factors and epigenetic editors with respect to transcription activation from human promoters. Overall, the DRIMER platform is a highly programmable system that allows stoichiometric and combinatorial effector recruitment for precise modulation of human gene expression, which is an attractive capability for a wide range of cell and gene therapy applications.

1053 Characterizing the Phenotypic Abnormalities of a Novel Mouse Model of Snyder-Robinson Syndrome: For Therapeutic Development

Oluwaseun Akinyele[1], Anushe Munir[1], Marie Johnson[1], Megan S. Perez[2], Yuan Gao[1], Foley R. Jackson[3], Yijen Wu[4], Tracy Murray-Stewart[5], Robert A. Casero[5], Bayir Hulya[1], Dwi U. Kemaladewi[1]

[1]Pediatrics, University of Pittsburgh, Pittsburgh, PA,[2]Human Genetics, University of Pittsburgh, Pittsburgh, PA,[3]Sidney Kimmel Comprehensive Cancer Center, John Hopkins School of Medicine, Baltimore, MD,[4]Development Biology, University of Pittsburgh, Pittsburgh, PA,[5]Sidney Kimmel Comprehensive Cancer Center, Johns Hopkins School of Medicine, Baltimore, MD

Background: The polyamines putrescine, spermidine, and spermine are essential molecules for cellular growth processes such as gene expression, signal transduction, and ion channel regulation. Accumulation of spermidine due to mutations in the *SMS* gene, encoding spermine synthase, SMS, causes Snyder-Robinson syndrome (SRS). This rare X-linked recessive disorder, with no available treatment, manifests with a spectrum of symptoms including intellectual disability, developmental delay, seizure, thin habitus, and low muscle tone. Therapeutic development for SRS requires an understanding of the disease pathophysiology in a suitable disease-specific animal model that recapitulates the abnormalities seen in patients. A mouse model carrying a missense mutation in the *Sms* gene resulting in a glycine-to-serine substitution at position 56 (G56S) of SMS protein, was recently generated. This mouse was modeled after patients with a severe form of SRS. Our aim is to characterize the disease manifestation in the G56S mouse as a model for SRS and to study the molecular mechanisms underlying SRS pathogenesis. Similarly, we aim to develop a gene therapy approach for SRS using this mouse. We hypothesize that *Sms* mutation in the G56S mouse leads to abnormal phenotypic signatures that mimic the disease presentation in patients. **Methods and Results**: We performed molecular, behavioral, and neuroanatomic studies to evaluate neurological functions and to understand the pathophysiology of SRS in the G56S mice. We observed a complete loss of SMS protein and elevated spermidine/spermine ratio in the mutant mouse tissues. In addition, the G56S mice had increased anxiety, signs of impaired learning, and decreased explorative behavior, as assessed using fear conditioning, Morris water maze, and open field tests respectively. Furthermore, the mice failed to gain weight over time and exhibited abnormalities in brain structure and bone density on T2-weighted MRI and micro-CT scans respectively. Transcriptomic analysis of the brain cortex of the mutant mice indicates downregulation of genes involved in mitochondrial oxidative phosphorylation and ribosome protein synthesis. Similarly, isolated fibroblasts from the G56S mouse showed impaired mitochondria bioenergetic, suggesting a possible role of impaired mitochondria respiration in disease pathogenesis. **Conclusion**: Our data showed the G56S mouse recapitulates many of the SRS phenotypic abnormalities and revealed key cellular and molecular processes that are altered in the mice that could possibly contribute to the disease pathogenesis. Current experiments focus on the development and evaluation of a gene therapy approach for SRS via viral-mediated expression of the WT *Sms* gene. We anticipate that the successful completion of this study will open the door to a gene therapy approach for SRS and other polyamine-related genetic diseases.

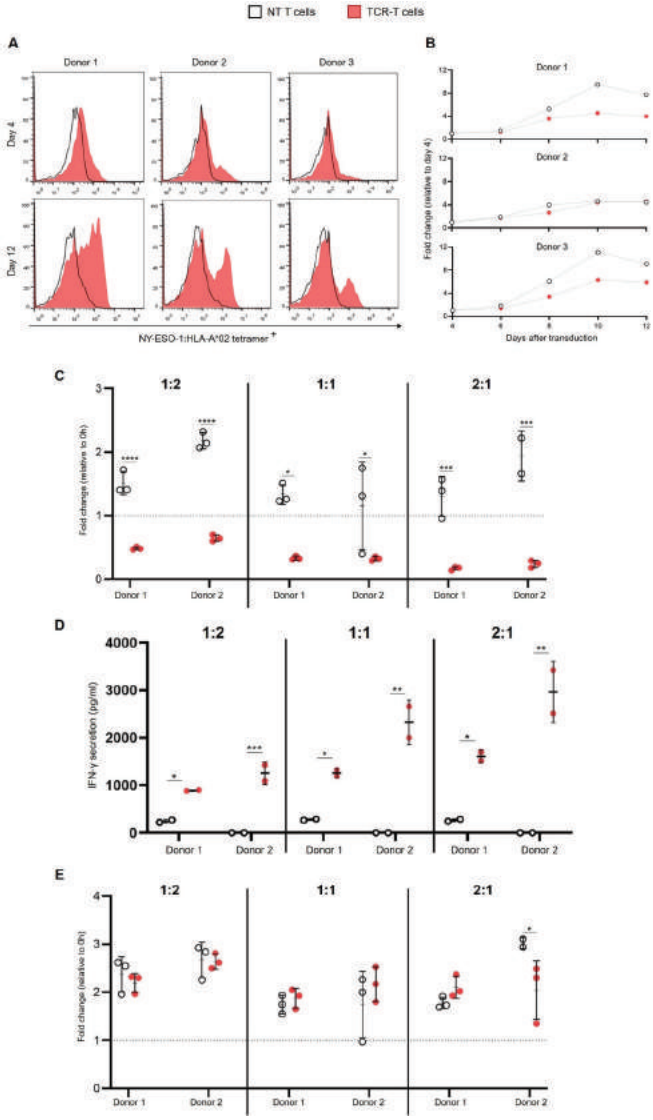
1054 Generation of Genetically Engineered T Cells Expressing Affinity-Enhanced TCR Anti-NY-ESO-1:HLA-A*02 with Potent and Target-Specific Antitumor Activity for the Treatment of Solid Tumors

Rafaela Rossetti[1], Sarah C. G. Lima[1], Daianne M. C. Fantacini[2], Izadora P. Furtado[1], Roberta M. Silveira[1], Heloisa Brand[2], Andreza U. Q. Ferreira[2], Lev Tsyrenov[3], Hiroshi Shiku[3], Lucas E. B. Souza[1], Dimas T. Covas[1]

[1]Blood Center of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil,[2]Butantan Institute, São Paulo, Brazil,[3]Mie University, Mie, Japan

Impressive clinical responses have been achieved in CAR-T cell therapy for hematologic neoplasms. These cells efficiently eliminate tumor cells through the restricted recognition of surface antigens. However, most tumor-associated antigens are intracellular, thereby restricting the application of classical CARs against solid tumors, which represent the vast majority of the neoplasms. To overcome this limitation, T cells engineered to express artificial T cell receptors (TCRs), or TCR-T cells, are able to recognize intracellular proteins presented by the major histocompatibility complex (MHC, or HLA in humans), expanding the options of therapeutic targets. In this context, the NY-ESO-1 is a target that stands out for its restricted expression in healthy tissues (placental and immune-privileged organs) and strong and homogeneous expression in several types of tumors. Thus, the main goal of this study was the generation of TCR-T cells expressing an affinity-enhanced TCR against the NY-ESO-1:HLA-A*02 complex aiming at developing an innovative advanced cell therapy product in Brazil, to be made available through the public health system. To that end, human T cells (3 donors) were transduced with a lentiviral vector for expression of a recently developed new affinity-enhanced TCR targeting the NY-ESO-1:HLA-A*02 complex. The transduction efficiency accessed by labeling with NY-ESO-1:HLA-A*02 specific tetramers was on average of ~17% (± 5.1%) on day 4 and increased ~1.5 times on day 12, reaching an

average of ~25% (± 8.4%) (figure 1A), indicating an enrichment of the T cell population expressing the artificial TCR. In vitro growth kinetics of transduced T cells were similar to that of non-transduced T cells (NT T cells) (figure 1B). Next, cytotoxicity and selectivity of TCR-T cells (2 donors) were evaluated in a co-culture assay with SW982^{luc} cells (human synovial sarcoma cells, NY-ESO-1^{+}, HLA-A*02^{+}) or HCT116^{luc} cells (NY-ESO-1^{-}, HLA-A*02^{+}). TCR-T cells were able to eliminate on average 43%, 68% and 80% of the SW982^{luc} cells after 48h of co-culture in 1:2, 1:1 and 2:1 effector-to-target ratios, respectively (figure 1C). SW982^{luc} tumor cell lysis was accompanied by increased secretion of IFN-γ when compared to NT T cells (figure 1D). Additionally, TCR-T cells had no cytotoxic capacity against HCT116^{luc} cells, demonstrating their target-specific activity (figure 1E). Taken together, these results are promising in view of the development of a new advanced cell therapy product for patients with NY-ESO-1-positive tumors. **Figure 1A**. T cells transduction efficiency. **B**. Cellular proliferation rate. **C.** Co-culture with SW982^{luc} cells (bioluminescence). **D.** IFN-γ secretion after co-culture with SW982^{luc} cells. **E.** Co-culture with HCT116^{luc} cells (bioluminescence). ANOVA, multiple comparisons; *p ≤ 0.05, **p ≤ 0.01, ***p ≤ 0.001, ****p ≤ 0.0001).



1055 Utilizing Surface-Functionalized Nanoneedles for *Ex Vivo* Physical Cargo Delivery into Cells

Lauren Nicole Goetsch, Eldon Thomas Chou, Abtin Tondar

Mekonos, San Francisco, CA

The development of cell and gene therapies can be impacted by deleterious and unintended effects on cells and patients from the current suite of available delivery methods. Fragile cell types are often destroyed during electroporation and fine dosage control is restricted. Strict constraints on cargo size, manufacturing capacity issues and the potential for unexpected deleterious effects within patients make viral vector-based methods also challenging. Microinjecting cells one-by-one is tedious, and the process can often kill cells. Lipid and polymer-based methods have low reproducibility, cytotoxicity issues, low efficiency in many different cell types and cannot support complex or multiplexed cargos. This lack of safe and effective delivery prevents utilizing engineered cells from widespread therapeutic use, despite showing incredible promise in curing previously untreatable diseases. Here we describe the next generation of molecular payload delivery, a novel *ex vivo* method employing an array of engineered silicon nanoneedles on a chip that enables direct intracellular access in a precise, efficient, and automated manner. We pair our nanoneedle technology with an aptamer-based surface chemistry that controls discharge of the desired biomolecule directly into the cell. Our cell engineering platform can deliver precisely to many cells at once and has eliminated many of the issues with the preceding conventional delivery methods. Our nanoneedle delivery approach has displayed positive results with an assortment of cell and cargo types, allowing us the ability to deliver nucleic acids, proteins, and RNP complexes into a range of immortal, stem, and primary cell types with higher viability and efficiency than current industry standard methods. This platform has remarkably exhibited single cell precision at scale, and the ability to multiplex with dosage control. We believe our nanoneedle delivery system will unlock previously unobtainable engineered cell therapies with its uniquely promising capabilities.

1056 AAV Packaging in HEK293 Cells Prefers Unit-Length Vector Genomes

Xin Li[1], Lohra Mickelle Miller[2], Dylan A Frabutt[1], Anh K Lam[1], Benjamin E. Draper[2], Martin F. Jarrold[2], Roland W. Herzog[1], Weidong Xiao[1], Junping Zhang[1]

[1]Indiana University School of Medicine, Indianapolis, IN,[2]Chemistry Department, Indiana University, Bloomington, IN

Recombinant adeno-associated virus (rAAV) is a successful gene therapy vector providing FDA-approved therapies. Generally, AAV has a normal packaging capacity of ~4.7kb, but around 5.3kb genome can also be efficiently packaged. In sf9 cells, full-length and oversize genome has been reported regardless of vector unit length, which leads to the increase sf9-produced vector heterogeneity. Here we systemically investigated if non-unit length packaging AAV genomes occurs in HEK 293 cells. First, four vector plasmids containing rAAV genome with a size of 848bp (AAV8-TTR-coFVIII-848), 1320bp (AAV8-TTR-coFVIII-1320), 2981bp (AAV8-TTR-coFVIII-2981) or 4707bp (AAV8-TTR-coFVIII-4707) were used for vector production in the

presence of a helper plasmid (pFΔ6, encoding adenovirus E4, E2A and VA) and a Rep-Cap plasmid (pH28) into suspension HEK293 cells to make rAAV8 vectors. The vectors were purified by iodixanol gradient ultracentrifugation. The resulting vector particles were analyzed using charge detection mass spectrometry (CD-MS). Interestingly, peak fractions of both AAV8-TTR-coFVIII-848 and AAV8-TTR-coFVIII-1320 vector preparations are either empty particles or particles with varying amounts of unit-length genomes. There was a positive correlation between vector mass weight and its genome size (r=0.999); In contrast, vectors from AAV8-TTR-coFVIII-2981 and AAV8-TTR-coFVIII-4707 showed only empty particles and the full particles containing a single unit length genome. There was a broader distribution of partial particles in AAV8-TTR-coFVIII-4707 vector preparations, and no oversized packaging of unit length genome was observed. Alkaline agarose gel electrophoresis data indicates the that the AAV8-TTR-coFVIII-848 vector packaged DNA distributions at sizes 848, 1696, 2544, 3392, 4240 and 5088bp. In addition, the AAV8-TTR-coFVIII-1320 vector the packaged DNA distributions at sizes 1320, 2640, 3960 and 5280bp indicating that this kind of shorter AAV genome was packaged in a unit-length DNA ligation way. In contrast, the AAV8-TTR-coFVIII-2981 and AAV8-TTR-coFVIII-4707 vectors showed a single band at the corresponding unit length vector genome. These results demonstrated that AAV packaging in HEK293 cells has a preference for encapsidating a genome close to its maximal capacity by packaging multiple unit-length genomes when unit-length genome is very small, in contrast, non-unit length genome packaging was inhibited. Taken together, AAV packaging behavior in HEK 293 cells is different from what has been reported in sf9 cells. There might exist different packaging mechanisms between the two types of cells.

1057 Gene Activation Mediated by Zinc Finger Transcriptional Regulators (ZF-TRs) as a Therapeutic Approach for CNS Disorders

Siavash Fazel Darbandi, Dan Chung, Esme Ponce, Bob Radeke, Jisoo Lee, Jason Eshleman, Sarah Hinkley, Alicia Goodwin, Patrick Dunn, Alaric Falcon, Toufan Parman, Gregory Davis, Bryan Zeitler, Andrew Young, Amy Pooler

Sangamo Therapeutics, Inc., Richmond, CA

Neurodevelopmental disorders are impairments of the development of the brain and/or central nervous system (CNS) that affect emotion, learning ability, self-control, and memory. The development of the nervous system is tightly regulated and is influenced by both genetic and environmental factors. Some neurodevelopmental disorders are considered multifactorial syndromes which have many causes that converge to a more specific neurodevelopmental manifestation in forms of haploinsufficiency. At Sangamo Therapeutics, we are utilizing our proprietary zinc finger transcriptional regulator platform (ZF-TR) to upregulate gene expression by tethering zinc fingers to a trans-activation domain. Here we demonstrate target upregulation at mRNA and subsequently protein levels *in vitro* (mouse cortical neurons and CDI human iPSC-derived neurons) and *in vivo* (wildtype mouse). We successfully demonstrated *in vitro* to *in vivo* translatability by injecting our zinc finger activators to wildtype mice. Thus, Sangamo's zinc finger activator platform could be utilized to potentially alleviate reduced levels of functional proteins in neurodevelopmental disorders caused by haploinsufficiency.

1058 Temsirolimus and IL-7 Treatment Synergistically Increase Primary Resting CD8+ T Cell Transduction with CD8-Targeted Fusosomes and Enhance CD19CAR Expression

Hadega A. Aamer, Mariliis Ott, Daryl Humes, Brian Dolinski, Christina Proano, Ryan White, Ashley Benson, Diana Vedenova, Kutlu Elpek, Semih U. Tareen, Neal Van Hoeven

Sana Biotechnology, Seattle, WA

Introduction: Resting human T cells are difficult to transduce with lentiviral vectors (LVV) primarily due to blocks imposed by cellular restriction factors during viral replication. These blocks collectively limit the potency of LVV-based T cell gene therapies. While restriction factors have been extensively studied in CD4+ T cells infected with HIV-1, the impact of these proteins in CD8+ cells is not as well-described. We investigated the role of known restriction factors in limiting targeted lentiviral vector (fusosome-LVV) mediated transduction in primary CD8+ T cells and have found that IFITM1 and SAMHD1 impose potent blocks in this cell type. Mechanistically, IFITM1 impedes LVV fusion at the cell membrane while SAMHD1 interferes with reverse transcription by cleaving cellular dNTPs and reducing available nucleotide pools. We hypothesized pharmaceutical intervention(s) that have been shown to inactivate these restriction factors may increase potency, potentially reducing the minimal efficacious dose of fusosome-LVV. Previous data have shown that IFITM1 can be downregulated by pre-treating resting T cells with rapamycin, while IL-7 pre-treatment can lead to enhanced levels of the inactive form of SAMHD1 (pSAMHD1). Having identified both factors as being potent restriction factors in CD8+ T cells through restriction factor knockout experiments, we developed an optimized combination treatment including IL-7 and temsirolimus (TEM), a rapamycin analog (rapalog), that dramatically improves gene delivery efficiency and downstream efficacy of our CD8-targeted fusosome-LVVs *in vitro*, thus demonstrating that overcoming restriction factors in cell and gene therapy may enhance the efficacy of these viral vectors.
Methods/Results: Resting pan-T cells from multiple donors were pre-treated for 3 days with IL-7 or IL-2 as a control. Cells were then incubated with TEM for 2 hours before a 2-hour transduction with a

range of CD8-targeting fusosome-LVV delivering GFP or CD19CAR transgenes. Cells were washed and left in IL-2/IL-7 containing media for 1 day before CD3/CD28 activation. Six days later, cells were analyzed by FACS for GFP or CAR expression. CAR T cell function and ability to kill Nalm6 tumor cells was also assessed. The combination of TEM and IL-7 pre-treatment led to the greatest dose-dependent increase in transduction efficiencies in resting T cells in all donors as measured by FACS with higher CD19CAR or GFP expression observed with IL-7+TEM compared to IL-2+TEM treatment. Furthermore, IL-7 and TEM synergistically improved transduction efficiencies and GFP expression up to 11X compared to cells incubated with either component alone. Varying the pre-treatment IL-7 dose did not lead to dose-dependent differences in transduction efficiencies by FACS. Western blot analysis of IFITM1 and pSAMHD1 protein levels highlight a specific effect of combination treatment on relevant restrictions factors; a pronounced loss of IFITM1 protein expression after 2 hours of TEM treatment and an increase in pSAMHD1 levels after 3 days of IL-7 pre-treatment was observed across multiple donors. **Conclusions:** Our findings identify key restriction factors that limit transduction by our CD8-targeted fusosome-LVVs and show that potency is significantly increased in resting T cells following IL-7 and TEM treatment in a transgene-independent manner. This increase in potency is consistent with the inactivation or loss of two critical restriction factors, SAMDH1 and IFITM1, as demonstrated by western blot analysis. Collectively, these results suggest a strategy toward a combination *in vivo* vector-based therapy that is supplemented with pharmaceutical agents to improve vector potency.

1059 Multiplex Knockdown of ANGPTL3 and CYPOR as a Novel Treatment for Familial Hypercholesterolemia

Ilayda Aytes[1], Callie Stuart[1], Sarah Minich[1], Mugdha Padalkar[2], Olga Savinova[3], Jing Echesabal-Chen[4], Alexis Stamatikos[4], Renee N. Cottle[1]

[1]Department of Bioengineering, Clemson University, Clemson, SC,[2]Department of Biomedical Sciences, New York Institute of Technology, Long Island, NY,[3]Department of Biomedical Sciences, New York Insititute of Technology, Long Island, NY,[4]Department of Food, Nutrition, and Packaging Sciences, Clemson University, Clemson, SC

Familial hypercholesterolemia (FH) is a genetic disorder characterized by elevated low-density lipoprotein cholesterol (LDL-C) resulting in premature atherosclerotic cardiovascular disease. The knockdown of ANGPTL3 using CRISPR-Cas9 gene editing has been explored as a novel approach for treating FH. Ex vivo gene editing is potentially safer than in vivo approaches to treat genetic diseases affecting the liver. Still, low engraftment by gene-edited hepatocytes after transplantation poses a challenge for this ex vivo strategy. By knocking down NADPH-cytochrome P450 oxidoreductase (CYPOR) followed by treatment with APAP, a selective advantage is given to gene-edited cells after transplantation. A novel gene editing approach for treating FH includes isolating hepatocytes from the patient's resected liver, editing hepatocytes ex vivo with Cas9 and Cas12a systems to knock down ANGPTL3 and CYPOR, and transplanting the gene-edited cells back into the patient. This procedure would be followed by transient APAP administration to select edited cells in vivo. In contrast to Cas9, multiplex gene editing using the Cas9/Cas12a system will reduce the potential for chromosomal rearrangement. Here, we optimize multiplex gene editing for Angptl3 and CYPOR using both dual Cas9 and Cas9/Cas12a systems in Hepa1-6 cells and primary mouse hepatocytes. In preliminary in vivo experiments, we delivered *Cypor*-targeting plasmid via hydrodynamic injection and treated the mice biweekly with APAP to produce an ALT elevation >1000 IU/L. After repeated injections, the ALT decreased to normal levels in the experimental group. This decrease indicated the successful selection and expansion of APAP-resistant *Cypor*-deficient hepatocytes. We achieved an average of 45% *Cypor*-knockdown in the livers of APAP-selected C57bl6 mice. Next, we delivered *Cypor*-targeting Cas9 RNPs to hepatocytes ex vivo via electroporation and transplanted the edited hepatocytes into C57bl6 mice. When the APAP selection process was repeated, we observed an ALT peak followed by a decrease. At the end of the experiment, we observed an average engraftment of 15% in the experimental mice compared to 2% in the control and no indications of liver failure. In Hepa 1-6 cells electroporated with *Angptl3*- and *Cypor* - aiming Cas9 RNPs, we observed 83% and 92% indels for *Angptl3* and *Cypor,* respectively. In Hepa1-6 cells electroporated with *Cypor*-aiming Cas9 RNPs combined with *Angptl3*-aiming Cas12a RNPs, the optimized condition resulted in 78% and 90% indels for *Angptl3* and *Cypor*, respectively. **Conclusion** Our findings suggest that *Cypor* knockout followed by APAP treatment is a promising method to select for the gene-edited hepatocytes. Moreover, this selection method could be successfully combined with an electroporation-mediated ex vivo gene editing strategy. This study also provided preliminary data showing multiplex delivery of Angtpl3- and Cypor-aiming sgRNA with Cas proteins offers high levels of gene editing in a cell line using both a dual Cas9 and Cas9/Cas12a system. In future studies, we will demonstrate proof-of-principle multiplex editing to knock down *Cypor* and *Angplt3* combined with APAP selection for reversing atherosclerosis in Ldlr-/- mice and evaluate the safety of dual Cas9 and Cas9/Cas12a multiplex gene editing.

1060 Improved Differentiation Efficiency and Proliferation Ability of NK Cells from Cord Blood HSCs by Hyperosmosis

Wei Wen[1], Xinyu Sun[1], Xiang Chen[2], Fengqi Fang[2], Xinyi Shen[3], Huayi Li[3], Feng Zhang[1], Jianping Zhang[1], Xiaobing Zhang[1]

[1]State Key Laboratory of Experimental Hematology, Haihe Laboratory of Cell Ecosystem, Institute of Hematology & Blood Diseases Hospital, Peking Union Medical College, Tianjin, China,[2]Department of Oncology, The First Affiliated Hospital of Dalian Medical University, Dalian, China,[3]College of Computer Science and Technology, China University of Petroleum (East China), Qingdao, China

Natural killer (NK) cells are cytotoxic innate lymphoid cells with great potential for immunotherapy. Engineered NK cells to express a CAR are an alternative immunotherapeutic strategy to CAR-T cells for cancer treatment. NK cells from PB cells can only be expanded hundreds or thousands of times, and this drawback can be overcome by stem cell-derived NK cells. iPSC-derived NK cells (iPSC-NK) are a potential source for CAR-NK cells, but it takes several months for gene modification, clone selection, and directed differentiation. Here we show that cord blood hematopoietic stem and progenitor cells (HSPCs) can be expanded and differentiated into a large number of

HSC-NK cells in less than four weeks. We developed a protocol that includes differentiation of HSPCs on OP9 feeder cells transduced with human DLL1 and DLL4 with high osmotic pressure. Hyperosmosis can be achieved by adding NaCl or PBS to the medium. **Results:** Compared with normal osmotic pressure (300 mM), the high osmotic pressure of 330 mM significantly increased the efficiency of NK cell differentiation (**Figure 1**). Further expansion on the K562-mb21 feeder led to a greater purity of $CD3^{-}CD56^{+}$ NK cells from HSC-NK than that of PB-NK cells. In addition, high osmotic pressure-primed HSC-NK cells showed enhanced proliferative activity with 1.8×10^{6}-fold total expansion and an 11-fold increase in total yield compared to the control (**Figure 2**). Of interest, we found that activating receptors, such as CD69, NKp30, and NKp44, were significantly increased in HSC-NK-300 mM or HSC-NK-330 mM cells compared with PB-NK cells. RNA-seq analysis showed that HSC-NK cells expanded under normal or high osmotic pressure were virtually indistinguishable. Furthermore, the antitumor activities of HSC-NK cells against HepG2 hepatocellular carcinoma cells, MOLM-13 AML cells, and SKOV-3 ovarian cancer cells were comparable to or moderately greater than the PB-NK cell control. Together, hyperosmosis-induced HSC-NK cells are similar to expanded PB-NK cells in phenotype, transcriptome, and killing activities against tumor cell lines. **Conclusions:** Our study supports the possibility of the high-yield generation of NK cells for clinical therapy. Together with lentiviral or CRISPR-mediated CAR integration, our approach will generate sufficient CAR-NK cells from one cord blood for hundreds, even thousands of patients in one month. The finding of hyperosmosis-facilitated NK cell differentiation should find applications in the iPSC-NK generation.

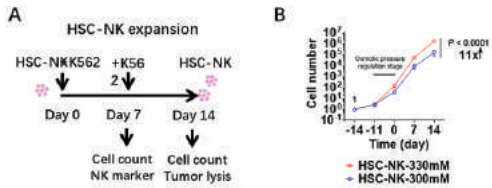

Figure 2. High osmotic pressure-primed HSC-NK cells show enhanced proliferation activity.

1061 Unconstrained Mitochondrial DNA Base Editing Enables Precise Disease Modeling

Santiago R. Castillo[1], Brandon W. Simone[2], Karl J. Clark[3], Stephen C. Ekker[3]

[1]Department of Molecular Medicine, Mayo Clinic, Rochester, MN,[2]Center for Cellular Immunotherapies, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA,[3]Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN

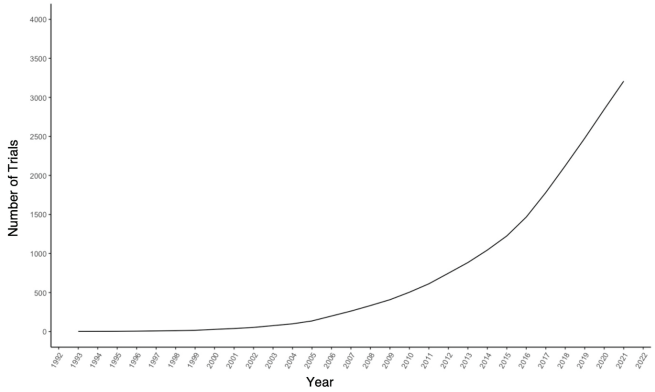
The human mitochondrial genome is a 16,569 bp long, multicopy, circular double-stranded DNA (dsDNA) molecule that encodes 37 genes essential for cellular energy metabolism. Pathogenic mitochondrial DNA (mtDNA) variants are prevalent in ~1 in 8,000 people and are causal in incurable metabolic disorders. Current mtDNA editing strategies rely on all-protein systems, such as transcription activator-like effector (TALE)-based technologies. In general, these technologies are composed of a TALE, which acts as a programmable DNA-binding domain, fused to an effector domain. In particular, dsDNA deaminase A (DddA)-derived cytosine base editors (DdCBEs) consist of TALE-$DddA_{tox}$ fusions. Given its preference for dsDNA, $DddA_{tox}$, the deaminase domain of DddA, is split into two inactive halves to avoid toxicity. Thus, a DdCBE monomer incorporates either the N- or C-terminus of split $DddA_{tox}$ downstream of a TALE. In the context of DdCBE pairs, binding of their respective DNA-binding domains to adjacent target sequences enables the reassembly of functional $DddA_{tox}$, followed by targeted cytidine deamination. Then, uracil glycosylase inhibitors positioned downstream of the split $DddA_{tox}$ halves impede the excision of the resulting uracil residues. Subsequently, U•G intermediates are resolved into T•A base pairs during mtDNA replication, which occurs even in post-mitotic cells. This process results in programmed C•G-to-T•A conversions in mtDNA. Despite their flexibility and robustness, the versatility of canonical DdCBEs is limited by the requirement of a thymine immediately upstream of their respective TALE target sequences. This double 5'T constraint (one per DdCBE monomer) can be difficult or impractical in certain contexts. Based on our previous work on the FusX TALE Base Editor, a platform for the rapid design and assembly of mitochondrial base editors, we generated improved DdCBEs that bypass the 5'T requirement. First, seeking to characterize the activity and specificity profiles of improved DdCBEs relative to their canonical counterparts, we generated DdCBE pairs that target sequences preceded by 5'T or 5'V (V = A, C, G) in both canonical and improved formats. Hence, for a single locus, we tested four DdCBE pairs: a canonical or improved 5'T-compliant pair, and a canonical or improved 5'T-uncompliant pair. We chose four mtDNA loci to test this strategy: *MT-ATP6*, *MT-CO1*, *MT-ND2*, and *MT-ND4*. Thus far, we have not observed significant differences between the activities of 5'T-compliant canonical vs. improved DdCBEs. Additionally, utilizing improved DdCBEs, we installed the pathogenic m.3242G>A variant with no bystander editing at the *MT-TL1* locus in HEK293T cells, demonstrating their potential for precise mitochondrial disease modeling. In summary, we are evaluating the efficiency and specificity of improved DdCBEs that bypass the 5'T requirement, which will support unconstrained mtDNA base editing as a strategy for disease modeling and gene therapy applications.

1062 Estimating Probability of Success of Gene and Cell Therapy Development Programs

Magdi Elsallab[1], Michelle Ouvina[2], Florence Bourgeois[1]
[1]Harvard-MIT Center for Regulatory Science, Harvard Medical School, Boston, MA,[2]Boston Children's Hospital, Harvard Medical School, Boston, MA

Introduction: Gene and cell therapies (GCTs) are a rapidly growing class of pharmaceuticals that have emerged over the past two decades and have shown to hold particular promise for rare diseases and other conditions with unmet medical needs. Despite their therapeutic potential, the development of GCTs faces a number of unique challenges related to complex manufacturing and regulations, as well as exceptionally high costs. An increased understanding of development pathways and clinical trial trajectories could support increased efficiencies and improved forecasting of research and development costs. Here, we analyze the clinical development landscape of CGTs to provide the overall success rates and unravel favorable features that increase the probability of success. **Methods:** We used AdisInsight, a pharmaceutical intelligence database, to identify all clinical trials of GCT products entering commercial clinical development worldwide between January 1990 and July 2022. GCT products were identified through the hierarchal search function of the database. We defined a development path as testing a product in a specific indication. Therefore, a single trial can constitute multiple development paths if multiple indications were tested. To estimate a product's probability of success (POS) in reaching marketing approval in any jurisdiction, we used previously developed methods and modeled a product's development pathway using imputation to estimate missing trial phases (Wong C. H., et al., (2019), Biostatistics). A development program was considered terminated if the time elapsed after the conclusion of the clinical trial was 360 days for phase I, 540 days for phase II, and 900 days for phase III and no trial in the next phase has started. To estimate the change in POS over time, we performed a competing risk analysis, using the time from initiation of clinical development to approval or termination (Putter, H., et al., (2007), Statist. Med.) **Results:** There were 3369 clinical trials that represented 4386 development paths for 1311 GCT products starting commercial development between 1993 and 2022 (Fig.1). 50 (3.8%) GCT products were approved worldwide for 64 indications. Most trials were phase I or phase I/II, with phase III constituting less than 10% of the conducted trials. The majority of trials studied oncology indications, followed by cardiology and endocrinology. On average each product was tested in 3 indications, while oncology products were tested on average in 4 indications. The overall POS for GCT products from phase I to approval was less than 5%. We observed that the use of regulatory incentives such as orphan designation and fast-track increased the POS. Considering POS as a function of time, POS peaked at 15 years after initiation of clinical development with most program terminations occurring in the first 5 years. **Conclusion:** There has been a rapid increase in clinical trials evaluating potential GCT therapies over the past decade. Several trial features, including the use of regulatory incentives, appear to be associated with higher POS and may represent important considerations in designing GCT development programs and guiding early decisions.

Figure 1: Cumulative increase in clinical trials for gene and cell therapies, 1993-2022



1063 AI-Driven Design of RNA-Based Gene Control Systems

Matthew Dale, Birt Jessica
Concinnity Genetics, Edinburgh, United Kingdom

Gene therapies that suffer from clinical holds and failures often cite off-target effects, where the therapy is active in unintended tissues, as a major reason. The FDA has recently highlighted issues of adverse off-target effects in tissues including the liver, kidney and motor neurons. As such, the cell selectivity of gene therapies is becoming increasingly important. Although technologies such as synthetic promoters and tropic vectors have addressed some of the major safety concerns, effective control systems remain difficult to build, with development involving extended trial-and-error processes with no guarantee that an effective control system will be produced. We are developing RNA-based gene control systems to control the activity of cell and gene therapies in a defined manner. Our approach will enable the control of therapeutic activity in response to various conditions (e.g. cell/tissue type, disease, cell differentiation), including FDA approved small molecule drugs, which is typically not possible with current generation cell and gene therapies. Our control systems are RNA sequences that form part of the cell/gene therapy cassette and, in contrast to other control systems, require no additional molecular machinery, avoiding associated complications such as increased immunogenicity, unpredictability of therapeutic efficacy/safety, and poor translation of animal data into humans. Notably, existing control systems only respond to a handful of inputs with limited commercial utility, and building systems that respond to new commercially relevant inputs is very difficult. Current methods are highly inefficient, requiring the testing of 100,000s of candidate sensors while only covering <1 billionth of the design space. Our AI-led design process can explore the design space in a more intelligent and controlled manner, reducing the required amount of testing >10-fold and massively increasing success rates. Our high-throughput experimental platform provides incredibly information-dense data in a highly parallelised manner while requiring minimal time and resources to perform, allowing us to test control system candidates at scale and rapidly identify promising candidates. We are currently using these methods to develop disease and tissue specific control systems. The key benefit of this approach is that the resulting control systems are therapeutic agnostic and can be incorporated into any type of gene therapy, including cell and RNA

therapies, and are compatible with all delivery mechanisms. This approach will improve safety and efficacy by reducing the likelihood of adverse effects and allowing active control of dosage, thereby enabling refined clinical management and monitoring.

1064 Healthcare Utilization, Burden of Illness, and Mortality in Adults with Adrenomyeloneuropathy: The Case for Genetic Therapies

Florian Eichler[1,2], Josh Bonkowsky[3,4], Bridget Healey[5], Naomi C. Sacks[5], Ronae K. McLin[5], Philip Cyr[5], Eileen Sawyer[6], Christopher D. Stephen[1,2]

[1]Department of Neurology, Massachusetts General Hospital, Boston, MA,[2]Harvard Medical School, Boston, MA,[3]Primary Children's Hospital, Intermountain Healthcare, Salt Lake City, UT,[4]Division of Pediatric Neurology, Department of Pediatrics, University of Utah School of Medicine, Salt Lake City, UT,[5]Heath Economics and Outcomes Research, PRECISIONheor, Boston, MA,[6]Clinical and Medical Affairs, SwanBio Therapeutics, Boston, MA

Background: Adrenomyeloneuropathy (AMN) is an X-linked neurodegenerative disease caused by mutations in *ABCD1* resulting in progressive myeloneuropathy that causes spastic paraparesis, sensory ataxia, loss of mobility, incontinence, and sexual dysfunction. Disease onset is earlier in men compared to women who are heterozygous for the disease. The burden of illness and impact on healthcare resource utilization (HRU) have yet to be described. We quantified HRU, clinical characteristics, and mortality in adults with AMN in the US. **Design/Methods**: HRU was assessed using commercial insurance claims from IQVIA's PharMetrics Plus database (1/01/2006-6/30/2021). AMN patients were 18-64y with ≥1 inpatient or ≥2 outpatient claims containing an AMN diagnosis (ICD-10-CM: E71.52x; ICD-9-CM 277.86), no evidence of childhood cerebral adrenoleukodystrophy, other peroxisomal disorders, or pregnancy/labor or delivery. AMN patients were propensity score matched to non-AMN individuals on demographic characteristics. Patients were followed for as long as they were observable. Separately, mortality rates and age at death were assessed in the Medicare Limited Dataset (1/01/2017-03/25/2022) for AMN patients and compared with all beneficiaries.**Results**: We identified 806 commercially insured AMN patients with a mean age of 35.0 ±12.44y, followed for an average 22.7±23.55 months. AMN patients had more inpatient admissions (0.30 vs. 0.05); outpatient clinic (10.64 vs. 5.54), outpatient hospital (4.65 vs. 1.19), and home healthcare visits (2.88 vs. 0.21); more durable medical equipment claims (0.52 vs. 0.10); and more prescription medications (18.36 vs 7.84 pharmacy fills) per patient per year than non-AMN controls. Hospital length-of-stay (8.23 vs. 4.89 days) was also longer in AMN patients. All reported HRU comparisons were statistically significant, $p<.05$. Comorbidities were more common in AMN compared to controls, including peripheral vascular disease (3.1% vs. 0.6%), chronic pulmonary disease (6.1% vs. 3.2%), and liver disease (4.1% vs. 0.8%), all $p<.05$. Comparing AMN with controls throughout - mortality rates among younger (ages 18-64y) AMN Medicare enrollees were 5.3x higher among males (39.3% vs. 7.4%) and 3.2x higher among females (15.7% vs. 4.9%), both $p<.001$. Age at death was significantly younger for male AMN patients 18-64y (47.0±11.3 vs. 56.5±7.8, $p<0.001$). Among AMN patients ages ≥65y, mortality rates were 2.2x higher for males (48.6% vs. 22.4%) and 1.5x higher for females (31.2% vs. 20.3%), both $p<.001$. **Conclusions**: AMN imposes a substantial and previously under-recognized health burden for adults with men affected earlier and more severely than women, including greater medical comorbidities, higher healthcare utilization, higher mortality rates, and, in some subgroups, younger age at death. The high unmet need and genetic disease burden calls for disease-modifying interventions and points to the value in developing targeted genetic therapies.

Patient Demographic and Clinical Characteristics

Characteristics	Cases (AMN) n = 806	Controls (Non-AMN) n= 2726

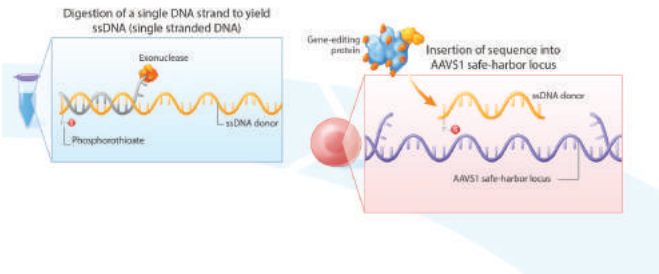
1065 Chemically Modified Single-Stranded DNA Donors Enable Efficient mRNA Gene Editing-Mediated Knock-In in Human iPS Cells

Claire Aibel, I. Caglar Tanrikulu, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

Genome-editing technology provides a means of modifying genes in living cells, and is being explored for the development of therapies to treat cancer and a variety of genetic disorders. Gene-editing proteins can be used to create single- and double-strand breaks at specific genomic sites for knocking out a gene or, when combined with an exogenous DNA donor, knock-in of a defined sequence. Compared with double-stranded DNA (dsDNA), single-stranded DNA (ssDNA) exhibits lower toxicity and is less prone to random genomic integration, making it an attractive form of DNA donor for gene knock-in. However, current methods of synthesizing ssDNA, including enzymatic digestion, asymmetric PCR, and chemical synthesis, suffer from low yields, contamination with residual dsDNA, length limitations, and high cost. Here, we present an enzymatic approach for producing long (>3kb) and concentrated (>1μg/μL) ssDNA suitable for generation of knock-in lines of human induced pluripotent stem (hiPS) cells. We PCR-amplified dsDNA from plasmid templates using 5'-modified primers incorporating a 5' phosphate on the strand intended for digestion and a single 5' phosphorothioate linkage on the protein-

encoding strand to protect against digestion. The resulting PCR products were treated with lambda exonuclease, which preferentially digests strands with a 5' phosphate group, to yield a single-stranded product. To minimize degradation of the ssDNA, we included in the reaction a short, double-stranded oligonucleotide (dsDecoy), for which lambda exonuclease has higher affinity than ssDNA. Reactions were further treated with the less processive T7 exonuclease to eliminate residual dsDNA not digested by lambda exonuclease, yielding concentrated (>1μg/μL) ssDNA. Gel electrophoresis analysis of five products ranging from 1.4kb to 3.3kb revealed a single, sharp band in the region of interest. Four of the ssDNA products contained less than 0.3% residual dsDNA by mass, as determined by gel electrophoresis using a double-stranded standard of known concentration. The fifth, 3.3kb ssDNA product contained 1.1% dsDNA by mass. To test their utility as knock-in donors, ssDNA products were co-electroporated into hiPS cells with mRNA encoding UltraSlice gene-editing proteins targeting the AAVS1 safe harbor locus. Insertion efficiencies were 67.8% for a 1.2kb donor, 8.6% for a 2kb donor encoding a ROR1 CAR, and 2.7% for a 2.8kb donor encoding green fluorescent protein. In summary, we demonstrate a method for high-yield synthesis of ssDNA suitable for cellular applications, including mRNA gene editing-mediated knock-in in iPS cells. Overall, this platform may prove useful in the development of gene-editing therapeutics.



1066 Performance and Modularity of Horizon's Pin-point™ Base Editing System Characterized by Arrayed and Pooled Screening Platforms

Paul Russell[1], Jennifer Harbottle[1], Steve Lenger[2], Jesse Stombaugh[2], Alexander Hale[1], Leah Nantie[2], Hidevaldo Machedo[2], Immacolata Porreca[1], Pablo Perez-Duran[1], Anja Van Brabant Smith[2], Michael Rushton[1]

[1]Horizon Discovery, Waterbeach, Cambridge, United Kingdom,[2]Horizon Discovery, Boulder, CO

Base editing is a CRISPR-Cas-based technology that allows the introduction of point mutations in the DNA without relying on double strand break formation. Hence it is becoming a strong contender in the development of innovative cell and gene therapies. Horizon's Pin-point base editing technology utilizes an RNA aptamer embedded within the sgRNA to enable the recruitment of a cytidine deaminase for highly efficient and precise nucleotide conversion. The resultant modularity of the platform enables a high degree of flexibility that allows fine tuning of critical aspects of editing behavior, including efficiency, window size and position, and nucleotide context preference. Such adaptability of the system is critical to realize the huge potential of base editing for the generation of cell and gene therapies. In this study, we report the development of arrayed and pooled screening platforms to provide comprehensive characterization of editing performance and to assess guide RNA functionality in a high-throughput manner. Firstly, we describe an arrayed screening platform using five different cytidine deaminases and three structurally distinct tracrRNAs, and assess functionality of Pin-point system architecture at 70 guide-specific genomic sites. We demonstrate significant impact upon editing behavior with different deaminases. Secondly, we present a flexible and adaptable pooled screening reporter platform for high-throughput parallel assessment of >65,000 gRNAs, including 7009 guides targeting pathogenic SNVs. We demonstrate the ability of the pooled screening platform to detect editing in a highly reproducible manner. In summary, we present the Pin-point platform as a tunable, modular system that can be readily adapted to address diverse editing requirements.

1067 Deconvolution of Clinical Variance in CAR-T Pharmacology and Response Using a Mathematical Model of T Cell Differentiation Control

Daniel Kirouac[1], Cole Zmurchok[1], Avisek Deyati[1], Jordan Sicherman[1], Chris Bond[2], Peter Zandstra[3]

[1]Systems Biology, Notch Therapeutics, Vancouver, BC, Canada,[2]Notch Therapeutics, Seattle, WA,[3]University of British Columbia, Vancouver, BC, Canada

CAR-T cell expansion and persistence varies widely between patients and is predictive of efficacy. To understand the mechanisms underlying this variance, we developed a mathematical description of T cell regulatory control wherein transitions between memory, effector, and exhausted T cell states are coordinately regulated by antigen engagement. The model was trained using clinical data from CAR-T products in different hematological malignancies (Kymriah and Abecma) and identified cell-intrinsic differences in the turnover rate of memory cells and cytotoxic potency of effectors as the primary determinants of exposure and response. These mathematical inferences were confirmed using bulk and single cell RNAseq data, and population exposure and response predictions validated against registrational data from Kymriah and Yescarta. Using a machine-learning workflow we demonstrate that product-intrinsic differences can accurately predict patient outcomes based on pre-infusion transcriptomes, while additional pharmacological variance arises from cellular interactions with patient tumors. We find that transcriptional signatures outperform T cell immunophenotyping as predictive of clinical response for two CD19-targeted CAR-T products in three indications (CLL, ALL, and LBCL). We describe a "CAR T cell response scorecard" that can be referenced to characterize the transcriptomes of post-manufactured products and more reliably predict patient responses. Combined with our pharmacology modelling workflow, these methods will enable a new phase of therapeutic T cell development, including the use of alternate sources such as induced pluripotent stem cells.

1068 Enhanced Gene Editing by Coiled-Coil Recruitment of an Exonuclease to CRISPR/Cas

Duško Lainšcek
National Institute of Chemistry, Ljubljana, Slovenia

The CRISPR/Cas system is a highly potent tool which has revolutionized genome engineering and regulation of gene transcription in various cells and organisms. This gene-editing tool consists of a guide RNA (gRNA) and Cas9 endonuclease. Cas9 catalyzes the formation of double-strand DNA breaks, which are then repaired by different cell mechanisms. Error-prone Non-homologous end joining occurs, resulting in random indel (insertion-deletion) mutations, which can lead to functional gene inactivation by either frameshift or deletions. To achieve greater indel mutations that can lead to bigger gene disruption, CRISPR system can be coexpressed in cells with DNA exonucleases, which cause increased recessions of DNA following DNA breaks. We show that joint action of the CRISPR system with different exonucleases significantly increases the percentage of indel mutations at various targeted genes. Of the different exonucleases tested, the *E.coli*-derived exonuclease III (EXOIII) exhibited the best performance in terms of indel formation. To further improve the rate of indel mutations, Cas9 and EXOIII were brought into the proximity via coiled-coil forming heterodimeric peptides (CCExo). This resulted in increased indel formation compared to the classical CRISPR/Cas system as well as more efficient than cointroduction of non-interacting and genetically fused Cas9-EXOIII. We discovered that not only the percentages of indel were increased also the size of gene deletions were significantly enhanced compared to conventional CRISPR/Cas system. Genome editing rate was augmented when using heterodimeric coiled-coil forming peptides with higher binding affinity. By high through put method, called CIRCLE-seq we have proven that increase in genome modification does not bare any dangers as no additional undesired DNA cleavage was observed. The robustness of CCExo was determined for different genes in various cell lines, as well in human primary cells and in somatic adult cells. Finally we performed a case study for the use of the CCExo system as a potential anti-cancer therapeutic tool. The Philadelphia chromosome, which occurs in leukemic cancer cells, is the result of characteristic the reciprocal genome translocation t(9:22) and is responsible for higher proliferation of tumorous cells. Using the CCExo system, we achieved a higher degree of indel mutations at the translocation site, which resulted in greater killing of cancer cells, thus providing a useful potential anti-cancer therapeutic tool. This was also confirmed *in vivo* by using xenograft animal cancer model. We successfully confirmed that enhanced genome editing tool, CCExo, holds a tremendous potential not only in treating CML cancer but potentially also in other diseases with genetic etiology.

1069 Exploring Innovative Methods for Enhancing Lentiviral Vector Yield and Target Cell Infectivity in CAR-T Cell Therapy Manufacturing

Hannah Munkacsi, Chih Hong Lou
Theragent Inc., Arcadia, CA

In recent years, labs and companies have been seeking ways to reduce the cost of manufacturing CAR-T products to increase the accessibility of the CAR-T treatment. Advances in cell processing and manufacturing techniques have improved in recent years. Along with technology improvements, the viral vector lab are continuously exploring novel methods for enhancing the efficiency and the quality of the procedures in the CAR-T manufacturing and it have been shown as successfully achieved. First, our lab has developed several new viral production cell lines and modified traditional transduction method for the viral production and cell modification. By using the newly developed production cell line, the yield of the viral vector can be significantly increased at least 5 folds in unprocessed viral titer comparing with the traditional adhering method and additional, at least, 25% of the production yield comparing with the current market available suspension culture lines. In addition, using the modified cell line, we found that the capacity of the gene insertion size in the testing viral transfer plasmid can be significant increased into 6~8 KB CDS length while maintaining its related production titer. It provides more flexibility in the vector design. Our lab has also developed a method that enables improved the infectability of cells using a significantly lower viral MOI during the CAR-T development process. With the designed drug treatment, treated cells can be sensitized for infection with 3 folds lower MOI and with relatively higher expression of the genes of interested. This improvement allows the manufactory can produce CAR-T cells in a most cost-effective way. Meanwhile, through the collaborating efforts, we are currently developing new platforms for generating save tools for CAR-T development by using CRISPR technology and the self-inactivated retro-viral vector. This collaboration will focus on the improvement in the Safety and efficiency of the procedures. Combining our several improvements, the result shows our method can be applied into current CAR-T production procedure and is with a significant impact to the operational timing and cost. In addition, our results are also suggested that the on-current procedure may be still with a lot of potential to be improved.

1070 OmniCAR - A Universal CAR T Cell Therapy to Target Multiple Antigens in Blood and Solid Tumours

Kevin Sek[1], Jasmine Li[1], Jun-Ming Tong[1], Rebecca Lim[2], Philip Darcy[1]
[1]Peter MacCallcum Cancer Centre, Melbourne, Australia,[2]Prescient Therapeutics, Melbourne, Australia

Background: Chimeric antigen receptor (CAR) T cell therapy has shown remarkable efficacy in treating blood cancers. However, conventional CAR T cell therapy has thus far shown limited efficacy in solid tumours, due to immunosuppression in the tumour microenvironment (TME), inefficient T cell trafficking, antigen heterogeneity etc. Relapse is common due to tumour escape. **Rationale and Aim:** Therefore, there is an unmet need for a new class of universal immune receptor (UIR) expressing CAR T cells which have the flexibility to target more than one tumor antigen and can be controlled with predictable dose-response kinetics. We demonstrate durable OmniCAR expression and 'arming' with targeting ligands against multiple antigens, with highly specific and inducible, potent activation and anti-tumor function against multiple blood and solid tumours. **Methods:** The OmniCAR UIR is comprised of two components, (i) a cell surface receptor expressed on T cells that consists of the SpyCatcher component and CD3ζ and 4-1BB intracellular signalling domains

and (ii) targeting ligands conjugated to an adaptor peptide sequence (SpyTag). When combined, the targeting ligand and OmniCAR form a covalent bond thereby arming the T cells. **Results:** In vitro co-culture with tumor cells demonstrated titratable dose-responses (0-1000nM binders) and potent anti-tumor cytokine production (IFN, TNF, IL-2) and killing against multiple solid and blood cancer cell lines. Furthermore, we demonstrated in mixed tumor cocultures, strict OmniCAR T cell antigen specificity, with anti-tumor killing elicited only against tumor cells expressing the corresponding target antigen. Sequentially adding a second targeting ligand can redirect OmniCAR T cells to target the tumor cells that initially escaped CAR T killing. In a murine model of HER2+ breast cancer, human OmniCAR T cells proliferated and engrafted without initial 'arming'. Potent therapeutic efficacy was only observed when the anti-HER2 targeting ligand was administered, leading to regression of large tumors. **Conclusion:** UIR are a rapidly emerging arm of adoptive immunotherapy, and here we have demonstrated the potential of the OmniCAR platform to address these challenges through increased safety and reduced side effects (switching on/off CAR responses in vitro and in vivo) and targeting multiple tumour antigens simultaneously or sequentially to overcome escape mechanisms such as antigen loss or antigen heterogeneity.

1071 AAV-ARSA Mediated Gene Replacement for the Treatment of Metachromatic Leukodystrophy

Shyam Ramachandran[1], Jeffery Ardinger[1], Jie Bu[1], MiAngela Ramos[1], Erik Wischhof[1], Johanna Adams[1], Yuxia Luo[1], Shelley Nass[1], Lilu Guo[2], Mariana Goncalves[2], Dhiman Ghosh[2], Mahmud Hossain[2], Catherine O'Riordan[1], Martin Goulet[1], Christian Mueller[1]

[1]Genomic Medicine Unit, Sanofi, Waltham, MA,[2]Precision Medicine and Computational Biology, Sanofi, Waltham, MA

Metachromatic leukodystrophy (MLD) is an autosomal recessive neurodegenerative disorder caused by mutations in the arylsulfatase A (*ARSA*) gene, resulting in lower sulfatase activity and the toxic accumulation of sulfatide in the central and peripheral nervous system. In MLD patients, this leads to progressive demyelination, cerebral atrophy, peripheral neuropathy, and shortened life expectancy. Therapeutic benefit of ARSA replacement has been demonstrated in a clinical setting and the sustained expression of ARSA by gene therapy is a promising strategy with potential to restore myelinogenesis, prevent additional atrophy and provide long lasting therapeutic benefit from a one-time treatment. We present an AAV-mediated gene replacement strategy to treat MLD and report therapeutic benefit in a MLD mouse model, and meaningful ARSA expression and biodistribution in non-human primates (NHPs). We report the nomination of a novel capsid AAV.GMU1, demonstrating better biodistribution and higher transgene expression in the CNS of NHPs, compared to a gold-standard CNS-tropic capsid. We demonstrate that AAV.GMU1-h*ARSA* mediated gene replacement in MLD mice (*Arsa*$^{-/-}$) resulted in the reversal of MLD-associated pathology. AAV.GMU1-h*ARSA* treated mice show increased sulfatase activity in the brain and spinal cord and a concomitant reduction in sulfatide levels (LC-MS) in the brain, spinal cord, CSF, and plasma. Treated MLD mice exhibit prominent and persistent h*ARSA* expression (measured up to 13 months post-dosing), secretion, and cross-correction. Furthermore, *Arsa*$^{-/-}$ mice treated with AAV.GMU1-h*ARSA* showed near complete absence of MLD-associated histopathology and absence of MLD-associated phenotypes. Further, a dose-range finding pharmacology and safety study was carried out in juvenile cynomolgus monkeys, that received four increasing doses of AAV.GMU1-h*ARSA*. We report widespread and dose-dependent increase in AAV.GMU1-h*ARSA* vector biodistribution in NHP brain, with clinically meaningful h*ARSA* expression in >90% of the brain. NHPs showed uniform h*ARSA* expression in the spinal cord and DRGs along the spinal rostral-caudal axis, and presented no clinical signs (functional or behavioral) for the duration of the study. In summary, we propose AAV.GMU1-h*ARSA* mediated gene replacement as a clinically viable approach to achieve broad and therapeutic levels of ARSA in the CNS and PNS.

1072 An Antibody-Based AAV Retargeting Platform for Efficient and Specific *In Vivo* Gene Delivery to the CNS

John Dugan, Kyle Plasterer, Pascaline Aime-Wilson, Nicole L. Keating, Caryn Galligan, Tazeen Ishmam, Rachel Sattler, Min Gao, Matthew P. Anderson, Lynn E. Macdonald, Christos A. Kyratsous, Leah Sabin

Regeneron Pharmaceuticals, Tarrytown, NY

Adeno-associated virus (AAV) is a leading viral vector used in gene therapy to treat human diseases. Although AAV has many advantages as a gene therapy vector, some of the limitations to its use for disorders of the central nervous system (CNS) are the inability of most wild-type AAV serotypes (AAV9, AAVrh10) to efficiently cross the blood-brain-barrier (BBB), as well as their tendency to preferentially transduce the liver. Although capsid library-based selection approaches are a powerful method to identify novel capsids with desired properties, the translatability of such capsids between species, particularly for human treatment, remains a challenge. Thus, we sought to develop a species-agnostic, modular AAV retargeting platform that utilizes rational capsid engineering and monoclonal antibodies to redirect viral particles to cross the BBB, while minimizing peripheral tissue transduction. Transferrin Receptor 1 (TfR) is a conserved receptor expressed on the apical surface of brain endothelial cells that is known to facilitate transcytosis of cargo across the BBB. We utilized a protein tagging system to covalently couple TfR antibodies or antibody fragments to surface-exposed variable loops on the viral capsid. We observed that multiple AAV serotypes can be efficiently retargeted to the CNS with anti-TfR antibodies following systemic administration, achieving comparable CNS transduction to wild-type AAV9 at considerably lower doses. We also found that multiple antibody formats, including bivalent antibodies, fragment antigen binding regions (fabs) and single-chain fragment variables (scFvs), can facilitate transcytosis of AAVs across the BBB. The natural tropism of the conjugated virus can be further modified by the introduction of specific mutations into the capsid sequence of the TfR-targeted vectors, which substantially reduce transduction of the liver and other non-CNS tissues without impairing the efficiency of CNS gene transfer. Finally, to select the most efficient, translationally relevant antibody candidates for BBB-crossing in humans, we screened 32 anti-human TfR fabs, using IHC and qRT-PCR to quantify their ability to mediate BBB-crossing and transduction

of the CNS following systemic delivery in mice expressing human TfR. Using this approach, we identified multiple fabs with a range of binding properties that facilitated potent AAV delivery to the brain. Our antibody retargeting platform provides a novel method to enhance delivery of AAV therapies to the CNS by targeting a conserved receptor, while simultaneously reducing off-target tissue transduction to mitigate safety risks. We aim to apply this technology to the development of therapies for diseases of the CNS.

1073 Production of AAV Vectors Using Synthetic, Enzymatically Produced Linear DNA

Céline Winckler, Ángel Picher, Heikki Lanckriet, Amy Walker

4BaseBio, Cambridge, United Kingdom

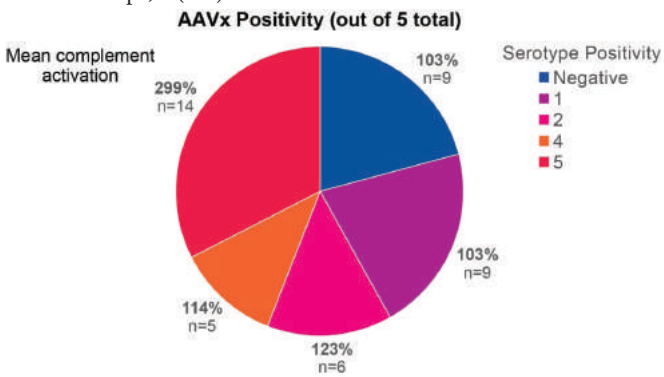
Adeno-associated virus (AAV) remains a popular vector for gene therapy. However, AAV manufacture faces several challenges to keep pace with the demand for large scale, high quality batches. The gold standard plasmid triple-transfection presents several issues including availability and cost of GMP grade plasmid, sequence fidelity of the Inverted Terminal Repeats (ITR), and safety concerns over non-specific encapsidations. 4basebio has developed a proprietary, scalable synthesis process for the production of linear closed DNA constructs via its Trueprime™ amplification technology. The hpDNA™ produced is devoid of any bacterial backbone and circumvents cumbersome fermentation processes required for plasmid DNA. The process is size and sequence independent, allowing for large scale production of linear DNA with high yield and purity in less than a week. Unlike plasmid DNA, 4basebio DNA eliminates contamination from endotoxins or host proteins, and excludes bacterial sequences such as antibiotic resistance genes. Here, we compared the production of AAV vectors using hpDNA™ encoding for the typical Adenovirus helper functions, *rep* and *cap* genes, and an expression cassette consisting of AAV2 ITRs and a GFP reporter gene driven by an ubiquitous promoter. Conventional plasmid triple-transfection was used as a control. We achieved equivalency in viral genome titres, Full:Empty ratios and infectivity between the two production methods. We have demonstrated that functional AAV vectors can be produced using hpDNA™, which could greatly accelerate therapeutic development of gene therapy programmes. The technology could overcome the difficulties associated with complex ITR structures required for AAV production, which are inherently difficult to synthesise via bacterial propagation systems. Moreover, the lack of plasmid backbone sequences such as antibiotic resistance genes enhances the safety profile of the AAV product.

1074 Characterization of Pre-Existing Immunity to AAV5

Kelly Lau

BioMarin Pharmaceutical Inc., Novato, CA

Seroprevalence studies indicate many prospective gene therapy (GT) patients have been previously exposed to adeno-associated viruses (AAV) and harbor pre-existing AAV antibodies, which may impact the administration and efficacy of GT. The objective of this study was to further characterize pre-existing antibody responses to AAV serotype 5 (AAV5) in severe hemophilia A patients (n=540) who are GT naïve. We evaluated AAV5 neutralizing factors (transduction inhibition, TI) using a cell-based assay, AAV5 total binding antibodies (TAb) using a bridging immunoassay, AAV serotype specificity using a bridging immunoassay, AAV5 complement activation, and AAV5 antibody isotypes. Most subjects with pre-existing immunity to AAV5 were positive for both TAb and TI, with a small subset showing discordant results. Pre-existing AAV5 TAb titers were much lower than AAV5 post-treatment titers. We previously[1] assessed the seroprevalence of pre-existing immunity to AAV5 and four additional AAV serotypes (AAV2, AAV6, AAV8, AAVrh10). Using those data, we assigned subjects to AAVx positivity groups (Negative, 1, 2, 3, 4, 5) based on the number of serotypes for which they were positive. There was no association between higher AAV5 TAb titers and the presence of antibodies reactive with other serotypes, suggesting that AAV5-specific TAb titers were not a result of broad previous AAV exposures (and subsequent cross-reactivity). In a subset of subjects (n=43) with and without pre-existing AAV5 TAb positivity, AAV5-induced complement activation was assessed in vitro by measuring complement split products (C3a, C4a, C5a and Bb). In some samples harboring AAV5 TAb, a >200% increase in activated complement split products was observed; however, this was not strictly correlated with the magnitude of AAV5 TAb titers. Complement activation was not observed in TAb-negative subjects, and not all TAb-positive subjects exhibited complement activation. An analysis of data based on AAVx positivity showed that mean complement activation to AAV5>200% in vitro was measured only in subjects that were positive for all five serotypes (AAV5/2/6/8/rh10). Activation of complement may enhance complement receptor-mediated clearance, alter the biodistribution away from the target tissue, and therefore reduce transduction. Finally, in another subset of subjects (n=78) with pre-existing AAV5 TAb positivity, we characterized the isotype and subtype of the anti-AAV5 response (IgM, IgG1, IgG2, IgG3, IgG4, IgA). Responses were predominantly the IgG isotype. Higher AAV5 TAb titers (>100) and TI titers (>60) were typically associated with detection of IgG1, but higher AAV5 TAb titers that were TI negative or low TI titer (<60) did not reveal a similar trend. Consequently, highly neutralizing antibody responses were associated with detection of AAV5-specific IgG1. Our in-depth characterization of pre-existing immunity to AAV5 can help elucidate the most important immunological determinants that limit AAV vectored transduction of target tissues. Understanding these determinants of pre-existing immunity could enable more patients to gain access to GT. 1. Klamroth R, Hayes G, Andreeva T, Gregg K, et al. Global Seroprevalence of Pre-existing Immunity Against AAV5 and Other AAV Serotypes in People with Hemophilia A. Hum Gene Ther. 2022 Apr;33(7-8):432-441.



1075 Gene Editing Repair in *USH2A* Knock-Out hiPSC-Derived Retinal Organoids

Rossella Valenzano[1], Andrew McDonald[1], Carmen Gallego[1], Manuel A. F. V. Gonçalves[2], Jan Wijnholds[1]
[1]Ophthalmology, Leiden University Medical Center, Leiden, Netherlands,[2]Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands

Background: Mutations in the human *USH2A* gene account for most cases of Usher Syndrome type II, a heterogeneous autosomal recessive disorder characterised by progressive retinitis pigmentosa and sensorineural hearing deficiencies. *USH2A* is one of the largest retinal disease-associated genes, with an open reading frame of 15.6 kb whose defects span missense, nonsense, indels, splice site and frame-shift mutations throughout its 72 exons. Mutational hotspots are located in exon 13, where a single nucleotide deletion (c.2299delG) represents the most common pathogenic variant. **Results:** Here, we developed *USH2A* knock-out (KO) human induced pluripotent stem cells (hiPSCs)-derived retinal organoids as a human model of *USH2A* retinal disease. The organoids will be used to investigate different viral gene editing approaches. First, we generated homozygote KO mutations in *USH2A* exon 13 by CRISPR-Cas9 system. We designed a single-stranded oligodeoxynucleotide donor containing a premature stop codon followed by an additional nucleotide to disrupt the *USH2A* open reading frame, which is expected to result into a non-functional Usherin protein. Subclones of these *USH2A* KO hiPSCs have been validated by sequencing, and are being checked for maintenance of pluripotency, differentiation capacity, karyotypic stability and copy number variation analysis, as well as absence of off-target events. The *USH2A* KO hiPSC clones are being differentiated into retinal organoids along with isogenic controls. The potential loss of Usherin protein and *USH2A* transcripts in the *USH2A* KO retinal organoids will be studied. In addition to disrupting *USH2A* exon 13, we are developing retinal organoids with nonsense mutations in exons 60 to 67 of *USH2A*. Previously, we tested transduction of retinal organoids by adeno-associated viral (AAV) vectors which can carry up to 4.5 kb of transgenic DNA. Here we will show transduction of retinal organoids by high-capacity adenoviral vectors (HC-AdV) that can incorporate up to 36 kb of transgene. In addition, we will present our AAV and HC-AdV vectors for Homology-Independent Targeted Integration (HITI) gene editing. **Discussion:** We successfully generated *USH2A* KO retinal organoids and showed efficient transduction of photoreceptors in cultured wild-type retinal organoids by HC-AdV. In future studies, we will fully characterise the *USH2A* organoids and compare the expected ciliary retinal phenotype at different timepoints. We plan to transduce the *USH2A* mutant organoids with AAV HITI *USH2A* editing vectors. However, the entire *USH2A* cDNA sequence is more than three times bigger than the AAV maximum transgene capacity of 4.5 kb. The largest *USH2A* cDNA fragment able to fit in the viral vector extends from exons 2 to 17. Therefore, we designed and constructed a vector incorporating *USH2A* exons 2 through 17 (4 kb) together with the required regulatory elements. This vector system will target *USH2A* intron 17 permitting the testing of a superexon approach for rescuing full-length *USH2A* expression in patient-derived retinal organoids. Double-strand DNA break repair in post-mitotic photoreceptor cells relies on non-homologous end joining (NHEJ). In this work, the DNA knock-in into *USH2A* introns in the retinal organoids will be mediated by HITI. We will examine whether AAV-mediated HITI gene editing will restore the expression of Usherin in the *USH2A* retinal organoids. The retinal organoids with nonsense mutations in *USH2A* exons 60 to 67 will be used to test insertion of 4 kb of *USH2A* cDNA containing exons 60 to 72 plus regulatory sequences into *USH2A* intron 59. We explore in addition the use of HC-AdV vectors for insertion of 15 kb of *USH2A* exons 2 to 72 cDNA and regulatory sequences into intron 1.

1076 A Novel Oncolytic HSV Sensitizes Resistant Glioblastoma Therapy and Anti-Tumor Immunity

Bangxing Hong
Pathology, Augusta University, Augusta, GA

The host immune system has developed multiple mechanisms to defend against and clear virus infections, including PKR, cGAS-STING and TLR-MyD88 signaling. Compromised anti-viral mechanisms in tumor cells allow for infection, replication and lysis by oncolytic virus. However, these compromised antiviral mechanisms, together with immune cells and tumor microenvironment, limit the sensitivity of oncolytic virus in tumor cells. We have generated a novel oncolytic virus oHSV-shPKR which disables tumor intrinsic PKR signaling. oHSV-shPKR results in suppression of innate anti-viral immunity and improves virus spread and tumor cell destruction in both oncolytic viral-resistant and sensitive GBM cells. oHSV-shPKR increases the activation of antigen presentation cells through type I interferon signaling activation and produces an immune-stimulatory function to increase tumor-antigen specific CD8 T cell expansion, including cytotoxic T lymphocytes. Preclinical studies show that intra-tumoral injection of oHSV-shPKR significantly inhibits human GBM PDX tumor growth in immune-deficient NSG mice and murine orthotopic GBM tumor growth in immunocompetent mice. Mechanistic studies using single cell and mRNA sequencing suggest that PKR positively regulates TGF-ß immune suppressive signaling. To our knowledge this is the first report to identify dual and opposing roles of PKR wherein PKR activates anti-virus innate immunity while it inhibits anti-tumor adaptive immune responses. Thus, the novel oHSV-shPKR has the potential to be used in clinical applications for both oHSV-resistant and sensitive GBM treatment.

1077 Mitigating a TDP-43 Proteinopathy Using RNA-Targeting CRISPR Effector Proteins

Maria Alejandra Zeballos, Hayden Moore, Jackson E. Powell, Sijia Zhang, Tyler Smith, Thomas Gaj
University of Illinois, Urbana, IL

Amyotrophic lateral sclerosis (ALS) and frontotemporal dementia (FTD) are currently incurable neurodegenerative disorders. While each disease affects distinct neuronal regions, ALS and FTD share a highly frequent pathological feature: the aggregation and ubiquitination of the TAR DNA-binding protein 43 (TDP-43). Given its apparent central role in ALS and FTD, TDP-43 has emerged as an important and potentially broadly applicable therapeutic target for both disorders. However, TDP-43 performs countless crucial cellular functions, which thus likely preclude its targeting for sporadic forms of the disorders. As a result, numerous attempts have been undertaken to identify gene targets whose perturbation can modify

TDP-43 toxicity without affecting its expression. One such modifier is ataxin-2, a polyglutamine-containing RNA binding protein that, when modulated, is capable of modifying TDP-43 toxicity without affecting its expression. Thus, strategies for targeting ataxin-2 may hold potential for ALS-FTD. In addition to traditional gene silencing modalities, CRISPR technologies have emerged as broadly effective platforms for perturbing the expression of a target gene, including potentially ataxin-2. Among the CRISPR-based platforms that can be used for this goal are RNA-targeting CRISPR effector proteins, which rely on an engineered CRISPR RNA (crRNA) molecule to recognize a target RNA sequence that facilitates its degradation by the CRISPR effector protein. This ever-expanding toolbox of effector proteins includes the Cas13 family of enzymes, which, after binding to a target RNA sequence, indiscriminately *trans*-cleaves non-target RNAs, as well as Cas7-11, a protein that cleaves its target RNA in *cis* and as such is thought to pose minimal risk for collaterally *trans*-cleaving non-target transcripts. Given their high programmability and capacity to knockdown the expression of target genes in mammalian cells, we hypothesized that RNA-targeting CRISPR effectors could be programmed to target ataxin-2 and consequently, mitigate ALS and FTD-associated TDP-43 pathology. In the present study, we find that RNA-targeting CRISPR effectors can target ataxin-2 to ameliorate a TDP-43 proteinopathy. Specifically, we show that Cas13-mediated ataxin-2 reduction in cell culture models can reduce the size and number of TDP-43 protein inclusions, as well as TDP-43 localization to stress granules, the transient cellular structures that accumulate protein and RNA in response to stress. We further validate the efficiency of our approach by delivering an ataxin-2-targeting Cas13 system to a mouse model of a TDP-43 proteinopathy. Our approach rescued motor impairment, enhanced strength, and dramatically extended survival. Finally, we utilize the ataxin-2 sequence to benchmark the specificity of second-generation high-fidelity Cas13 proteins and Cas7-11, finding that these effectors demonstrate markedly improved capabilities. Our results thus demonstrate that RNA-targeting CRISPR technologies can be programmed to silence disease-modifying proteins and hold potential for TDP-43 proteinopathies.

1078 Preclinical Development of an *Ex Vivo* Gene Therapy for Mucopolysaccharidosis Type II

Valentina Poletti[1], Sabyasachi Das[2], Fatlum Rruga[1], Agnese Dimartino[1], Annita Montepeloso[2], Janki Patel[2], Francesca Ferro[2], Eleonora Cavalca[2], Letterio Politi[3], Alessandra Biffi[1,2]

[1]Department of Pediatric Hematology and Oncology Center, Woman's and Child Health, University of Padova, Padua, Italy,[2]Dana-Farber/Boston Children's Cancer and Blood Disorders Center, Harvard Medical School, Boston, MA,[3]Neuroradiology Dept. Humanitas University and Hospital, Rozzano, Italy

Mucopolysaccharidosis type II (MPS II, Hunter syndrome) is an X-linked inherited disorder of carbohydrate metabolism. It is caused by mutations in the *IDS* gene, encoding the lysosomal enzyme iduronate-2-sulfatase (IDS). IDS deficiency causes glycosaminoglycan (GAG) accumulation in the lysosomes, leading to a severe impairment of cell metabolism and finally to cell death. The central nervous system (CNS) is particularly sensitive to this metabolic defect. MPS II causes distinctive facial features, visceral abnormalities and progressive intellectual decline, and the currently available treatment is only symptomatic.We designed an original approach based on hematopoietic stem cell gene therapy (HSC-GT) genetically modified by lentiviral (LV) gene transfer to restore the IDS expression. The approach was tested in vivo in pre-symptomatic and symptomatic MPS II mice. Experimental mice were monitored for survival, behavior and pathology hallmarks long-term. HSC-GT rescued behavioral, skeletal, biochemical and pathological disease-associated deficits and significantly increased animal survival, with all GT-treated mice out-surviving the control mock-transplanted mice. HSC-GT resulted in restoration of IDS activity up to 50% of the normal level and reduction of GAG accumulation in the brain of the treated animals. Safety monitoring of the treated mice did not show any treatment-related adverse events. Based on these results in the animal model of the disease, we assessed the HSC-GT strategy in a toxicology and biodistribution study in humanized immunodeficient mice (NSG). The study employed human HSPCs transduced with large-scale produced Lentiviral vector (LVV) and two different manufacturing protocols intended for clinical use, which differ in the total duration of the LV transduction, cell concentration and cytokine cocktail. Human HSPCs transduced with these protocols showed a preserved functionality in repopulated immunodeficient mice, as compared to mock-transduced cells, with a sustained engraftment up to 16 weeks post-transplant and multilineage differentiation. LVV profiling and *in vitro* immortalization assay revealed the absence of genotoxicity. Interestingly, we observed a robust engraftment *in vivo* of highly-transduced cells with respect to the infused cell products, which is currently being investigated. Overall, the study will be instrumental to a rapid progression toward the clinical development of our HSC-GT strategy for MPS II treatment.

1079 Plenty of Lenti - A Multi-Angle Approach towards Method Optimization of Lentivirus Production

Luisa Vetter[1,2], Kathrin Teschner[1], Niklas Kraemer[1,2], Alyssa Vetter[1], Sandra Klausing[1]

[1]Research and Development, Sartorius Xell GmbH, Bielefeld, Germany,[2]Faculty of Technology, Bielefeld University, Bielefeld, Germany

Gene and cell therapy applications will dominate the biopharma market in the coming years, much like antibodies did in the 2000s. One popular retroviral vector that is already in use for *ex vivo* administration is the lentiviral vector (LV). LV is increasingly used for cell therapy applications as it can transduce a variety of cell types as well as dividing and non-dividing cells. The latter is a game changer for treatment options, as these vectors can also transduce hematopoietic and T-Cells, cell types that have proven difficult to transduce for other viral vectors. However, challenges remain. One that has yet to be overcome is the current demand of LV quantities and required quality for clinical use. Therefore, more efficient production processes for high quality LVs are essential. Here we show how the upstream section of VSV-G enveloped LV production processes in HEK293 cells can be tweaked to help overcome these limitations. In a comprehensive optimization procedure, we tested different transfection protocols and were able to demonstrate the positive effect of adding fresh medium during the LV production process. A stability study for LVs was performed at 37 °C, in which the fragility of the vector during the production process was

investigated. A decrease in infectious viruses below detection limit after 24 h was observed. Based on these results, we compared different harvesting strategies where one single harvest step at the cultivation end versus multiple harvest steps including daily media change were performed. Despite the vector fragility, obtained data demonstrated no advantage in transducing units or total virus quantities when using multiple harvest steps, wherefore a single harvest is more expedient. Shelf life of stored LVs is also an important parameter and was monitored at storage conditions of +4 °C, -20 °C, as well as -80 °C over a period of three month by infectivity assay. Whereas negligible differences in LV infectivity at -20 °C and -80 °C were observed, viral titer at 4 °C showed a 10-fold decrease over time. Another focus of this work aimed at the comparison of the infectivity assay, in an adherent as well as in a suspension-based system. For this purpose, different protocols were investigated in more detail, with the protocol using adherent cells yielding higher transducing units. This work shows the importance of optimizing every step for efficient LV production.

1080 The Role of DNA/RNA Hybrids on the Efficiency of Nuclease-Free Genome Editing and AAV Integration *In Vivo*

Francesco Puzzo[1], Madzia P. Crossley[2], Katja Pekrun[1], Aranyak Goswami[1], Feijie Zhang[1], Karlene Cimprich[2], Mark A. Kay[1]

[1]Genetics and Pediatrics, Stanford University, Stanford, CA,[2]Chemical and Systems Biology, Stanford University, Stanford, CA

AAV viruses have a natural ability to stimulate homologous recombination (AAV-HR). In addition, rAAV vectors also integrate into numerous locations throughout the genome. We previously demonstrated a promoterless rAAV vector containing host genomic homology arms (e.g.*Albumin*) flanking a therapeutic coding sequence (e.g. human coagulation factor IX) induced homologous recombination in mouse liver (Barzel et al., Nature 2015). This resulted in a chimeric mRNA capable of producing the endogenous albumin and protein of interest from the same transcript. While this approach has led to therapeutic levels of a handful of proteins, the percentage of edited cells remains low (0.2- 1.0%). In order to attempt to enhance the number of AAV-HR positive cells, a genetic screen identified that the inhibition of the Fanconi Anemia complementation group M (FANCM) significantly improve the AAV-HR. FANCM is one of the enzymes required to resolve DNA/RNA hybrids, also known as r-loops, that can occur when a RNA filament anneals to a single strand DNA. The formation of r-loops takes place during DNA transcription and replication, and if not tightly regulated could lead to severe DNA damage such as single and double strand breaks. R-loops can be physiologically resolved by specific helicases such as FANCM or enzymes belonging to the RNase H family which degrade the RNA strand. Here, we report that the genetic inhibition of FANCM and SRSF1, two central proteins involved in r-loop formation, results in a significant 3-fold improvement of AAV-HR in vitro. In addition, using the small molecule topotecan, we demonstrated a significant increase in r-loop production in a murine hepatoma cell line (HEPA1-6) and mouse liver. Topotecan treatment resulted in a up to 15-fold enhancement AAV-HR in vitro and ~3-fold improvement in vivo. We were able to show the mechanism of improved AAV-HR efficiency was indeed due to r-loop formation by blocking the enhancement by co-treatment with RNAseH1, an enzyme required for resolving r-loops. We next elected to map and quantify r-loops throughout the genome. To this end, we performed DNA/RNA immune precipitation sequencing (DRIP-seq) studies in vitro and in vivo. To our knowledge, this represents the first genomic r-loop map of an intact tissue. Notably, we were able to detect massive r-loops accumulation in a specific region of the *Albumin* locus (exons 12-14) where we had designed homology targeting arms (Barzel et al. Nature 2015). We are currently doing comparative genomic studies of r-loop formation in hepatoma cells and intact liver and designing AAV-HR vectors to establish if regions rich in r-loops are predictive hotspots for both nuclease-free and nuclease-dependent AAV-HR. In addition, we also have preliminary data to suggest that regions enriched for r-loop formation are hotspots for "random" AAV vector integration. These findings may shed light on mechanisms helping to improve the safety and efficacy of in vivo genome editing and may enhance our ability to predict regions most susceptible to insertional mutagenesis with canonical rAAV vectors.

1081 Development of a Mass Spectrometry-Based Assay for the Detection of Endogenous and Lentiviral Engineered Enhanced Hemoglobin in Sickle Cells and Mice

Xuejun Wang[1], Theresa A. Dlugi[2], Mary L. Faber[2], William M. McKillop[1], Juliana Alvarez Argote[3], Andrew C. Wilber[4], Jeffrey A. Medin[2]

[1]Pediatrics, Medical College of Wisconsin, Milwaukee, WI,[2]Medical College of Wisconsin, Milwaukee, WI,[3]Medical College of Wisconsin, Pewaukee, WI,[4]Southern Illinois University School of Medicine, Springfield, IL

Sickle cell disease (SCD) results from a sequence defect in the adult hemoglobin (HbA) β-globin chain. SCD is traditionally diagnosed by cellulose-acetate hemoglobin (Hb) protein electrophoresis or high-performance liquid chromatography (HPLC). While clinically useful, these methods have sensitivity limitations. In efforts towards implementing a gene therapy approach for SCD, we first developed a novel mass spectrometry (MS)-based method for the rapid, sensitive, and highly quantitative detection of endogenous and lentiviral-encoded therapeutic β-globin. We have engineered a novel lentiviral vector based on the Lenti/βAS3-FB construct. The βAS3-globin transgene expressed from this vector contains the mutations G16D, E22A and T87Q that increase affinity for healthy β-globin and inhibit axial and lateral contacts with sickle β-globin, thereby conferring anti-sickling properties. Utilizing synthetic signature peptides for wild-type human β-globin, sickle β-globin, and βAS3-globin, we developed sample preparation methods and a MS-based assay to simultaneously detect each of these globins in cultured cells and small quantities of mouse peripheral blood. Using these MS methods, we have successfully phenotyped homozygous HbA (AA), heterozygous HbA-HbS (AS), and homozygous HbS (SS) Townes mice. We detected lentiviral vector-encoded βAS3-globin in transduced erythroid cell cultures and in transduced human CD34+ cells after erythroid differentiation. We also detected therapeutic βAS3-globin in peripheral blood six weeks post-transplant of transduced Townes SS bone marrow cells into Townes SS mice. This βAS3-globin persisted over 24 weeks post-transplant. With several genome-editing and gene therapy approaches for severe

hemoglobin disorders currently in clinical trials, this MS detection method will be useful for patient assessment before treatment and during follow-up.

1082 Chimeric Antigen Receptor (CAR) Natural Killer (CAR-NK) Cells for Treatment of COVID Patients

Minh Ma

Pathology, Immunology and Laboratory Medicine, Rutgers New Jersey Medical School, Newark, NJ

New severe acute respiratory syndrome coronavirus 2 (SARS-CoV2) variants continue to emerge, the newest variant of concern (VOC) Omicron subvariant XBB.1.5, imposing significant threats to the currently approved vaccines and therapeutics. Immunocompromised individuals are reported to facilitate SARS-CoV2 immune escape mutations throughout the infection course, leading to further SARS-CoV2 evolution. During the first peak of the pandemic, we first proposed to use chimeric antigen receptor (CAR) natural killer (NK) cell-based immunotherapy targeting the spike protein expressed on SARS-CoV2 for the treatment of COVID-19.NK cells provide the first line of defense against viral infections and tumor cells by secreting interferon-gamma to initiate the immune response. NK cells mediate antibody-dependent cell-mediated cytotoxicity by binding to the fragment crystallizable region of a neutralizing antibody (NAb) or mRNA-vaccine-induced antibody to trigger NK cell responses against SARS-CoV2-infected targets. However, SARS-CoV2 directly evades NK cell surveillance by downregulating NKG2D ligands, by which NKG2D is one of the major activating receptors. Moreover, clinical data showed that circulating NK cells are significantly reduced, dysfunctional, and exhibit an exhausted phenotype in severe COVID-19 patients. Altogether, these data indicate the important role of NK cells in controlling COVID-19 disease.Recent studies in CAR-NK cells showed promising results in treating lymphoid tumors with reduced toxicity, including graft versus host disease and cytokine release syndrome compared to that of CAR-T cells in clinical trials. However, one of the major challenges of using CAR-NK cells includes the ability to expand adequate non-exhaustive NK cells. Our lab developed a method to easily generate long-lasting 'memory-like' CAR-NK cells from peripheral and cord blood cells. We, therefore, designed autocrine expressing interleukin 15 (IL-15) third-generation CAR-NK cells expressing S309 single-chain variable fragment (henceforth S309-IL15-CAR-NK cells), where S309 NAb is demonstrated to neutralize both SARS-CoVs by binding to a highly conserved receptor binding domain region with high affinity. By challenging human angiotensin converting enzyme 2 NOD Scid gamma mice with USA/WA1/2020 followed by S309-IL15-CAR-NK cell or PBS treatments, we show that S309-IL15-CAR-NK cells significantly reduce the viral loads of SARS-CoV2 in the lungs of the treated group. We demonstrate efficient binding of S309-IL15-CAR-NK cells to SARS-CoV2 wildtype pseudotyped virus and its VOCs, including the B.1.617.2 (Delta), B.1.621 (Mu), and B.1.1.529 (Omicron). We also show that S309-IL15-CAR-NK cells effectively kill target cells expressing spike mutations derived from SARS-CoV2 variants *in vitro*. Our data collectively suggest the potential use of S309-CAR-NK cells for treating COVID-19 patients, especially those unresponsive to currently available therapeutics due to the emerging VOCs.

1083 Off-the-Shelf Third-Party HSC-Engineered iNKT Cells for Ameliorating GvHD While Preserving GvL Effect in the Treatment of Blood Cancers

Yanruide Li

University of California, Los Angeles, Los Angeles, CA

Allo-HSCT is a curative therapy for hematologic malignancies owing to GvL effect mediated by alloreactive T cells; however, the same T cells also mediate GvHD, a severe side effect limiting the widespread application of allo-HSCT in clinics. Invariant natural killer T (iNKT) cells can ameliorate GvHD while preserving GvL effect, but the clinical application of these cells is restricted by their scarcity. Here, we report the successful generation of third-party HSC-engineered human iNKT (3rdHSC-iNKT) cells using a method combining HSC gene engineering and in vitro HSC differentiation. The 3rdHSC-iNKT cells closely resembled the CD4 CD8 /+ subsets of endogenous human iNKT cells in phenotype and functionality. These cells displayed potent anti-GvHD functions by eliminating antigen- presenting myeloid cells in vitro and in xenograft models without negatively impacting tumor eradication by allogeneic T cells in preclinical models of lymphoma and leukemia, supporting 3rdHSC-iNKT cells as a promising off-the-shelf cell therapy candidate for GvHD prophylaxis.

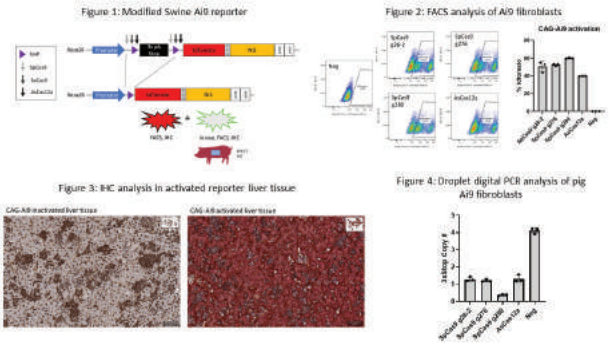
1084 CRISPR-Activated Biomedical Reporter Pigs for *In Vivo* Genome Editing Pre-Clinical Studies

Jarryd M. Campbell, Rebecca A. Milliken, Derek M. Korpela, Dennis A. Webster, Hinsoukpo V. Dagan, Adrienne Watson, Daniel F. Carlson

Recombinetics, Inc., Eagan, MN

Translating promising gene editing technologies such as CRISPR-Cas and base editor from basic research tools to therapeutics that cure genetic diseases require relevant preclinical testing to ensure the safety and efficacy. Preclinical studies in large animal models will provide critical data on dosing and safety of both the editor and the delivery vehicle prior to human use. Genetically engineered swine are beneficial as a preclinical model due to their similar size, anatomy, and physiology to humans as well as their <4 months gestation time and high fecundity (>6 per litter). Technology to produce gene edited swine has rapidly advanced, and custom-engineered swine that harbor the targeted therapeutic site from humans in their genome can now be made and delivered in less than 7 months. These animals are particularly useful for late-stage IND-enabling studies like dose-escalation, pharmacokinetics and pharmacodynamics analyses to streamline preclinical evaluation for gene editing-based therapies. In addition, these engineered animals can elucidate which organs, tissues, and cells will be targeted by the delivery vehicle in a large animal and allow for toxicity studies to be performed. One way of measuring the specificity of *in vivo* gene editing in specific organs, tissues, or cells is by using reporter lines, like those pioneered by the rodent community, including the Ai9 reporter. We have developed a biomedical research pig line with a modified Ai9 reporter at the *ROSA26* safe-harbor locus in pigs as part of the NIH Somatic Cell Genome Editing consortium. The modified Ai9 line includes a human Ubiquitin C or CAG promoter driving a tdTomato fluorescent reporter that is activated after DSB-

induced removal of a series of transcriptional stop signals (Figure 1). After activation, analysis can be performed in organs, tissues, and cells using immunohistochemistry, single cells using fluorescence activated cell sorting, molecular analysis, or direct sequencing (Figure 2-4). In addition to the fluorescent protein, the reporter will express a sodium iodide symporter (NIS) that will allow reporter activation to be detected non-invasively by PET or SPECT imaging for longitudinal studies. This model is available with a ~4 month lead time, and pre-clinical experiments can be performed at Recombinetics or through a contract research organization.



1085 *Ex Vivo* and *In Silico* Modelling of Human Innate and Adaptive Immune Responses to AAV Vectors

Manju Benakanakere[1], Deepa Jamwal[1], Kevin Yinho Kim[1], Maria Ruiz[1], Rebecca Xicluna[2], Hélène Haegel[3], Manon Wigbers[4], Rachel Rose[5], Inderpal Singh[6], Federico Mingozzi[1], Klaudia Kuranda[1]

[1]Spark Therapeutics, Philadelphia, PA,[2]F.Hoffmann-La Roche Ltd, Basel, Switzerland,[3]F. Hoffmann-La Roche Ltd, Basel, Switzerland,[4]Certara, Amstelveen, Netherlands,[5]Certara UK Limited, Sheffield, United Kingdom,[6]Spark Therapeutics, Chester Springs, PA

Despite clinical successes achieved with recombinant Adeno Associated Virus (AAV) therapeutics, host immune responses against the vector have been observed in numerous clinical studies. Understanding of these responses is limited by the high variability among individual subjects, insufficient or low sample size in rare disease gene therapy trials, the limited access to relevant clinical samples, and the lack of animal models that would be predictive of the cytotoxic immune response observed in humans. Given this gap in current knowledge, we have exploited human *ex vivo* systems previously validated for predicting immunogenicity of biological drugs, to identify assays reliably predicting AAV vector immunogenicity. Primarily, innate immune responses to AAV were mapped by measuring vector-induced pro-inflammatory cytokine release from the whole blood (WB) or the PBMC fraction isolated from healthy donors. Both methods showed that the increase in interleukin-6 had the highest magnitude across all tested cytokines and was the most frequent response among all tested donors (n=40), with the whole blood assay being more sensitive compared to the PBMC assay. Next, we showed that WB assay can be used to demonstrate differences in the immunogenicity of different AAV serotypes and manufacturing methods, or distinct innate activation patterns of DNA cargos packaged into identical capsid serotypes. Further, we used *in silico* analysis (EpiMatrix software) to confirm the relatively low immunogenicity of the AAV capsid protein compared to other viral epitopes or immunogenic antibodies. The presentation of AAV epitopes by human antigen presenting cells was further verified using the MHC-associated peptide proteomics (MAPPs) assay. The AAV epitope presentation was functionally verified by the DC:T cell proliferation assay performed using PBMC samples obtained from new set of healthy donors (n=40). We showed efficient proliferation of $CD4^+$ T cells, with only a minority of donors triggering $CD8^+$ T cell proliferation. In addition, a Fluorospot assay was used to further characterize AAV-specific $CD4^+$ T cells isolated from a subset of donors (n=20), which showed production of IFNγ and TNFα cytokines. Finally, using the above immune assay data, we adapted the Immunogenicity Simulator, a computational platform, to model a virtual AAV clinical trial (ranging from 40 to 500 virtual subjects). Identical to what was observed in real-life AAV clinical trials, modeling predicted the AAV dose- and time- dependent increase in anti-AAV antibodies and a correlation between the loss of AAV-transduced hepatocytes and the expansion of a pool of effector $CD8^+$ T cells. This work provides insights into the mechanisms driving human immune response to AAV vectors and lays the foundation for future correlations of immunogenicity predictions with clinical outcomes in gene therapy trials.

1086 Nanoplasmid™ Vector Platform for Superior AAV and mRNA Vector Yield and Stability

James Williams, Jeremy Luke, Tyler Kozisek, Aaron Carnes

R&D, Aldevron, Fargo, ND

The Nanoplasmid™ vector backbone (<500 bp) is a replacement for previous generation bacterial backbones that improves safety and performance of gene and cell therapeutics. Nanoplasmid vectors do not include antibiotic resistance markers which improves safety compared to plasmids or minicircles that rely on antibiotic resistance for bacterial selection. Nanoplasmid vectors also contain a specialized bacterial R6K replication origin in place of the traditional pUC replication origin, making the Nanoplasmid vectors replication-incompatible with native organisms—this is an additional safety factor that reduces Horizonal Gene Transfer risk, since Nanoplasmids™ can only replicate within the specialized *E. coli* host strain used for manufacturing. Two of the leading biotechnology platforms, Adeno-associated virus (AAV) gene therapy vectors and mRNA vaccines, encode structured DNA elements essential for their function. AAV transfer plasmids contain highly structured palindromic Inverted Terminal Repeats (ITRs) flanking the 'payload' transcription unit. These ITR repeats, which contain the viral replication origin and viral packaging signals, are highly unstable and difficult to replicate in Escherichia coli, creating challenges for AAV transfer plasmid manufacture. mRNA vaccines are manufactured from polyA -repeat containing template plasmid vectors that contain an antigen gene downstream of a bacterial promoter, and upstream of a polyA repeat. To manufacture the mRNA vaccine, the template vector is produced in *E. coli*, then linearized by restriction digestion downstream of the polyA repeat. A mRNA encoding the antigen gene with a stabilizing polyA tail is then produced by *in vitro* runoff transcription. Similarly to ITR repeats, the long (80-120 bp is

typical) polyA repeats are often prone to deletions and the vectors are often low yielding in Escherichia coli. To stabilize the structured DNA repeats in AAV and mRNA vectors, the typical approach is to use recombination deficient hosts such as SURE or Stbl4. While these strains can be used to stabilize and produce AAV and mRNA vectors in small scale shake flask culture, the multiple mutations characterizing these strains lead to very poor biomass and vector yields in the large-scale fermentation required for production of vectors for clinical and commercial applications. The REVIVER host strain, an engineered cell line that improves stability and replication of structured DNA sequences while retaining high fermentation productivity, is a superior high yielding *E. coli* host for manufacture of AAV transfer plasmids and polyA repeat containing mRNA template plasmids. Fermentation yields and stability are often lower with AAV transfer plasmid and polyA repeat containing mRNA template plasmids than standard plasmids. This appears to be due to the plasmid backbone encoded pUC replication origin having difficulty replicating closely positioned structured DNA sequences. We have developed an alternative R6K replication origin-based vector backbone, the Nanoplasmid backbone, which has dramatically improved fermentation manufacturing yields with these structured DNA containing vectors. Nanoplasmid retrofits of existing AAV transfer vectors or mRNA vaccine vectors stabilize and improve DNA vector manufacture, while not changing the sequence or composition of the vector payload (AAV virus or mRNA transcription unit in these cases).

1087 A Six-Day Enhanced Clinical Scale Manufacturing of Transduced T-cells for Immunotherapies

Fazil Turabe, Reichs Daven, Timothy Low, Wei Hseun Yeap, Zhen Jie Chin, Felicia Chin, Paula Y. P. Lam

Cellvec Pte Ltd, Singapore, Singapore

Chimeric antigen receptor (CAR) -modified T-cell therapy against CD19 has emerged as a significant therapy against relapsed/refractory lymphomas. However, patients typically require a high dose of T-cell infusion (~2 × 106 to 2× 108 T-cells/kg) for treatment while the manufacturing time to generate consistent CAR T-products cells is a lengthy process ranging from 8-14 days. Furthermore, quiescent, and naïve T cells are recalcitrant to the fusion of lentiviral particles. It is therefore necessary to either activate naïve T cells prior to transduction or to employ a high multiplicity of infection (MOI) of the lentiviral vectors (LVs) to overcome the limitation of hard to transduced primary T cells. Vectofusin-1, a soluble short cationic peptide is used to improve transduction efficient of murine CAR T cells. However, it was shown to exhibit lesser CAR-T transduction efficiency in comparison to RetroNectin. We have recently identified another novel type of soluble additive that exhibit similar T-cell transduction efficiencies as mediated by RetroNectin, and the goal of the current study is to determine the efficiency of T-cells transduction and expansion using this agent in an in-house optimized cell manufacturing process. In the latter, T cells were activated using soluble CD3/CD28 antibodies in a previously selected serum free media, denoted SFM#3, and spinoculation was performed together with the new additive using a second generation humanized CD19-CAR (CV -hCD19). As a reference, similar number of human peripheral blood mononuclear cells (2.7 x 10^8) from the same healthy donor were processed using the standard T-cell transduction (TCT) protocol whereby the cells were activated with TransAct while spinoculation was performed in the presence of vectofusin-1. Using the CliniMACS Prodigy platform, the results showed that 59.1% of T cells were positively transduced by CV-hCD19 at a MOI of 5 with a low vector integrant copy number less than 2. In contrast, 44.1% of CD19-CAR T cells were obtained using the same MOI with the standard TCT protocol. At day 6 where CD19-CAR T cells were harvested, the total number of CD3+ cells had increased from 49.3% to 91% (or 89% as in TCT protocol). Interestingly, CD19-CAR T cell fold expansion in our process was demonstrated to be double that of standard TCT protocol with no notable increase in exhaustion markers as compared to the non-transduced T cells. Moreover, we observed an improved fraction of self-renewing multipotent memory T-cells (Tscm+Tcm= >8%) in the final product using our method. The final CD19-CAR T-cells products from both methods were subsequently subjected to a co-culture cell kill assay using NALM-6-Luc tumor cells stably expressing luciferase. An augmented elimination of CD19 tumor cells (>20%) was also observed from cells using SFM#3 consistent with the higher transduction efficiency when compared to standard TCT. In conclusion, we were able to generate CD19 CAR+ T-cells with better CAR expression and efficacy, in a short six-day manufacturing process with final product attributes analogous to clinical formulations. An accelerated improved expansion protocol for CAR T-cells manufacturing would reduce the cost of goods and improve patient access to CAR-T cell therapies for increasing patient benefit.

1088 A Novel Homogenous Bioluminescent Immunoassay to Quantitate AAV Capsid Titer and Manufacturing-Related Protein Impurities

Trish Hoang, Rod Flemming, Jeff Nelson, Kara B. Machleidt, Vanessa L. Ott, Marjeta Urh

Promega Corporation, Fitchburg, WI

Adeno-associated viruses (AAVs) have gained significant attention in the field of gene therapy due to their capacity to effectively deliver therapeutic genes into human cells. Recombinant AAVs (rAAV) are produced primarily in mammalian cell culture. Despite extensive viral purification processes, removal of protein impurities has been difficult. Current methods to assess AAV capsid titer and protein impurities present challenges including low sensitivity, high cost, and laborious workflow. We have developed a homogenous (no-wash) plate-based immunoassay technology that can accurately quantitate rAAV viral capsid titer and detect residual protein contaminants from rAAV manufacturing. The Lumit™ immunoassay platform is based on NanoLuc® Binary Technology (NanoBiT®), which is a structural complementation reporter composed of two subunits: Large BiT (LgBiT) and Small BiT (SmBiT). Antibodies against the analyte of interest are labeled with either LgBiT or SmBiT. Upon binding to the analyte, the antibodies bring the SmBiT and the LgBiT subunits into close proximity, resulting in the reconstitution of a functional luciferase. Consequently, luminescent signal production is directly proportional to the amount of analyte. To develop Lumit™ AAV immunoassays, antibodies against specific serotypes were selected and labeled with SmBiT or LgBiT. Standard curves of rAAV2, rAAV8 and rAAV9 generated with our Lumit™ immunoassays displayed outstanding sensitivity, with up to 3 orders of magnitude in dynamic range. Lumit™ immunoassays can tolerate a variety of sample matrices including cell

lysate, viral lysis buffer, and purification buffers. Furthermore, during AAV manufacturing, there are several common sources of protein impurities, including host cell proteins, benzonases, and human serum albumin. We have also developed Lumit™ immunoassays for each of these impurities, all of which showed significantly improved sensitivity at limit of detection compared to the respective ELISA assays. Overall, our data show that the Lumit™ immunoassay is a powerful alternative to conventional ELISAs for quantifying rAAV viral capsids and detecting protein impurities during rAAV manufacturing. Lumit™ immunoassays allow for rapid analyte quantitation with simple, sensitive, and reproducible workflows.

1089 Optimizing PSCA CAR T Cells with Bispecific T Cell Engagers to Target Two Distinct Subtypes of mCRPC

Lupita S. Lopez, John P. Murad, Maciej Kujawski, John Shively, Saul Priceman

City of Hope, Duarte, CA

Metastatic castration resistant prostate cancer (mCRPC) comprises of two distinct sub-types, prostate adenocarcinoma (PrAd) and neuroendocrine prostate cancer (NEPC). Treating advanced mCRPC remains a significant challenge effective treatment strategies are needed. Current targeted therapies often result in transient anti-tumor responses and often lead to antigen-negative tumor outgrowth. Chimeric antigen receptor (CAR) T cell therapies are being actively investigated to target mCRPC, including CARs targeting prostate stem cell antigen (PSCA), which is overexpressed in PrAd. However, it is anticipated that for durable antitumor responses, NEPC-targeting will be required. Carcinoembryonic antigen (CEA) is overexpressed in NEPC and may be effectively targeted with T cell engagers. Here, we outline the development of mouse PSCA-CAR (mCAR) T cell therapy in combination with a CEA bispecific to target mCRPC in a clinically relevant syngeneic tumor model. This model was developed to express human CEA and PSCA allowing us to evaluate safety of this dual targeting strategy. Initial *in vitro* studies interrogated the efficacy of PSCA mCAR T cells loaded with a murine dual bivalent CD3xCEA bispecific T cell engager (CEA dbBiTE). We found that although antigen-specific cell lysis was observed, the presence of dbBiTE on the surface of T cells was short lived. To address this, we optimized manufacturing and loading of mCARs. Current studies are underway to optimize the treatment strategy of PSCA mCAR T cells loaded with CEA dbBiTE *in vivo*. Future work will evaluate the *in vivo* safety and efficacy of PSCA mCAR T cells engineered to co-target CEA for the treatment of advanced heterogeneous mCRPC.

1090 Establishing a Platform Process to Manufacture the Highest Quality Precision Plasmids

John Bowen

The Center for Breakthrough Medicines, King of Prussia, PA

Since the first pharmaceutical application of plasmids (their introduction into bacteria to enable the production of therapeutic proteins) was achieved in the 1970s, plasmids have become critical starting materials for many advanced drug products. They are used to transfect mammalian cells to manufacture complex recombinant proteins, antibodies, and other biologic drug substances. With the increasing investment in advanced therapies such as viral vectors, cell-mediated, and nucleic acid-based modalities, plasmid manufacturing has become a major bottleneck to deliver these therapies. Plasmid transfection into mammalian cells is the predominant production method for viral vectors. Plasmids also serve as the template for mRNA manufacturing and have potential applications as vaccines and other therapeutics. Establishing a platform plasmid manufacturing process that is robust, scalable, and generates high quality pDNA that meet stringent regulatory requirements is necessary to support advanced therapy manufacturing. To develop such a manufacturing platform requires in-depth knowledge of the upstream, mid-stream, and downstream unit operations (specifically when different E. coli strains and a range of plasmids are used). A design-of-experiment (DoE) approach was taken to characterize processes and determine critical processparameters (CPPs) that impact critical quality attributes (CQAs) for E. coli fermentation and downstream plasmid purification. Subsequent data will highlight critical process parameters and their impact on both yield andquality. To develop a flexible platform, the upstream DoE approach explored different plasmid characteristics (size, complexity, and origin of replication) and multiple E. coli strains. Four different plasmid sequenceswere investigated. Three plasmids representing commonly used sequences for the production of recombinant AAV vectors, including pRepCap, pHelper, and pGOI (gene of interest) were chosen. The pGOI constructrepresents the complex secondary ITR sequence that can be difficult to properly amplify due to its complex repeating structure. The fourth plasmid was a green fluorescent protein (GFP) reporter plasmid with longterminal repeat (LTR) sequences for lentiviral (LV) vector production. This case study will highlight a flexible platform for plasmid DNA manufacturing

1091 CRISPR Based Site-Directed RNA Editing in Patient iPSC-Derived Neuronal Models of Genetically-Linked Intellectual Disabilities

Jasmine L. Carter, Julian Halmai, Jennifer Waldo, Paula Vij, Maribel Anguiano, Jan A. Nolta, Kyle D. Fink

UC Davis, Sacramento, CA

Pathogenic G-to-A mutations that manifest as neurological disorders have traditionally been challenging to edit in neuronal cells as current strategies require host-cell DNA repair pathways and incorporation of a template sequence. ADAR2 is a brain-enriched protein which post-transcriptionally modifies double-stranded RNA (dsRNA) by deaminating adenosine nucleotides to inosine, thereby enabling translational machinery to create a functional adenosine to guanosine edit within the transcript. The CRISPR associated protein 13 (dCas13b) is a catalytically inactive RNA binding protein which can achieve site-directed RNA editing when fused to the ADAR2 deaminase domain (ADAR2DD). A guide RNA (gRNA) sequence forms a dsRNA substrate for dCas13b-ADARDD2 binding at the complementary target while enabling RNA editing at a single base. In addition, designing the gRNA with a cytosine nucleotide opposing the target adenosine further specifies ADAR2DD activity within the target transcript. However, the CRISPR Cas13 system has yet to be employed for RNA editing of endogenous G-to-A mutations in neuronal cells. Our lab created induced pluripotent stem cell (iPSC) from fibroblasts of individuals with a pathogenic G-to-A mutation in exon 5 (E198K) of protein

phosphatase 2, regulatory subunit B', delta (*PPP2R5D)* which are causative for the neurodevelopmental disorder Jordan's Syndrome. Here, we have differentiated isogenic and variant iPSCs to neural stem cells (NSCs) to evaluate RNA editing efficiency and efficacy. Towards this goal, we have designed and screened exon 5 (E198K) gRNA to identify lead gRNA which have high on-target editing and low-to-moderate off-target editing in the *PPP2R5D* transcript. We demonstrate gRNA length and A-C mismatch position as important factors for on-target editing efficiency. We have further expanded our disease model by differentiating isogenic and E198K NSCs to neurons to understand the neurodevelopmental consequence of G-to-A mutations on *PPP2R5D* targets at the phosphoproteomic and transcriptomic levels. In addition, these studies have provided insight into potential pathways that are candidates for molecular rescues with our CRISPR RNA editing approach. Our future work is focused on employing the CRISPR RNA editor system in these patient-specific neuronal models. These studies support the potential for the CRISPR/dCas13b system to selectively edit mutant transcripts harboring G-to-A mutations in neuronal cells while providing an alternative editing technology for neurodevelopmental disorders.

1092 The VeCap® Platform: Structurally Engineered Tissue Specific AAV Capsids

Giulia De Sabbata, Carmen Gallego, Daan Boogers, Wouter Pos, Marina Sogorb, Svetlana Pasteuning, Roland van Dijk, Farangis Sharifi, Stella Fick, Merel Kessler, Andreia Duarte, Jolanda Snapper, Sander Van Deventer, Pavlina Konstantinova, Barbara Sanders

VectorY Therapeutics, Amsterdam, Netherlands

Recombinant Adeno Associated Virus (rAAV) vectors are the leading gene delivery tool for human gene therapy because of their advantageous safety profile and potential long-lived therapeutic effect. However, the broad tissue tropism and the high vector dose required to sufficiently transduce the target organ are still limiting factors for their clinical use. At VectorY, we have established a modular platform aimed at generating VeCaps®, Next Generation tissue specific rAAV capsids. We have designed a rational approach to engineer the rAAV capsid utilizing protein structural engineering to enable capsid binding to a specific cellular membrane protein (or receptor). Target membrane proteins are identified via defined selection criteria and novel peptides are designed to bind these proteins, followed by structural integration of the peptides to the viral surface. Via the structural engineered specific peptides, these novel VeCaps® convey specific tropism and improved transduction efficiency. VeCaps® are produced in a baculovirus/insect cell-based manufacturing process, resulting in high yields of rAAV vectors with a scalability advantage. The VeCaps® are screened and selected in a panel of human primary and iPSC-derived, 2D and 3D, *ex vivo* models relevant to Central Nervous System, and validated in large animals for biodistribution. Our platform provides the opportunity to explore capsid engineering in conjunction with functional data, to accelerate the rational design of AAV capsids that will advance VectorY's vectorized antibody programs. Through this approach, we, in a short time, identified multiple VeCap® variants that show up to 100-fold improved transduction, when compared to the commonly used HEK-produced AAV9. Work is ongoing to characterize the biodistribution of the lead candidates in Non-Human-Primates. In conclusion, the VeCap® platform provides a rapid capsid development platform with high success rate to generate potent and tissue-specific rAAVs compatible with industrial scale processes.

1093 Targeting FVIII Expression to Liver Endothelium

Ester Borroni, Chiara Borsotti, Roberta Annamaria Cirsmaru, Vakhtang Kalandadze, Rosella Famà, Simone Merlin, Antonia Follenzi

Dept of Health Sciences, University of Piemonte Orientale, Novara, Italy

Hepatocytes have long been considered the FVIII producer cells and thus key target cells for HA cell and gene therapy. However, recent studies have demonstrated that FVIII is largely synthesized and secreted by endothelial cells (ECs), and specifically by liver sinusoidal endothelial cells (LSECs). LSECs represent the main population of non-parenchymal cells in the liver and the major source of FVIII in the body, therefore they represent a suitable target for gene therapeutic approaches. Among the different functions that belong to LSECs, one is their high endocytic activity through clathrin-dependent endocytosis mediated by scavenger receptors and resulting in the clearance of waste from the bloodstream. Stabilin-2 (STAB2) is a scavenger receptor and is involved in the binding, uptake and degradation of multiple ligands such as hyaluronic acid and factor-FVIII complex. Our group previously demonstrated in a murine HA model that transduction of LSECs with a LV carrying the FVIII transgene under the control of an endothelial promoter is able to correct the bleeding phenotype for long term with no inhibitor formation. Since STAB2 is normally expressed by LSECs, we investigated whether the STAB2 promoter could be used to direct specific *in vivo* expression in LSECs upon LVs transgene delivery, thus resulting in a stable expression of the therapeutic protein due to the presence of natural regulating elements within cells and to the tolerance induction against the delivered transgene. To these aims, we *in vivo* delivered in mice by LV injections two transgenes driven by the STAB2 promoter: GFP, as a reporter gene for investigating the cell-specific expression and the tolerance induction; FVIII for testing the therapeutic correction of the hemophilic phenotype. To investigate the role of STAB2 promoter in modulating *in vivo* the immune response in the liver of LV-injected mice, we employed the Jedi mice which present a high percentage of GFP-specific TCR CD8 T cells. LV.STAB2-GFP and LV.PGK-GFP have been injected in B10D2 mice, syngeneic with Jedi mice, and at day 10 CD8 T cells isolated from B10D2 (control) or from Jedi mice have been adoptively transferred into B10D2 mice. GFP expression was analyzed 14 days after LV delivery by IF of livers. GFP expression driven by STAB2 promoter was visible in all the conditions, with no differences between mice that received only the vector or CD8 T cell injection. In particular, despite the use of Jedi CD8 T cells, which specifically detect the transgene (the epitope of the GFP expressed by MHC II), GFP was clearly present in endothelial cells, recognized by their typical shape in contrast with F4/80 staining lining the macrophages. To study whether endothelial-specific FVIII production would support long-term transgene expression in a different immunocompetent mouse strain, we injected HA mice with both LV.STAB2-hFVIII. Again, no plasma anti-FVIII antibodies were found in both vectors used (leading FVIII), with detected activity of the transgene in plasma maintained between 10 and 14 % respectively over time. The activity was sustained until 52 weeks, the longest time tested,

confirming that correction was achieved in all injected mice. These final data reinforce our hypothesis that endothelial-specific expression driven by STAB2 promoter leads to stable FVIII expression and activity without the formation of neutralizing antibodies in immunoreactive HA mouse strains, confirming the power of this novel promoter.

1094 AAV Gene Therapy for TNNT1 Nemaline Myopathy

Hannah Villeneuve[1], Erin Hall[1], Jillian Gallagher[1], Toloo Taghian[1], Abigail McElroy[1], Hector Ribeiro Benatti[1], Stephanie Bertrand[2], Ana Rita Batista[1], Laura Poskitt[3], Kevin A. Strauss[3], Miguel Sena-Esteves[1], Heather L. Gray-Edwards[1]

[1]Horae Gene Therapy Center, University of Massachusetts Chan Medical School, Worcester, MA,[2]Tufts University Cummings School of Veterinary Medicine, North Grafton, MA,[3]Clinic for Special Children, Strasburg, PA

TNNT1 Nemaline Myopathy is a fatal congenital disease caused by mutations in the TNNT1 gene encoding for the slow skeletal troponin T1 subunit in the sarcomere. The troponin T1 subunit links the troponin complex to tropomyosin, forming the troponin-tropomyosin complex. Numerous recessive genetic mutations, as well as one dominant mutation, affecting the TNNT1 gene have been described. The first and most extensively described mutation is the c.505G>T homozygous nonsense founder mutation resulting in a premature stop codon in exon 11, affecting the Old Order Amish population of Pennsylvania, USA. The Amish mutation results in the loss of tropomyosin-binding site 2, and all recessive mutations described thus far affect the C-terminal region of the troponin T1 protein. The Amish mutation is characterized by progressive muscle weakness and pectus carinatum, resulting in hypoventilation and fatal respiratory insufficiency around 24 months of age. Like other nemaline myopathies, histology of muscle tissue of TNNT1 Nemaline Myopathy patients shows rod-like aggregates in the sarcoplasm. In our experience, a published TNNT1 knock-out mouse model displayed no overt phenotype and unexpectedly, western blot analysis detected TNNT1 protein in knock-out mice. Considering these challenges, we generated a new TNNT1 knock-out model with a deletion of exons 2 through 14 using CRISPR/Cas9. As of 8 weeks of age, no overt phenotype has been detected. To fully characterize this new model, treadmill endurance testing, rotarod, plethysmography (respiratory) testing, and western blot analysis are underway. Currently, the new TNNT1 KO mouse colony is fully expanded and new AAV gene therapy experiments are being initiated. We developed several vectors encoding human TNNT1 with expression driven by different muscle specific promoters for packaging in AAV8 and AAV-MYO2A. Additionally, we obtained embryos of a natural TNNT1 Nemaline Myopathy merino sheep model from Australia which we intend to use as a large animal model for future therapeutic development.

1095 circAde, a Vector System for Spliceosome Dependent circRNA Biogenesis and Prolonged More Effective Protein Expression

Eoghan Thomas O'Leary[1,2], Sara Vikberg[1,2], Emelie Foord[1,2], Erik D. Wiklund[1], Lone Ottesen[1], Victor Levitsky[1], Thomas B. Hansen[1]

[1]Targovax ASA, Lysaker, Norway,[2]Clintec, Karolinska Institutet, Stockholm, Sweden

Circular RNA (circRNA) constitutes a novel class of endogenously expressed RNA. In contrast to mRNA, circRNAs are resistant to exo-nucleolytic decay which results in high intra-cellular stability and persistence. Understanding of circRNA production, both *in vitro* and *in vivo*, has improved significantly in recent years, and it is now feasible to engineer circRNAs for highly efficient protein translation. As such, engineered circRNAs are emerging as a novel therapeutic concept that may overcome several challenges facing mRNA. Production of therapeutic circRNAs can be achieved by two distinct mechanisms, either 1) using group-I-intron derived ribozymatic circularization for *in vitro* production, or 2) using spliceosome-based backsplicing similar to endogenous circRNA biogenesis for *in vivo* production. In the latter setup, inserting flanking inverted repeat (IR) elements is known to stimulate backsplicing dramatically by positioning the splice sites involved in close spatial proximity. Here, we show that our proprietary circRNA expression system, circAde, allows high yield circRNA production through spliceosome-dependent biogenesis. Using a panel of proof-of-concept-reporters, we show that certain design-features greatly influence circRNA production and subsequent protein expression, in particular choice of IR and IRES (internal ribosome entry sequence) elements. Publicly available RNA sequencing datasets were interrogated to identify IR elements flanking the most abundant circRNAs across multiple cell types. Candidate IRs were tested in our circAde system, and those capable of stimulating the highest level circRNA production, were modified to further enhance circRNA yield. Devoid of a 5'cap, circRNAs rely on IRESs for effective translation. Surprisingly, in addition to facilitating circRNA translation, we observe that choice of IRES also impacted circRNA biogenesis and yield. By conducting two orthogonal IRES screens on 1000+ putative IRES elements, we have identified the most effective IRES sequences in melanoma and lung-cancer cell lines supporting effective circRNA production and high-yield protein expression. Furthermore, comparing protein output from circAde and mRNA-based vectors, we show that the circAde-system out-performs conventional mRNA-based approaches, both in terms of transgene yield and temporal sustainability of expression. In addition, the circAde-system is highly versatile when it comes selection of both transgene payload and vector backbone. In summary, our results demonstrate technical proof-of-concept for a new platform for development of novel, more effective strategies for the treatment of diseases requiring durable transgene expression.

1096 Precision-Targeted Epigenome Editing Enhances CAR T Functional Profiles and Anti-Tumor Activity

Lucas J. Thompson[1], Akiko Seki[2], Alexandra Croft[1], Nathaniel Chartrand[1], Tyler Klann[2], Jason Dean[1], Andrew Hill[1], Nicole DeNamur[1], Blythe D. Sather[1]

[1]Research, Tune Therapeutics, Seattle, WA,[2]Research, Tune Therapeutics, Durham, NC

Cell-based immunotherapy with gene-modified T cells with a synthetic Chimeric Antigen Receptor (CAR T) has become a successful clinical treatment paradigm for hematological malignancies, though effectiveness in solid tumors has been elusive. Clinical experience in the heme setting has helped to define some mechanisms of disease relapse with initial generation of CAR T cells, revealing important roles for cellular persistence and functional potency for mediating durable clinical responses. In the solid tumor setting, achieving clinical success has proven to be more difficult, with functional persistence of CAR T cells being hampered by sustained antigen exposure and suppressive features of the tumor microenvironment (TME) driving T cell functional exhaustion. Current preclinical data demonstrating enhanced CAR T cell activity - either by transgenic gene overexpression or gene knock-out(s) to modulate molecular pathways - suggest that engineering of T cells beyond CAR may have beneficial clinical effects that could overcome treatment hurdles in solid tumor settings. However, these approaches result in permanent or non-physiological molecular alterations of cells that may not be ideal for the inherent biology or plasticity of T cells. Additionally, it is likely that modulation of multiple molecular networks is necessary to overcome biological barriers needed to achieve clinical benefit against solid tumors, presenting a significant safety risk for engineering approaches that rely on breaking the DNA strand. Targeted repression or activation of individual genes has been shown using modified gene-editing molecules such as enzymatically-dead Cas9 (dCas) linked to protein domains that activate or inhibit gene transcription via recruitment molecular complexes, without physical disruption of the DNA sequence. Here we show for the first time transiently-delivered dCas epi editing constructs mediating activation or repression of key target genes for improving CAR T cell function. Electroporation of T cells with dCas-epi editor mRNA and gRNAs during CAR T cell production results in temporary expression of the targeted epi editor molecule, followed by a durable modulation of target genes, which is maintained through cryopreservation and functional assays, both in vitro and in vivo. CAR T cells treated with the epi editor and target-specific guide RNA demonstrated markedly improved attributes associated with functional persistence, including elevated expression of key effector cytokines (IL2, IFNg, TNF), enhanced proliferation, and sustained serial target cell killing. Using a subcutaneous xenograft model of Her2-expressing human non-small cell lung cancer cell line NCI-H1975, Her2-specific human CAR T cells treated with dCas-epi editor mRNA and gRNAs exhibited superior tumor control and survival of engrafted mice, with enhanced pharmacokinetics of the CAR T cells in the blood. We furthermore demonstrated that the transiently-delivered dCas-epi editor mRNA and gRNAs can be multiplexed to achieve compounded impacts on functional qualities of the CAR T cells. These results demonstrate a novel approach to safely and effectively epigenetically modulate T cells in a precisely targeted manner to achieve improved outcomes in clinically relevant models of CAR T cell function.

1097 An Artificial Intelligence Approach to Extract Domain-Specific Insights from over 5,000 ASGCT Conference Abstracts

Eugenia Lyashenko[1], Bhupinder Dhillon[2], Sourav R. Choudhury[1]

[1]AAV Technologies Laboratory, Genomic Medicine Unit, Sanofi, Waltham, MA,[2]AI and Deep Analytics, R&D Digital and Data Sciences, Sanofi, Cambridge, MA

Natural Language Processing (NLP) is a subfield of Artificial Intelligence (AI) that has been used to process large corpus of natural language data to enable human interpretation. Here we build a gene therapy-specific NLP platform to parse through over 5,000 abstracts from the past 5 years of ASGCT Annual Meetings and extract domain specific topics. Briefly, the abstracts were parsed and represented as numerical vectors via embeddings in a biomedical domain specific language model. The abstracts were then clustered by similarity, and top occurring words per cluster were derived, essentially representing topics captured in the similar abstracts. This Semantic Topic Modeling approach leverages context captured in the dense embeddings. Expert curation of derived topics helped refine data-derived topics relevant to gene therapy domain. We were thus able to represent the whole corpus of abstracts in distinct specific topics based on unbiased text analysis, rather than category of abstract submission. Our platform can be used for exploration of large gene-therapy specific collections of text data, such as articles from PubMed or conference proceedings. The platform can be extended to derive a gene-therapy specific knowledge graph to facilitate discovery of emerging relationships between concepts, or to track trends in the field by quantifying changes in representation of various topics over time. We expect that this application would be of interest to researchers trying to isolate topic-specific information from domain-specific large publications datasets.

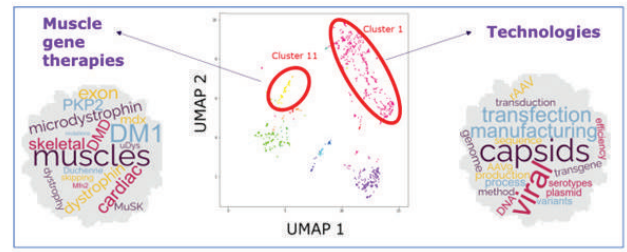


Figure 1: Exploring 2022 ASGCT Annual Meeting themes: abstracts are clustered and most frequently occurring words elucidate the topic of the cluster. For example, inspecting Cluster 1, we see that capsid engineering and manufacturing are the leading themes of the Technologies cluster.

1098 AAV-NRIP Gene Therapy Rescues Motor Functions in Amyotrophic Lateral Sclerosis Model Mice

Show Li Chen

Microbiology, National Taiwan University, Taipei, Taiwan

Nuclear receptor interaction protein (NRIP) is calcium/calmodulin binding protein involved in muscle functions. Both global NRIP

knockout mice (gKO) and muscle-restricted NRIP knockout (NRIP cKO) show muscular weakness. The interaction between motor neuron (MN) and muscles is mutual regulation for muscle contraction. Intriguingly, loss of muscle NRIP can retrogradely cause motor neuron degeneration in mouse model; indicating muscle NRIP can retrogradely control motor neuron growth. Additionally, NRIP can directly interact with acetylcholine receptor (AChR) as a component of neuron muscular junction (NMJ) formation. Hence, NRIP is a novel AChR binding protein to stabilize NMJ. The abnormal NMJ is a major cause of motor neuron degeneration (MND). The disease of amyotrophic lateral sclerosis (ALS; is one of the MNDs) show progressive neurodegeneration and abnormalities at the NMJ. Until now, there is not yet a cure treatment in ALS. Due to NRIP functions for NMJ maintenance, the role of NRIP in $hSOD^{G93A}$ mice (ALS mouse model) would be interesting to explore; and it may be able to develop NRIP as a therapeutic agent for ALS. Our preliminary results showed that the protein expression of NRIP in spinal cord, gastrocnemius (GAS) and tibialis anterior (TA) muscles were downregulated in $hSOD^{G93A}$ mice compared with WT mice. AAV-NRIP gene therapy in $hSOD^{G93A}$ mice was performed to evaluate the efficacy of AAV-NRIP in $hSOD^{G93A}$ mice. The results revealed the forced NRIP expression by AAV in SOD^{G93A} mice partially rescued motor neuron number, increased NMJ formation, enhanced axon innervation along with increased compound membrane action potential (CMAP) and motor functions. In sum, AAV-NRIP can be a potential drug for ALS in the future.

1099 coAAV Vectors from the AAV-Ligand Conjugate (ALIGATER™) Platform Outperform AAV9 to Address Neurological Disorders via CSF Delivery

Alexianne Gougerot[1], Adrien Savy[1], Nitza Thomasson[2], Kamelia Kara-Ali[1], Lavaniya Kunalingam[1], Ludmila Juricek[1], Patrice Vidal[1], Gaelle M. Lefevre[1]

[1]COAVE THERAPEUTICS, Paris, France,[2]NTZ Consulting, Paris, France

Adeno-associated virus (AAV) is the vector of choice for *in vivo* gene therapy. One of its most exciting advantages lies in its versatility in terms of applications and routes of administration (RoA). Consequently, the AAV platform has evolved quickly over the past decade, moving from the historical natural capsids to hundreds of new synthetic variants, all with their own set of transduction properties. The technology however still faces many challenges and improving features such as vector spreading from the delivery site, AAV transduction and transgene expression, or the immune profiles of AAVs still concentrates a lot of efforts worldwide. Many are focused on modifying the capsid at a genomic level to meddle with epitopes involved in cell tropism. Such genetic mutations, however, can destabilize AAV formation, negatively affecting downstream processes and production titers. And in any case, such genetic variants warrant the development of a dedicated CMC process, which can considerably slow the translation of a therapeutic vector to the clinic. The AAV-Ligand Conjugate (ALIGATER™) platform is a robust alternative to capsid genetic engineering, which relies on the chemical conjugation of small, functionalizing ligands at the surface of the AAV capsid. As it requires no prior genetic intervention and is performed on AAV post production, this platform can be applied easily to virtually any natural or engineered AAV serotype. Here, we demonstrate that ALIGATER™ is particularly exciting for applications in the central nervous system (CNS). Building on our initial results with conjugated AAV (coAAV) vectors, showing improved brain distribution and transduction following intra parenchymal delivery in both rodents and non-human primates (NHP), we investigated the performance of coAAVs in the brain when administered directly into the cerebrospinal fluid (CSF) - a safer delivery procedure than the one tested before. To this end, we built a library of coAAVs and performed a parallel evaluation of these vectors with AAV9 in the NHP brain following intra-cisterna magna (ICM) delivery. Whereas AAV9 is considered as one of the best-in-class serotypes to effectively transduce the brain via this RoA, some serious adverse events have been reported following its use in both primate studies and clinical trials. Safety concerns were largely linked to dorsal root ganglion (DRG) and liver toxicities, resulting from elevated transduction and transgene expression levels in organs. In this study, we showed that at equivalent doses, several coAAVs presented biodistribution and transduction profiles comparable to AAV9 in the brain, while displaying low levels of transduction and transgene expression in the DRGs and most peripheral tissues. These results thus demonstrate that ALIGATER™ is a safe and efficient platform for neurological applications. It can be used to generate strong and robust proof of concept studies in small animals with good translatability to larger animals, accelerating the development of safe therapeutic vectors for neurological disorders.

1100 Development of De Novo Mining Platform for Discovery and Identification of Novel Small Class II CRISPR Nucleases with Expanded PAM Preference

Bang Wang[1], Nicola W. Y. Wong[1], Miao Yu[2], James Liu[1], XiangYong Oong[1], Lawrence Ip[1], Doris Man[1], Chloe Chen[1], Ken Chau[1], Hoi Yee Keung[1], Zongli Zheng[2]

[1]GenEditBio Limited, HongKong SAR, China,[2]Ming Wai Lau Centre for Reparative Medicine, Karolinska Institutet, HongKong SAR, China

Clustered regularly interspaced short palindromic repeats and associated proteins (CRISPR-Cas) system holds great promise to revolutionize genome editing and therapy in basic and translational settings. Various CRISPR-Cas systems have been explored and engineered, such as CRISPR-Cas9 and CRISPR-Cas12a that belong to the Class 2 of CRISPR-Cas system. However, *in vivo* applications of these tools remain limited in certain delivery methods due to their relatively large payload size, PAM restrictions and potential off-target effects. To address these challenges, we mined an extensive genome-resolved metagenomics database and identified an array of novel CRISPR effectors (300 to 700 amino acids) from natural environments. We streamlined the pipeline of predicting and identifying crRNA and tracrRNA from CRISPR operon by RuvC domain-based Hidden Markov Models and small RNA-seq, respectively. We also developed a robust screening method in mammalian cells for rapid identification of the recognizable PAM of each Cas effector. Our platform uncovered dozens of novel Cas nucleases with diverse PAM preferences. We selected one representative Cas (referred as GEBxII305) and engineered both the protein and single guide RNA based on the modeled R-loop complex structure. The engineered GEBxII305 shown a non-T-rich PAM preference and the on-target editing potency was dramatically

improved by up to 10 folds across 20 loci in human cell lines, HEK293T and HepG2. We combined the engineered GEBxII305 with optimized nuclear localization sequence (NLS) to further increase the genome editing efficiency to nearly 20 folds compared to the original version. Off-target profiling of the engineered GEBxII305 by GUIDE-Seq showed comparable levels of off-target effects in human genome with those well-documented CRISPR-Cas nucleases. We further applied the engineered GEBxII305 to primary cells, such as primary human hepatocytes and T cells, demonstrating its robust editing efficiencies. Taken together, we show that these novel Cas nucleases discovered by our platform are potent, specific, and have translational potentials for broad use in cell and gene therapy development.

1101 Intelligent Phage-Assembled Gene Expression (iPhAGE) System: A Novel Platform for Safe Nonviral Gene Therapy

Shirley Wong[1], Roderick A. Slavcev[2]

[1]Biology, University of Waterloo, Waterloo, ON, Canada,[2]School of Pharmacy, University of Waterloo, Waterloo, ON, Canada

Small molecules of DNA known as plasmids are found naturally in bacteria. Engineered plasmids can be powerful tools to transfer genes between different organisms. However, plasmids carry elements necessary for replicating in bacteria, which are superfluous and even detrimental for gene transfer or gene therapy applications in humans or animals. Plasmid backbone prokaryotic DNA encoding antibiotic resistance genes, origins of replication and other genetic elements and sequences recognized by the mammalian immune system can interfere with the expression, redose-ability and durability of the transferred gene. The phage M13 is a simple virus that specifically infects the bacterium *Escherichia coli*. Since phages like M13 cannot infect nor replicate in animal cells, they have immense potential as safe vectors for ferrying DNA cargo of virtually unlimited capacity in humans and have even been shown to cross the blood brain barrier. We examined how M13 can be used to improve plasmid vectors for gene therapy by generating "miniphagemids" lacking the problematic bacterial DNA. We constructed a plasmid that split up phage replication signals such that a gene of interest (GOI) cistron cassette could be inserted between them. Replication by M13 then produced virus particles only carrying the genes of interest without the rest of the plasmid. Despite the modifications, miniphagemid yield was comparable, if not superior, to that of wild-type "wildtype" phagemids with unmodified, intact replication regions. Hence, we demonstrated an elegantly simple approach for highly efficient production of gene delivery minivectors using phage M13. To improve the efficiency of miniphagemid production in absence of contaminating helper phage we further produced a novel and highly effective helper plasmid that fully complemented necessary M13 replication and structural components without any active contaminating plasmid packaging in presence or absence of the phagemid construct. We then characterized the capacity of miniphagemid particles for gene transfer into mammalian cell lines in vitro. As a targeting proof of principle, phage display of epidermal growth factor (EGF) was fused to pIII and enabled targeting of cells that overexpress the EGF receptor. Hybrid EGF-displaying phagemids encoding the *luc* reporter gene were transfected across $EGFR^+$ and $EGFR^-$ mammalian cell lines. Gene expression was assessed by examining resultant luciferase activity. EGF-displaying miniphagemids improved gene expression up to three times over full-length phagemids across different types of human cells suggesting the potential for an in vivo targeted gene delivery application of these miniphagemids. In conclusion, we demonstrated that phagemid miniaturization improves gene expression in human cells without detrimental impact on vector production. We also showed that phagemid miniaturization can be combined with phage display, a powerful technique to modify phage properties, such as enabling it to target human cells. This 'intelligent Phage-Assembled Gene Expression' (iPhAGE) system was not impaired in production by the separation of f1 *ori* domains and, in fact, led to superior rescue of miniphagemids by the helper plasmid and iPhAGE vectors also enhanced phage-mediated gene delivery in receptor-specific manner. Overall, we present here a novel targeted gene delivery platform based on the bacterial virus M13, showcasing its immense flexibility as a therapeutic platform. This technology is currently being extended to also generate linear covalently closed dsDNA targeted miniphagemids.

1102 Non-Human Primate Pharmacology of AAV Gene Therapy Vectors for Hereditary Angioedema

James Fleming[1], Theresa A. Towle[1], Jatin Narula[2], Arpana Khatri[1], Ting-Wen Cheng[1], Kevin Xuong Vinh Le[1], Joseph Palandra[3], David W. Souza[1], Lujain Al-Sowaimel[1], Marla Bazile[1], Sagar Patel Nisraiyya[1], Alexandra Srnka[1], Hongru Zhou[1], Abdulhafiz Imam Aliagan[2], Sumana Choudhury[4], Kristine Manibog[4], Naoko Murakami[4], Diana Sapashnik[2], Kimberly Zaraspe[4], Ricardos Tabet[1], Lisa R. Keyes[4], Sheila Rao-Dayton[4], Annette Sievers[2], Joanne Brodfuehrer[2], Sarah H. Lopes[5], Michael W. Bolt[6], Sury Somanathan[1], Marko J. Pregel[1]

[1]Rare Disease Research Unit, Pfizer Inc, Cambridge, MA,[2]Biomedicine Design, Pfizer Inc, Cambridge, MA,[3]Biomedicine Design, Pfizer Inc, Andover, MA,[4]Biomedicine Design, Pfizer Inc, Morrisville, NC,[5]Drug Safety R&D, Pfizer Inc, Groton, CT,[6]Drug Safety R&D, Pfizer Inc, Cambridge, MA

Adeno-associated viruses (AAVs) show promise as gene delivery vectors for genetic diseases including hemophilia A and B, Duchenne muscular dystrophy, and spinal muscular atrophy. Hereditary angioedema (HAE) is a rare genetic disorder characterized by swelling attacks that occur in cutaneous and submucosal tissues. HAE types 1 and 2 are caused by mutations in *SERPING1*, which codes for C1-INH protein. Deficiency of functional C1-INH, a serpin superfamily protease inhibitor, results in the production of excess bradykinin, the biological mediator of swelling. Liver is a major source for the production of C1-INH protein, and therefore a gene therapy approach in which AAV transduction of hepatocytes results in *SERPING1* transgene expression and secretion of C1-INH protein into the circulation appears feasible. A major challenge to this therapeutic approach is the very high levels of serum C1-INH anticipated to be required for therapeutic benefit. Modeling work from C1-INH replacement therapies provides an estimate of the expression level required to render 85% of patients attack free. While achieving such levels of secreted protein using AAV has proven feasible in mice, species differences in vector tropism have made it challenging in more clinically-relevant species such as non-human primates. To

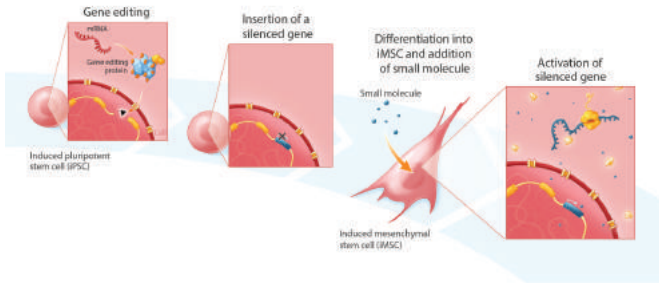
evaluate feasibility of a gene therapy as a therapeutic approach in HAE patients, AAV vectors designed to produce therapeutic levels of serum C1-INH expression at clinically-relevant dose levels were generated and evaluated in non-human primates (*Macaca fascicularis*). One-time intravenous doses resulted in serum C1-INH levels in NHPs above the predicted clinically-efficacious C1-INH level and above the normal human C1-INH level, suggesting that AAV vectors may have promise for gene therapy of HAE types 1 and 2.

1103 Efficient Transgene Knock-In in Human iPS Cells Combined with Small Molecule-Mediated "On-Switch" Yields Clonal Populations of Engineered Tissue-Specific Cells

Taeyun Kim, Ismet Caglar Tanrikulu, Christopher B. Rohde, Matthew Angel

Factor Bioscience Inc., Cambridge, MA

Mesenchymal stem cells (MSCs) are a promising cell-therapy platform with the potential to treat a diverse array of diseases due to their immunomodulator properties - properties which can be enhanced through gene editing. Gene editing autologous or donor-derived MSCs is challenging due to the non-clonal nature of these cell sources, and associated risks of off-target effects. In contrast, iPS cells, which are clonal and highly expandible, provide an ideal source of cells for gene editing and subsequent differentiation into tissue-specific cells for cell therapy applications. Here we establish stable clonal human induced pluripotent stem (iPS) cell lines engineered to express green fluorescent protein (GFP) using two different promoters. We then differentiate the engineered iPS cells to MSCs (EiMSCs) while monitoring changes in GFP expression, isolate an EiMSC subpopulation and verify differentiation using surface markers. Single-stranded DNA (ssDNA) donors encoding GFP under the control of the JeT or EF1α promoters were inserted into iPS cells using mRNA encoding UltraSlice gene-editing proteins targeting the AAVS1 safe-harbor locus. GFP transgene insertion rates of 40% and 10% were observed for JeT and EF1α promoter-containing donors, respectively. While EF1α and JeT promoters drive robust GFP expression when inserted directly in iMSCs, in iPS cells strong GFP expression was only observed under EF1α - expression was not detected in JeT-GFP iPS cells. Clonal cell lines were generated from both lines using single-cell deposition, and bi-allelic insertion into the AAVS1 locus was verified by amplicon sequencing. Engineered iPS cells were differentiated into EiMSCs, and GFP expression was monitored. During differentiation, the number of GFP-expressing cells decreased from >99% in the starting EF1α-GFP iPS cells to 40% in the differentiated EF1α-GFP iMSCs. In contrast, JeT-GFP iPS cells began expressing GFP during differentiation, but stopped expressing GFP near the end of the differentiation process. Treatment with Trichostatin A, a selective histone deacetylase (HDAC) inhibitor, resulted in a temporary increase in GFP expression in JeT-GFP cells during differentiation. To obtain a clonal population of EiMSCs that uniformly express GFP, we then enriched the GFP-expressing EF1α-GFP iMSCs, resulting in a cell line that exhibited traditional MSC surface markers (positive markers: CD90, CD73, CD105, and CD44; negative markers:CD34, TRA-1-60, TRA-1-81, CD45, and HLA-DR) and displayed stable GFP expression for over 7 passages. Here we demonstrate a platform for developing clonal EiMSC cell populations that uniformly and stably express a desired protein from a transgene inserted into a defined genomic locus by mRNA gene editing. We also show temporal control of transgene expression using small molecules during directed differentiation of iPS cells. This platform benefits from high knock-in efficiency enabled by mRNA gene editing combined with ssDNA donors and may prove useful for the development of cell therapies engineered to express therapeutic proteins.



1104 Therapeutic Transgene Levels Can Be Achieved by *In Vivo* Selection of Randomly Integrated rAAVs

Amita Tiyaboonchai, Anne G. Vonada, David Enicks, Markus Grompe

Pediatrics, Oregon Health and Science University, Portland, OR

Liver targeted recombinant adeno associated viruses (rAAV) typically have only a short therapeutic benefit when administered to neonatal or pediatric patients. This is due to their predominantly episomal expression that is lost during cell divisions as the child grows. While rAAVs can persist through multiple rounds of cell division by random integration into the genome, these integration events are rare and too infrequent to reach the therapeutic threshold of transgene expression required for successful gene therapy. We hypothesized that in vivo selection of targeted hepatocytes would allow these random integration events to reach a therapeutic threshold. We have previously developed a pharmacologically selectable shRNA that can expand a small population of hepatocytes in the liver with the desired gene edit in vivo. This shRNA functions by blocking expression of Cytochrome p450 reductase (Cypor) which is required for the metabolism of the drug acetaminophen to a hepatotoxic byproduct. Accumulation of this hepatotoxic byproduct leads to cell death. By creating a loss of Cypor linked to the desired gene edits, therapeutic cells can no longer metabolized acetaminophen and are protected from toxicity when high doses are administered. rAAVs containing a U6-driven shRNA targeting Cypor as well as a CAG promoter driving a human Factor IX (hFIX) transgene was delivered into wildtype neonatal and adult mice. Mice were then treated with acetaminophen. Immunofluorescent staining of the liver for Cypor shows large areas of clonal expansion of Cypor-negative hepatocytes, demonstrating successful selection of hepatocytes containing rAAV integrations. Because the rAAV construct expresses the shRNA in cis with hFIX, we would expect these Cypor-negative hepatocytes to also be hFIX positive. Interestingly, we observe both hFIX positive and negative clonal expansions among the Cypor negative hepatocytes. This suggests a rearrangement of the rAAV either during

rAAV production or integration of the vector into the hepatocytes. The composition and location of these rearrangements and their integrations will be further assessed by long read sequencing, which will serve to elucidate the nature of random rAAV genomic integrations. As a control for the randomly integrating vector, selectable vectors with arms of homology directing integration to one of two rAAV integration hotspots (the Albumin gene or the 28S ribosomal RNA locus) were also created. Mice treated with these vectors and subsequent selection will also be analyzed, and the proportion of on target to random integrations will provide additional insight on the integration preferences of rAAV vectors.

1105 Generating a Sheep Model and Developing a Gene Therapy for Sialidosis

Jillian Gallagher[1], Judith Gallant[2], PIng Xu[2], Rachael Gately[3], Rachel Prestigiacomo[1], Abby McElroy[1], Erin Frances Hall[1], Hector Ribeiro Benatti[1], Leigh Fremuth[4], Diantha Van de Vlekkert[4], Huimin Hu[4], Camilo Toro[5], Cynthia J. Tifft[5], Scot A. Wolfe[6], Jaime Rivera[2], Alessandra D'Azzo[4], Miguel Sena Esteves[7], Heather Gray-Edwards[1]

[1]Horae Gene Therapy Center, UMass Chan Medical School, Worcester, MA,[2]Department of Pediatrics, UMass Chan Medical School, Worcester, MA,[3]Cummings School of Veterinary Medicine at Tufts University, Grafton, MA,[4]Department of Genetics, St. Jude Children's Research Hospital, Memphis, TN,[5]Medical Genetics Branch, National Institutes of Health, Bethesda, MD,[6]Department of Molecular, Cell and Cancer Biology, University of Massachusetts Chan Medical School, Worcester, MA,[7]Department of Neurology, UMass Chan Medical School, Worcester, MA

Sialidosis is a lysosomal storage disease caused by mutations in the *NEU1* gene that encodes the lysosomal sialidase neuraminidase 1 (NEU1). Deficiency of NEU1 causes accumulation of sialylated glycopeptides and oligosaccharides in tissues and body fluids, resulting in cell and organ dysfunction. Sialidosis has two forms the late onset Type I or early onset Type II. Normosomatic, Type I patients have adolescent onset with action myoclonus, progressive ataxia, seizures, cherry-red spot, and progressive loss of vision. Symptoms of Type II infantile/juvenile patients are more severe, including hepatosplenomegaly, coarse facial features, dysostosis multiplex, developmental delay, and a short life expectancy. Currently, there are no approved therapies for sialidosis. Our team has developed an AAV-mediated gene therapy strategy to treat sialidosis in small and large animal models. We have developed three AAV9 vectors encoding NEU1, alone or with cathepsin A (CTSA), and either encoding native NEU1 or with modifications to enhance stabilization and secretion. Initial testing of intravenous injections in wild type (WT) mice showed significantly increased NEU1 expression and enzymatic activity ranging from 4 to 40-fold over control mice in the liver and kidney, showing proof of concept and safety. Preliminary results of neonatal intracerebroventricular injections in NEU1 knockout (KO) mice show a higher body weight at weaning age, (n=12) when treated with either of the three vectors (14g- 15g, SD<1.5) compared to untreated mice (11g, n=3, SD=1). Additionally, increased weight of treated NEU1-KO mice is comparable to treated (n=19) and normal control mice (n=10) (15-17g, SD<1.5). Future experiments including behavioral testing to assess memory, cognition, and motor abilities, enzyme assays, biodistribution, and histology will also help determine the most efficacious vector design. The safest and most efficacious vector will be further optimized using a large animal model of sialidosis that we generated using CRISPR-Cas9 technology. Early-stage sheep embryos were electroporated with SpCas9 and RNA guides from exon 5 and 6 of *NEU1*. Genome edited embryos resulted in lambs with NEU1 activity ranging from 0-56% of normal and a phenotype associated with Type II sialidosis, presentation includes head tilt, nystagmus, vacuolated distended neurons, cerebral hemorrhage, hepatosplenomegaly, severe spine curvature, bone deformities, bladder dysfunction, and blindness. To minimize neonatal lethality, we selected a sheep with a Type I patient-like mutation (A319V) and expect homozygous affected sheep in late spring. We have also used double-stranded DNA (dsDNA) donor templates with our current CRISPR-SpCas9 strategy to generate humanized point mutations for Type I (P316S) and Type II (F260Y) sialidosis in additional sheep models. Experiments using dsDNA templates in sheep embryos produced ~80% dsDNA template insertion efficiency, and embryos with the dsDNA template will be implanted in mid-February 2023. Altogether, these studies in parallel with natural history studies in sialidosis patients will inform future clinical trials for this devastating disease.

1106 AAV Serotype Difference in Dose-Dependent Modes of Entry to Cardiomyocytes

Jenifer M. Vasquez, Caner Günaydin, Hailey C. Lephart, Miguel de Mulder Rougvie, Philip L. Leopold, Ronald G. Crystal

Department of Genetic Medicine, Weill Cornell Medicine, New York, NY

AAV9 (clade F), AAVrh.10 (clade E) and AAV6 (clade A) have each been shown *in vitro* and *in vivo* to have tropism for cardiomyocytes following intravenous administration. Based on knowledge that the first step of AAV interaction with cells is through binding to a cell surface receptor, while each of these serotypes are cardiotropic, we asked: are there similarities or differences in what these serotypes use to interact with cardiomyocytes? To investigate this, we compared the interaction of AAV9, rh.10 and 6 with 2 human cardiomyocyte cell lines, T0539 and AC16. At each of the same doses ($2x10^3$, $2x10^4$ and $2x10^5$ genome copies/cell), AAV6-mediated expression of the β-galactosidase marker gene was 10-fold higher than AAV9 or rh.10, suggesting that AAV6 may use a different mode of entry to cardiomyocytes than AAV9 or rh.10. Based on prior studies of cell populations other than cardiomyocytes, we focused on the interaction of each serotype with receptors AAVR (KIAA0319L), the type I transmembrane receptor used by most AAV serotypes, and sialic acid, identified as a primary or coreceptor for some serotypes. The contribution of AAVR to AAV infection in cardiomyocytes was assessed by (1) blocking of AAVR using an anti-AAVR monoclonal antibody; and (2) upregulation of AAVR by transfection with a plasmid expressing an AAVR cDNA. In the anti-AAVR blocking experiments, anti-AAVR was able to reduce gene transfer by AAV9 and AAVrh.10 to T0539 or AC16 cells by at least 90% ($p<0.05$ for both comparisons). In contrast, anti-AAVR did not cause a significant decrease in AAV6 gene delivery to either T0539 cells or AC16 cells ($p>0.1$). In receptor upregulation experiments, exogenous expression of AAVR more than doubled βgal expression mediated by

both AAV9 and AAVrh.10 in T0539 and AC16 cells ($p<0.01$ for both comparisons). In contrast, exogenous expression of AAVR failed to produce a significant increase in AAV6-mediated gene expression in both cell lines. To assess sialic acid dependence, T0539 cells and AC16 cells treated with neuraminidase to remove sialic acid led to a reduction in AAV6-mediated βgal expression in T0539 (93±1%, $p<3x10^{-6}$) and AC16 cells (91±2%, $p<3x10^{-8}$). In contrast, neuraminidase treatment resulted in a significant increase in AAV9- and AAVrh.10-mediated gene expression in both T0539 and AC16 cells ($p<0.01$, for both lines). Consistent with the studies in the cardiac cell lines, the dependence of AAV9, rh.10 and 6 on AAVR was confirmed by comparing infectivity of HeLa cells and HeLa-AAVR-knockout (HeLa-KO) cells. AAV6 infection of HeLa cells showed a dose-dependent increase in βgal expression ranging from $2x10^3$ to $2x10^6$ gc/cell. In contrast, AAV6 infection of HeLa-KO cells showed no expression at the lowest doses ($2x10^3$ and $2x10^4$ gc/cell) but dose-dependent expression was observed at higher doses ($2x10^5$, $2x10^6$ gc/cell). By comparison, AAV9 and AAVrh.10 showed dose-dependent infection of HeLa cells but no βgal expression at any dose in HeLa-KO cells. Regarding sialic acid dependence, following treatment of HeLa cells with neuraminidase, βgal expression mediated by AAV6 was reduced by 92 ± 4.3% ($p<3x10^{-4}$). In summary, while AAV9- and AAVrh.10-mediated transduction of cardiomyocytes is highly dependent on AAVR, AAV6 transduction of cardiomyocytes is highly dependent on cell-surface sialated molecules.

1107 Online Monitoring of Cell Growth and Shape in Transient Transfection Process for AAV Production in Stirred Tank Bioreactor

Eric Karengera[1], Ariane Bricteux[1], Anna Doshina[1], Thomas Bouckenooghe[1], Emilie Gateau[1], Emeline Puissant[2], Damien Cabosart[2], Hanna P. Lesch[1]

[1]Exothera, Jumet, Belgium,[2]Ovizio, Uccle, Belgium

While cell and gene therapies (C&GT) are gaining traction in the clinic with some notable successes, the manufacturing process for these therapies remains challenging and costly. The transient production of viral vector used in C&GT, such as Adeno Associated Virus (AAV), is dependent on consistent upstream processes for batch-to-batch reproducibility. Such consistency is made possible with proper access to process parameters like viable and total cell densities. The iLine Pro F (Ovizio) is an automated cell analyzer to monitor cellular dynamics through on-line bioreactor connection. It relies on a combination of quantitative phase imaging for label-free cell identification and feature extraction algorithms for measuring 30+ parameters for each individual cells such as diameter, elongation, membrane regularity. These parameters are then combined through machine learning algorithms to compute total and viable cell densities. The continuous stream of data provided enables better decision-making during transfection and production phases. We evaluated the iLine F Pro as a tool for real-time HEK293 culture monitoring in manufacturing scale bioreactors for an AAV product. For comparison, the cell density was also monitored off-line using the Vi-CELL counter (Beckman). The data was processed to optimize a raw version of Ovizio's algorithm to a final version based on historical data set. A good correlation between cell densities and viabilities was obtained with the iLine F and the Vi-CELL XR for un-transfected and transfected cells. The developed algorithm can be used for new experiments to replicate the Vi-CELL counts in a label-free and on-line manner. The frequent measurements of the iLine F PRO (1 every hour) can be leveraged to predict when the target cell concentration for transfection will be reached. Pilot tests showed promising results on the accuracy of a predicting algorithm to determine target cell concentration for transfection. This represents an interesting approach to optimize planning of transfection reagent mix preparation. After transfection, a new cell population presenting morphological properties that could correspond to transfected cell population was identified. Monitoring of this population would allow access to transfection efficiency in real-time. As a conclusion, we highlighted the high potential for online monitoring of the cell culture as a tool to increase process understanding, crucial during development stage, and as a first step toward process automation.

1108 Optimization of Chitosan-Lipid Hybrid Nanoparticles for mRNA Delivery

Bianca Bonetto Moreno Garcia[1,2], Stefania Douka[2], Omar Mertins[1], Enrico Mastrobattista[2], Sang Won Han[1]

[1]Department of Biophysics, Federal University of São Paulo (UNIFESP), São Paulo, Brazil,[2]Department of Pharmaceutics, Utrecht University, Utrecht, Netherlands

Introduction: Gene therapy based on messenger RNA (mRNA) has emerged as a powerful tool due its high efficiency and wide range of therapeutic applications such as protein replacement, genome editing, vaccines, and immunotherapies. Compared with plasmid DNA (pDNA) for gene therapy, mRNA has several advantages: protein expression is faster because it does not need to cross the nuclear barrier, mRNA synthesis is relatively quick, and mRNA vectors are safer than pDNA vectors as they do not integrate in the host genome avoiding mutagenesis. However, the success of mRNA therapy depends on the design of safe and efficient gene carries that protect it from RNAses and deliver efficiently to target cells. Recently, we synthesized chitosan-lipid hybrid nanoparticles (named chitosomes) with DOPE/DOTAP surfactants and arginine-modified chitosan (CH-Arg) which showed a highly efficient transfection rate with pDNA. Here, we aimed to evaluated physicochemical properties of chitosome-mRNA complexes and efficiency of mRNA delivery. **Methods:** Different chitosomes were prepared by the association of DOPE/DOTAP lipids and CH-Arg by reverse phase evaporation technique, and after these were complexed with mRNA expressing EGFP. Dynamic light scattering (DLS) and zeta potential (ZP) techniques were used for chitosome and chitosome-mRNA characterization, and agarose gel electrophoresis was performed to assess the efficiency of complexation. *In vitro* transfection was assessed by the fluorescent green protein (GFP) expression in HEK293T cells by fluorescence microscopy and flow cytometry, and cytotoxicity was also assessed by flow cytometry. **Results:** At the optimal ratio concentration (8:1 chitosome:mRNA), chitosomes had small size (75.0 ± 3.6 nm), low polydispersity (0.272 ± 0.040) and positive charge (+28.7 ± 2.8 mV) and were able to fully complex with mRNA, as shown by agarose gel electrophoresis and decrease of charge (+12.0 ± 3.1 mV). However, the complexes chitosome-mRNA showed big size (1772.5 ± 236.2 nm) and high polydispersity (0.505 ± 0.293). After 24 hours of transfection the efficiency was 32.9% ± 5.3 but, interestingly, after 48 hours the transfection efficiency increased (65.85% ± 5.31) and showing a good cell viability (69.3% ± 6.5). **Conclusions:** Taken together, the results show that chitosomes are efficient to stably complex with mRNA

and to deliver to HEK293T cells. Further optimization of the chitosome structure and its complexation with mRNA can further increase the mRNA delivery capacity, making the chitosome a promising system for gene therapy applications. **Funding Support:** FAPESP: 2022/04361-7, 2020/06913-1, 2015/20206-8; CNPq: 303646/2019-5

1109 Oncogenic Extrachromosomal DNA Targeting and Detection Using CRISPR Technology

Mei-Wei Lin

Industrial Technology Research Institute, Hsinchu, Taiwan

Metastases account for the great majority of cancer-associated deaths. Intratumoral heterogeneity contributes to cancer drug resistance, so the elucidation of underlying mechanisms is very important for controlling the growth and spread of primary tumors. Extrachromosomal DNA (ecDNA) was early described as "double minute" and recent studies unveiled that ecDNA is primary source of oncogene amplification in tumor cell. ecDNA was found in nearly half of human cancers but it was almost never found in normal cells, which shows that ecDNA is tumor-specific. Integrating ultrastructural imaging, long-range optical mapping and computational analysis of whole-genome sequencing revealed ecDNA contains highly accessible chromatin where ecDNA drives massive oncogene expression. CRISPR is the immune system in bacteria to defend against invading nucleic acids and has been repurposed for DNA and RNA editing. In this study, we will use two CRISPR system (Cas3 and Cas12) for ecDNA targeting and detection, respectively. Generating a spectrum of large genome deletions render Cas3 potential in ecDNA destruction. We first proposed to target ecDNA with Cas3. In addition, Cas12 is used for DNA detection due to the collateral effect. Development of ecDNA detection using cas12 will facilitate cancer diagnosis. Furthermore, autophagy is a catabolic process aimed at recycling cellular components and damaged organelles in response to diverse conditions of stress. Activation of cell autophagy has shown to reduce the dysregulated DNA amplification and inhibit tumor progression. Collectively, exploit of CRISPR system and autophagy activation in ecDNA detection and elimination pave a new avenue for cancer therapy.

1110 Case Study: Development and Scale-Up of a Helper Dependent Adenovirus (HDAd) Process Using the iCELLis Bioreactor Platform

Brian Gardell, Scott Gatto, Denis Kole

Pall Corporation, Westborough, MA

Viral vectors are currently the preferred gene-delivery vehicle for most cell and gene therapies and clinical trials require high titer virus preparations to adequately deliver the therapeutic transgenes to clinical subjects or target cells. For this reason, technologies that enable the industrialization of these processes in a safe, robust, and cost-effective way are necessary to support the demands of the patient population. However, complexity around developing and scaling viral vector processes to commercial manufacturing scale, and the lack of standardized approaches remain as challenges that can impact therapy development timelines and productivity. Selection of the appropriate production platform plays a key role on the successful implementation of a process that meets the commercialization timelines and manufacturing costs. We will share a case study that demonstrates the successful steps taken to develop and scale up a customer process for a Helper-Dependent-Adenovirus (HDAd), leveraging Pall's process expertise, and the iCELLis* bioreactor platform, to help accelerate the development timelines. Critical process parameters for development and manufacturing, such as seeding density, infection density, and harvest strategy, were first tested at the flatware stage, and continually optimized over the course of the iCELLis Nano development stage. The optimized parameters were used successfully in duplicate scale-up batches at the iCELLis 500+ scale to demonstrate a process ready for transfer to a clinical manufacturing facility. *registered trademark

1111 Placental-Derived Mesenchymal-Like Adherent Stromal Cell (MLASC) Therapy Results in Alterations in Gene and Protein Signatures Associated with Inflammation and Fistula Formation in Patients with Crohn's Disease

A. Kilcoyne[1], S. Koppisetti[1], B. Glover[1], W. VanDerTouw[1], C. Daly[1], V. Jankovic[2], R. Hariri[1]

[1]Celularity, Florham Park, NJ,[2]Regeneron, Tarrytown, NY

Background: Crohn's disease (CD) is a chronic inflammatory bowel disease. The treatment goal is to control inflammation, induce clinical remission and reduce the incidence of fistulae. Fistulae, caused by epithelial-to-mesenchymal transition (EMT), occur in up to 50% of patients. Transforming growth factor-beta (TGF-β) is an important inducer of EMT by regulating loss of epithelial and gain of mesenchymal markers. Clinical remission rates of 50% at 2 years were observed in 3 early phase studies of IV MLASC therapy in moderate-to-severe CD. To understand the mechanisms of response to MLASC therapy, gene expression and proteomics data was generated to detect clinical response signatures, identify mild/severe CD pathways, and identify changes associated with fistula formation. **Methods:** 2 groups evaluated: MLASC responders (N=12) and controls (N=12) at 3 time points: visit 3 (baseline), visit 4 (early post-treatment) and visit 7 (later post-treatment). Patients were profiled from peripheral blood using transcriptomics/proteomics platforms. Transcriptomics data characterized gene expression in cells of whole blood; Proteomics data characterized protein in plasma. To understand significance of expression changes, pathways enriched in the differentially expressed genes (DEGs) and proteins (DEPs) were identified. Specific DEGs and DEPs that are known to be related to fistula formation were measured.**Results**: MLASC treatment resulted in change in gene and protein signatures trending to gene upregulation and protein down regulation. Numbers of genes/proteins were found to be significantly associated with clinical response (table 1). At visit 4, genes upregulated in MLASC vs placebo were responsible for cell cycle/proliferation and immune response. By visit 7, down-regulation of immune response and inflammation-related genes was observed in MLASC patients, suggesting a therapeutic effect. 113 DEPs were significantly correlated with disease severity. DEGs associated with mild disease were related to immune response and inflammatory markers - primarily to interferon-mediated immune response. Considering fistula formation, increased DEGs expression responsible for immune cell signaling and growth

factor signaling (HGF, PI3K and AKT) was observed. DEGs decreased were responsible for TGF-β, Th2 T-cell response and TNFα signaling suggesting a transition from a fistulizing state. Between visit 3 and 4, in the MLASC patients, repression of plasma proteome markers associated with EMT were observed (Figure 1). **Conclusion:** In CD, MLASCs resulted in alterations in gene and protein signatures associated with inflammation and fistula formation. This analysis provides insight into pathways associated with severity of CD and suggests that gene and protein profiling of blood plasma might be useful for assessing disease severity and treatment response and also suggests that MLASC's may have potential in limiting fistula formation and warrants further evaluation.

	Timepoint	Direction of gene/protein regulation	Transcriptomics	Proteomics

1112 Method Development and Validation of a One-Step Duplex RT-qPCR Assay for Analysis of RAAV Vector-Derived Gene Expression in Cynomolgus Monkeys

Allison Swarthout[1], Kristin N. Bell[1], William Chappell[2], Mcpharlin Christopher[1], Jiewu Liu[2], Haiyan Ma[1]

[1]Northern Biomolecular Services, Kalamazoo, MI,[2]Kriya Therapeutics, Inc., Research Triangle Park, NC

Introduction: Demands for preclinical safety assessments of gene and cell therapy test articles have effectively increased the necessity for regulated vector biodistribution and vector-derived gene expression studies. Guidance documents issued from numerous international regulatory authorities recommend the use of quantitative polymerase chain reaction (qPCR) and reverse transcriptase qPCR (RT-qPCR) assays to analyze biodistribution and gene expression samples due to their highly sensitive and robust target-specific detection. Compared with qPCR, RTqPCR analysis of vector-derived gene expression is more complicated as additional parameters should be monitored. Viral vector genomic DNA contamination in RNA samples can affect overall data integrity, therefore RNA samples from the dosed animals should be tested by RT-qPCR both in the presence and absence of reverse transcriptase. RNA samples severely contaminated with vector DNA will require additional DNase I treatment(s) and reanalysis. RNA integrity should also be monitored as RNA is prone to degradation. Therefore, a selected reference gene(s) should be included in the validation. Currently, there is a complete lack of regulatory guidelines for RT-qPCR assay assessment to support vector-derived gene expression analysis. Consequently, the approach to conduct preclinical RT-qPCR method development, validation, and sample analysis can vary between bioanalytical scientists and laboratories based on their scientific interpretation. Regarding this need, we report the method development and validation of a one-step RT-qPCR assay for analysis of a recombinant AAV (rAAV) vector-derived transgene mRNA in cynomolgus monkeys and recommend parameters to evaluate during method development and validation. **Method Development, Results, and Conclusion:** Two sets of primers and probes were developed, one for rAAV genome detection and vector-derived transgene mRNA in the presence of monkey RNA, and the other for detection of endogenous reference monkey *HPRT1* mRNA. The primer and probe concentrations were optimized to meet the validation acceptance criteria. To account for inefficiencies that could occur in the mRNA to cDNA conversion process, a synthetic RNA oligo encoding the vector-derived mRNA sequence was utilized in all standard curves and quality controls (QC). Currently, vector DNA contaminated RNA undergoes a time-consuming manual repurification after additional DNase I treatment(s) which brings an associated risk of sample loss. In this study, several DNase I treatments not requiring additional purification were compared and optimized to avoid any inhibition on RT-qPCR. Our data demonstrated that TURBO DNase I removed approximately 99.9% of the spiked plasmid DNA in RNA samples while ezDNase only removed approximately 97-98% of the spiked plasmid DNA in the RNA samples. **Method Validation, Results, and Conclusion:** Five validation runs were performed with serially diluted RNA standards, negative controls, and QCs, plated in the presence of 100ng cynomolgus monkey liver RNA matrix. Each completed run met the validation acceptance criteria for target and reference gene mRNA amplification. The ULOQ, LLOQ, and LOD were 10^8, 50, and 25 single-stranded copies per reaction, respectively. Regardless of standard RNA concentration, little variation was seen in *HPRT1* Ct values among the same type of matrix RNA, showing that various amounts of target mRNA did not affect *HPRT1* gene amplification. Neither freeze-thaw cycling nor various reagent lots affected the validation run and no matrix effect was observed. The extensive evaluation of the fit-for-purpose validation parameters confirms the applicability of the RT-qPCR method for non-clinical studies of vector-derived gene expression.

1113 Gene Editing of R14del Mutation in PLN Rescues PLN-R14del-Associated Cardiomyopathy

Emma Xu, Max Levine, Shivani Thombare, Nidhi Nair, Melissa Van Pell, Jin Yang, Timothy Hoey, Kathryn N. Ivey, Huanyu Zhou

Tenaya Therapeutics, South San Francisco, CA

The Arg14del (R14del) mutation in the Phospholamban (PLN) gene is a common genetic cause of familial dilated or arrhythmogenic cardiomyopathy. PLN plays a crucial role in intracellular calcium

homeostasis of the cardiomyocyte by negatively regulating sarco/endoplasmic reticulum Ca2+-ATPase (SERCA). The R14del mutation creates a dominant active form of PLN and results in both super-inhibition of SERCA activity and PLN protein aggregation. PLN-R14del-associated cardiomyopathy has a poor prognosis, high adolescent mortality, and no effective therapy other than heart transplantation. In the last decade, CRISPR-Cas9 gene editing emerged to offer a potential new era of curing and preventing human genetic diseases. The ability to correct the specific pathogenetic driver underlying disease, the R14del mutation, through in vivo delivery of CRISPR-Cas9 components represents an exciting therapeutic frontier for addressing PLN-R14del-associated cardiomyopathy. Tenaya Therapeutics has developed a gene therapy designed to deliver both Cas9 and PLN-R14del-specific sgRNA from a single AAV vector. We first tested our gene editing therapy in patient-specific human iPSC-derived cardiomyocytes (iPSC-CMs) and found it precisely and efficiently edited the PLN-R14del allele without affecting the wild-type PLN allele. We further tested various doses of our PLN-R14del gene editing therapy in a well-characterized mouse model and found heart function of PLN-R14del mice were rescued to near wild-type levels. Our preclinical results suggest PLN-R14del gene editing may be a promising therapy for PLN-R14del-associated cardiomyopathy.

1114 Validation of a Platform Method for Quantification of Cell Lines

Andreas Alberti, Anandhakumar Jayamani, Stacie Fichthorn, Marian L. McKee

Eurofins BioPharma Product Testing, Lancaster, PA

Reliable quantification of viable cells is a critical aspect in the quality control of biopharmaceutical products during all drug lifecycle phases, including drug development, clinical investigation, process scale-up, GMP manufacturing, and batch release for patient use. Current challenges in the BioPharma industry include the routine execution of test methods that can provide quality data within a reasonable turnaround-time, while offering testing capabilities toward a variety of manufacturing cell lines and cell products in a setting governed by pharmaceutical regulatory requirements. As per the FDA Industry Guidance on CAR T Cell Products, it is crucial to develop and implement well-designed logistics, including the timing for sampling and testing for lot release due to the limited shelf life of these cell therapy products before product quality degrades. In addition, in-process controls such as cell viability have to be outlined in accordance with regulatory agency guidance on CMC for Human Gene Therapy Investigational New Drug Applications (IND). Considering the current biopharmaceutical needs and regulatory expectations, this study focuses on the validation of a platform method for quantifying total cell concentration, viable cell concentration, and viability on selected cell lines, using an automated cell counter. The validation strategy involves the evaluation of data with statistical parameters, which are critical to assess system suitability and demonstrate reliable testing performance according to its intended use. The ultimate goal of this work is to demonstrate a statistically based approach in the validation and establishment of an analytical method that can support time-sensitive routine testing and quantify cell lines that have biopharmaceutical relevance in the field of cell and gene therapy.

1115 Restoration of Auditory Function with Otoferlin Gene Transfer Therapy in Nonsense (Q828X) and Missense (pR1934Q and Deaf5) Models of Otof Deficiency

Background Otoferlin is a calcium sensor protein expressed in the inner hair cells and is important for proper synaptic transmission between inner hair cells and the afferent fibers of the spiral ganglion. Biallelic loss of function mutations in the *OTOF* gene lead to congenital severe-to-profound auditory neuropathy spectrum disorder (ANSD) in both humans (DFNB9) and in mice. DFNB9 is believed to be causal in 2-3% of individuals born with hearing loss. In human patients, numerous variants of *OTOF*-related deafness (DFNB9) have been identified. We previously demonstrated that *OTOF* gene transfer therapy can restore auditory function measured by Auditory Brainstem Response (ABR) in Q828X mutant mice that leads to nonsense mutation. Here, we compared the efficacy of *OTOF* gene transfer in additional mouse models carrying missense mutations to evaluate efficacy in a wider range of *OTOF* variants. **Methods** Three different mouse models of *OTOF*-related deafness were treated with dual hybrid AAV vectors encoding *OTOF*. Otof-Q828X is a mouse model of a cognate variant (p.Q829X) characterized in Spanish and Latin American populations (Migliosi et al. 2002; Rodríguez-Ballesteros et al. 2008). The p.R1934Q mouse model was developed as a model carrying a homozygous R1939Q variant that has been characterized in Korean population (Kim et al. 2018). Lastly, Deaf5 is a mouse model harboring an ENU-induced missense mutation resulting in a single base substitution in the exon 10 of in the mouse otoferlin gene (Longo-Guess et al., 2007). For all three groups, male and female mice were administered with dual AAV vectors around 4-6 weeks of age. Restoration of auditory function was assessed at 4 weeks after administration using auditory brainstem response to tone bursts over 4-32 kHz. Transgene expression was evaluated by anti-myc tag antibody staining of cochlea wholemount preparation to distinguish from endogenous Otoferlin. **Results** In all three DFNB9 mouse models with different variants of *Otof*, the majority of mice showed restoration of auditory function measured by improvement in ABR thresholds compared to vehicle treated control mice over the entire tested range (4-32 kHz). In all groups, over 50% of animals achieved ABR thresholds within the range observed in wild type mice. In addition, transgene expression patterns will be discussed.

Conclusion These results demonstrate that *OTOF* gene transfer therapy with dual hybrid AAV can restore auditory function in various *OTOF*-deficient situations in murine models and is likely to provide benefit for DFNB9 patients in wider populations.

1116 Optimization of AAV-Mediated Gene Therapy for the Accelerated Aging Disorder-Cockayne Syndrome

Monika Chauhan[1], Fatemeh (Ellie) Khadir[1], Audrey L. Daugherty[1], Ozgun Firat Duzenli[2], Jennifer A. Tinklenberg[1], Peter B. Kang[1], George Aslanidi[2], Christina A. Pacak[1]

[1]Department of Neurology and Paul and Sheila Wellstone Muscular Dystrophy Center, University of Minnesota, Minneapolis, MN,[2]The Hormel Institute, University of Minnesota, Austin, MN

Our goal is to optimize a clinically relevant gene delivery strategy for disorders caused by pathogenic variants in the classic Cockayne syndrome genes *ERCC6* and *ERCC8*, several xeroderma pigmentosum (XP) genes *ERCC2, ERCC3, ERCC4*, and *ERCC5* that can all lead to accelerated aging and neurodegeneration - a Cockayne syndrome (CS) phenotype. This study is designed to optimize adeno-associated virus (AAV) serotype, delivery route, promoter, and dose to target specific cell types and regions of the brain that are most relevant to the treatment of CS. Using a constitutive chicken β-Actin (CBA) promoter to drive expression of a luciferase transgene fused to YFP, we compared the following AAV delivery routes: intravenous (IV) $1x10^{13}$ vg/kg body weight, intrathecal (IT) $1x10^{12}$ vg/kg body weight, and intra-cerebroventricular (ICV) $1x10^{12}$ vg/kg total dose following bilateral administrations. All studies were performed in wild-type FVB/NJ mice. For each delivery route, we compared the transduction efficiencies of two capsids: AAV9 and AAV-DJ. Luciferase expression was confirmed through *in vivo* bioluminescence imaging at regular intervals throughout the eight week study. After eight weeks, mice were euthanized and full necropsies performed. Our evaluations thus far have shown the following: (ICV) AAV-DJ demonstrated significantly increased vector genome (vg) uptake in cerebellum, spinal cord, hypothalamus, and hippocampus as compared to AAV9 and RNA transcript expression analyses correlated well. (IT) AAV-DJ demonstrated significantly increased vg uptake in the cortex as compared to AAV9 and RNA transcript expression analyses correlated well. (IV) AAV-DJ demonstrated significantly increased vg uptake in cerebellum, spinal cord, hypothalamus, and hippocampus as compared to AAV9 and RNA transcript expression analyses is underway. Evaluations of other tissues and biodistribution assessments of protein expression within CNS cell types are ongoing. As an additional layer of control over expression can be conferred through promoter choice, we are evaluating a panel of existing promoters and novel mini-promoters to evaluate their relative efficacy. Information gained from these collective studies will guide the design of therapeutic vectors for CS.

1117 Development of Liver De-Targeted AAVrh74 Vectors with Increased Transduction Efficiency in Mouse Muscles Following Systemic Administration

Keyun Qing[1], Jakob Shoti[1], Geoffrey D. Keeler[2], Arun Srivastava[3]

[1]University of Florida, Gainesville, FL,[2]University of Florida, Gainesvile, FL,[3]University of Florida College of Medicine, Gainesville, FL

Solid Biosciences reported serious adverse events such as complement activation and thrombocytopenia causing renal damage and cardiopulmonary insufficiency in a gene therapy rial of Duchenne muscular dystrophy using AAV9 vectors. Pfizer, also using AAV9 vectors, reported several serious adverse events such as acute kidney injury involving atypical hemolytic uremic syndrome and thrombocytopenia, and the death of a patient. Sarepta Therapeutics reported vomitting as the only adverse event in 50% of patients using AAVrh74 vectors, indicating that these vectors are safer. However, in pre-clinical studies with mdx mice (*Hum. Gene Ther.*, 32: 375-389, 2021), greater than a log higher genome copy numbers of AAVrh74 vectors were sequestered in mouse liver than any other muscle tissues (gastrocnemius, tibialis anterior, triceps, quadriceps, and diaphragm), thereby limiting their availability for muscle transduction. We also observed abundant transduction of mouse liver with the AAVrh74 vectors injected intravenously in C57BL6/J mice at $1x10^{10}$ and $1x10^{11}$ vgs/mouse (in two different experiments), 2-week post-vector administration (**Figure 1A**). Thus, it is of paramount importance to develop strategies to de-target AAVrh74 vectors from the liver. In the present studies, we generated liver de-targeted AAVrh74 vectors based on a published study (*Sci Transl Med*, 12: 2020), in which liver-tropic AAV serotype vectors such as AAV2, AAV3, and AAV8, which contain a threonine (T) residue at position 265 within the variable region I (VR-I) of the capsid, were documented to play a key role in liver transduction. Since the T265 residue is also conserved in AAVrh74 (**Figure 1B**), using site-directed mutagenesis, we generated a T265-deletion mutant of AAVrh74 vector. WT- and T265del-AAVrh74-FLuc vectors were injected intravenously at $1X10^{12}$ vgs/mouse (n=5), and whole-body bioluminescence imaging was performed 2-weeks post-vector administration. As can be seen in **Figure 1C**, the T265del-AAVrh74 vectors were significantly de-targeted from the liver ($p<0.05$). More interestingly, the transduction efficiency of the T265del-AAVrh74 vectors was significantly increased in the muscle ($p<0.05$) (**Figure 1D**). The use of liver de-targeted capsid- and genome-modified optimized (Opt) AAVrh74 vectors may prove to be safe and effective in the potential gene therapy of human muscular dystrophies at reduced doses.

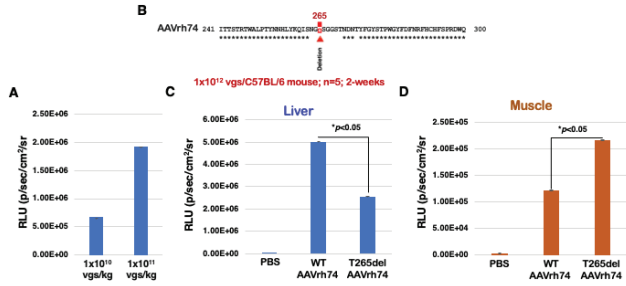

Figure 1: (A) Robust liver transduction with AAVrh74-CBA-FLuc vectors in C57BL/6 mice. **(B)** T265 is conserved in AAVrh74, and its deletion leads to significant liver de-targeting following intravenous delivery **(C)**, and a corresponding increased transduction of the mouse gastrocnemius muscle **(D)**.

1118 Preclinical Development of LYL119, a ROR1-Targeted CAR T-Cell Product Candidate Incorporating Four Novel T-Cell Reprogramming Technologies to Overcome Barriers to Effective Cell Therapy for Solid Tumors

Viola C. Lam, Jessica Barragan, Christina Cheung, Aileen Li, Jessica Briones, Purnima Sundar, Hajime Hiraragi, Shobha Potluri, Alexander Cheung, Rachel C. Lynn

Lyell Immunopharma, South San Francisco, CA

For solid tumor cell therapy to be effective, new strategies are needed to improve T-cell activation, persistence, and durable function. We have developed four stackable reprogramming technologies to address these issues: 1) genetic overexpression of the activator protein 1 (AP-1) family transcription factor c-Jun to reduce chimeric antigen receptor (CAR) T-cell exhaustion and improve functional activity; 2) nuclear receptor subfamily 4A (NR4A) gene knock-out (KO) because NR4A transcription factors may contribute to exhaustion and reduce T-cell function by limiting expression of AP-1-regulated genes; 3) Epi-R™ manufacturing protocols to promote stem-like characteristics; and 4) Stim-R™ technology, a synthetic cell mimic that presents anti-CD3 and anti-CD28 signaling molecules to optimize T-cell activation during manufacturing. The resulting ROR1-targeted CAR-T cell product, LYL119, combines these T-cell reprogramming technologies to create potent CAR T cells with durable function (Figure 1A). Healthy donor T cells were manufactured with the Epi-R protocol, activated with a conventional T-cell activation reagent or Stim-R technology, and transduced with a tri-cistronic lentiviral vector encoding a ROR1 CAR, c-Jun, and truncated EGFR. The *NR4A3* gene was disrupted using CRISPR/Cas9 ribonucleoprotein delivery via electroporation. We first evaluated combining NR4A3 KO and c-Jun overexpression in the Epi-R protocol in ROR1 CAR T cells. NR4A3 KO + c-Jun ROR1 CAR T cells consistently demonstrated significant additive benefit with superior cytotoxic activity, prolonged cytokine production, and reduced surface expression of inhibitory receptors after repetitive *in vitro* antigen stimulation, suggesting a mechanism of resistance to exhaustion-induced dysfunction. In the H1975 *in vivo* model, NR4A3 KO + c-Jun CAR T cells demonstrated robust anti-tumor efficacy with activity at a 7-fold reduced CAR T-cell dose (lowest dose, p<0.005, 3 donors) and more than 20-fold greater CAR T-cell expansion in blood compared to control + c-Jun CAR T cells. Even in the difficult-to-treat A549 *in vivo* model, NRA43 KO + c-Jun CAR T cells demonstrated improved tumor control compared to control (p<0.0001). Importantly, NR4A3 KO and c-Jun overexpression did not induce uncontrolled CAR T-cell expansion *in vitro* or *in vivo*. We then evaluated combining Stim-R and Epi-R technologies for ROR1 CAR T production. These cells showed prolonged cytotoxicity and cytokine production *in vitro*, and significantly improved tumor control (p<0.0001), CAR T cell expansion in blood (31-fold, p<0.0001), and overall survival (p<0.0001) in the H1975 *in vivo* model compared to control CAR T cells. Finally, we incorporated NR4A3 KO + c-Jun and Stim-R into the Epi-R protocol and showed that combining our four reprogramming technologies in ROR1 CAR T cells showed additive benefits to prolong *in vitro* cytotoxicity using A549 tumor cells compared to controls (Figure 1B). Together these data suggest that stacking these four technologies can limit exhaustion and has the potential to provide effective and durable ROR1 CAR T-cell functional activity in patients with ROR1⁺ solid tumor malignancies.

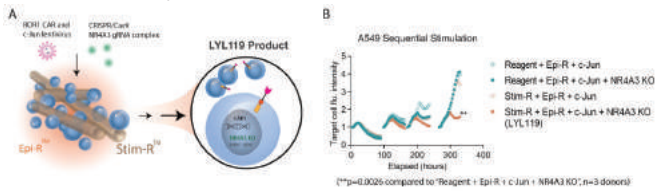

Figure 1. (A) Schematic of LYL119. (B) LYL119 demonstrates prolonged cytotoxicity in vitro (1 of 3 donors shown).

1119 *In Situ* CAR Therapy Using oRNA Lipid Nanoparticles Regresses Tumors *In Vivo*

Amy Becker, Alex Wesselhoeft, Allen Horhata, Akinola Emmanuel, Kevin Kauffman, Sharmistha Kundu, Thomas Lee, David Soto, Akshi Thakkar, Ramya Elangovan, Magnolia Chinn, Renee Wright-Michaud, Meghan Richardson, Chris Wright, Kristen Ott, Jui Dutta-Simmons, Rena Schindler, Trent Stevens, Yessica Wiryawan, Ashley Wong, Ian Langer, Rahul Vungutur, Corey Ciullo, Junghoon Yang, Paisley Haskell, Nelson Chau, Tom Barnes, Robert Mabry

Orna Therapeutics, Cambridge, MA

LNP-mediated delivery of long coding RNA has been clinically validated for vaccines and gene editing. We have been developing a novel, synthetic, circular coding RNA platform (oRNA technology) which exhibits significant improvements in production, expression and formulation compared to mRNAs. Lacking the cap structure of mRNA, our oRNA technology uses a proprietary sequence-based IRES element to initiate protein translation in target cells. At the same time, *ex vivo* generated chimeric antigen receptor (CAR) T cell therapies have had tremendous success in treating hematologic malignancies, yet manufacturing, safety and efficacy challenges remain. We have been combining oRNA technology with novel immunotropic LNPs to address these challenges by creating off-the-shelf yet "autologous" *in situ* CAR (isCAR™) therapies. Our immunotropic LNPs show preferential biodistribution to the spleen with oRNA reporter expression detected in multiple immune

cell subsets including T cells, macrophages and NK cells. Delivery to immune cells is preserved across mice, rats and non-human primates. *In vitro*, expanding human T cells expressing an anti-human CD19 CAR oRNA show potent and sustained cytotoxicity and pro-inflammatory cytokine production compared to controls. To maximize protein expression, we developed the FoRCE (Formulated oRNA Cell-based Evaluation) platform: a robust high-throughput platform that enables parallel arrayed synthesis, purification, lipid nanoparticle (LNP) formulation, and cell-based screening of oRNAs. We applied FoRCE to ~3,000 unique oRNAs containing UTRs extracted from viral genomes and discovered hundreds of IRESs that drive translation from synthetic oRNA in primary human cells across diverse tissues. Select IRESs from this screen drove high levels of CAR expression and cytotoxicity in primary human T cells that were significantly elevated compared to modified mRNA and earlier IRESs. Optimizing the IRES and coding sequences translated into a 20-fold increase in efficacy in mice treated with the corresponding LNP-oRNAs in a human PBMC-engrafted NALM6 tumor-bearing mouse model. The optimized LNP-oCAR enabled weekly dosing at clinically relevant dose levels producing well-tolerated, robust and reproducible efficacy across multiple PBMC donors. Tumor regression was dose-dependent. oRNA-enabled isCAR therapies promise a transient, re-dosable and scalable immune cell therapy without requiring immunodepletion for the treatment of cancer.

1120 Lack of the Classical Complement Pathway in C1q-Deficient Mice Results in Reduced Humoral Responses but Enhanced Cytokine Induction after AAV Dosing

Robert J. Jimenez[1], Blake A. Williams[1], Michael R. Emami[1], Philip K. Farahat[2], Philip Felgner[2], Armando Villalta[2], Melissa J. Spencer[1]

[1]University of California Los Angeles, Los Angeles, CA,[2]University of California Irvine, Irvine, CA

High doses of systemically delivered AAV have been associated with serious adverse events like thrombotic microangiopathy (TMA) and atypical hemolytic uremic syndrome (aHUS) in clinical trials. Both syndromes are associated with excessive activation of the complement system. Subsequent studies demonstrated that AAV-induced complement activation is antibody-dependent, implicating the classical pathway (Smith et al., 2022). Because complement is one of the first elements of immunity to recognize AAV, we sought to understand better how activation of classical complement and generation of its split products enhances downstream immune responses. To improve our understanding of how classical complement influences immune responses to high-dose AAV, we dosed C1qa knockout mice (Jackson Labs, *B6(Cg)-C1qatm1d*(EUCOMM)Wtsi/TennJ). C1q is the first complement component to recognize antibodies on opsonized antigens and, therefore the first complement protein to recognize AAV-antibody immune complexes. We dosed C1q homozygous knockout mice and *C57Bl6/J* wildtype mice with AAV9-CMV-GFP (1.2E14vg/kg) with an initial dose to prime adaptive immunity followed by a second dose of AAV9-CMV-mCherry four weeks later. Blood was collected before dosing and then 5 hours and 2 weeks after each dose. The humoral response to AAV dosing was tested on high-content protein microarray chips and showed that while both WT and *C1q-/-* mice induced anti-capsid IgM responses, only WT mice had a linear increase in anti-AAV-IgG while the induction of anti-AAV IgG was blunted in *C1q -/-* mice. These data suggest that *C1q-/-* mice show a defect in IgM to IgG class switching. Previously, only the complement split product C3d was associated with the process of switching IgM to IgG classes, which cannot be directly induced by classical complement activation. In spite of the blunted humoral response *C1q-/-* mice showed a much stronger induction of monocyte-derived chemokines than WT mice. Chemokines such as CXCL10 and MCP1 were induced five hours after the second AAV dose in both genotypes of mice. This enhanced chemokine induction after the second administration of AAV was observed in cohorts of mice dosed at both four-week and two-week intervals. The aim of our future research is to understand the mechanisms by which classical complement influences switching between immunoglobulin classes and why induction of monocyte-derived chemokines are enhanced in the absence of C1q.

1121 TARGET-AAV: Tissue-Specific Alternative Splicing to Regulate Globally Expressed Therapeutics

Marina M. Scotti, Hailey R. Olafson, Carmen M. Valero, Leanne M. Adams, Derek R. Muscato, Xiaoxiao Wang, Eric T. Wang

Molecular Genetics & Microbiology, University of Florida, Gainesville, FL

Systemic delivery of AAV to replace defective genes has proven to be an effective therapeutic approach. However, the large vector doses required for therapeutic efficacy can place extreme burdens on off-target tissues such as the liver. In some cases, the undesired transduction and subsequent transgene expression in these tissues can have devastating toxic effects in lieu of the desired therapeutic outcome. Improvements in capsid tropism and promoter sequences have alleviated some off-target concerns, but transgene expression is still largely un-regulated. Further, tissue-specific cargo regulation may be required to prevent toxicity in diseases where dissimilar gene expression levels are necessary for therapeutic efficacy, such as muscular dystrophies where heart and skeletal muscle are often both affected. Gene expression regulation by RNA splicing has been well studied over many decades. RNA splicing provides an added regulatory element that is tunable and well-regulated. Here, we describe the exploitation and application of RNA splicing mechanisms to regulate gene therapy expression in a tissue-specific manner. Others have demonstrated the possibility of RNA-mediated expression control in different cell types of the brain or through the use of small molecule splicing modulation. In a parallel approach, our lab has developed a high throughput alternative exon identification pipeline coupled with *in vivo* screening and selection of alternative exon libraries to identify transgene expression with tissue-specific expression patterns and behaviors. Using **t**issue-specific **a**lternative splicing to **r**egulate **g**lobally **e**xpressed **t**herapeutic AAV (TARGET-AAV), we have identified alternative exons that, when expressed in combination with AAV transgene delivery, can enhance tissue-specific expression levels and patterns.

1122 Therapeutic Gene Editing of CFTR to Treat Cystic Fibrosis, Using Nanoparticle Formulations for the Delivery of CRISPR/Cas9

Miriam L. Greenwood[1], Stephen L. Hart[2]

[1]Genetics and Genomic Medicine, UCL Institute of Child Health, London, United Kingdom,[2]UCL Great Ormond Street Institute of Child Health, London, United Kingdom

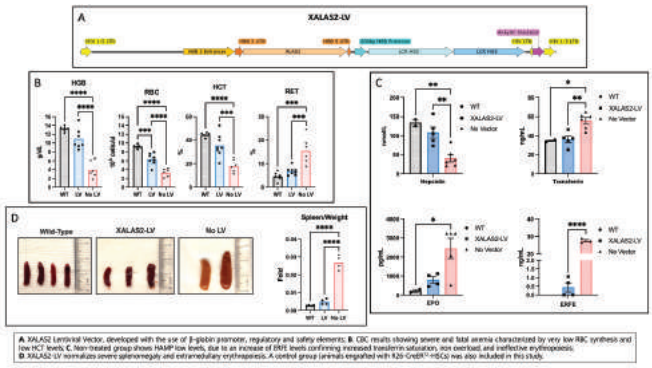
Background:Cystic fibrosis (CF) is an autosomal recessive disease caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene. The dysfunctional CFTR protein leads to thickened mucus, bacterial infections, and reduced lung function. Modulators are effective treatments for many CFTR genotypes, but ~20% of patients remain untreatable. Aims:The aim was to develop a nanoparticle formulation to deliver CRISPR/Cas9 to therapeutically edit *CFTR* mutations *in vitro*, and to investigate the effect of cellular obstacles to transfection including endocytic uptake, endosomal escape and nuclear entry on transfection efficiency. As CF involves inflammation of the lung, a further aim was to determine whether delivery exacerbates inflammation. Methods:Plasmid DNA (pDNA) was packaged into receptor-targeted nanocomplexes (RTNs), comprising liposome and a targeting peptide. 16HBE14o- (16HBE) and BMI-1 transduced CFBE F508del cells were transfected with RTNs, and IL-6 protein secretion measured by ELISA as a marker of inflammation. Nuclear uptake and gene expression were evaluated by confocal microscopy, flow cytometry and luciferase assays. Endosomal escape was assessed by adding chloroquine to the transfection. Results:The optimal RTN formulation for transfecting both cell types comprised a liposomal formulation of ditetradecyl trimethyl ammonium propane (DTDTMA), dioleoyl L-α phosphatidyl ethanolamine (DOPE) at a 1:1 molar ratio, combined with a peptide, K_{16}-GA-CSERSMNFCG. Transfection efficiency with GFP pDNA was 21.7% in 16HBE cells and 37.1% in CFBE cells, and the uptake efficiency of Cy5-labelled pDNA was 62.4% and 99.1% respectively. Chloroquine, an enhancer of endosomal escape, reduced RTN transfection efficiency in 16HBE cells. The microscopy showed that many RTNs were perinuclear 48 hours post-transfection in 16HBE cells. mRNA transfection efficiency was significantly higher than pDNA in CFBE cells but not in 16HBE cells. RTN transfection did not significantly increase IL-6 levels, a marker of inflammation, but dexamethasone reduced IL-6 levels in 16HBE cells. Conclusion:Taken together, this work suggests that the major obstacles to transfection were cellular and nuclear uptake in 16HBE cells, and nuclear import, transcription, nuclear export and/or translation in CFBE cells. There was no evidence of an inflammatory response to RTN transfection. Further steps must be taken to develop this gene editing approach before translation *in vivo*.

1123 An Erythroid-Specific Lentiviral Vector Improves Anemia and Iron Metabolism in a New Model of Alas2 Knock-Out X-Linked Sideroblastic Anemia (XLSA)

Carlo Castruccio Castracani, Amaliris Guerra, Laura Breda, Stefano Rivella

Children's Hospital of Philadelphia, Philadelphia, PA

X-linked sideroblastic anemia (XLSA) is the most common form of congenital sideroblastic anemia caused by a germline mutation in the erythroid-specific 5-aminolevulinate synthase (ALAS2) gene. Patients with XLSA are predominantly hemizygous males who exhibit hypochromic microcytic anemia accompanied by systemic iron overload. *Ex-vivo* hematopoietic stem cell (HSC) gene therapy using a lentiviral vector (LV) represents a potential therapeutic option, improving patients' conditions by supplying a functional copy of the ALAS2 cDNA. To control the expression of ALAS2 cDNA in an erythroid fashion, we generated a lentiviral vector expressing human ALAS2 under the control of the human β-globin promoter and elements of the locus control region (LCR). We also included an insulator in the 3' self-inactivating long terminal repeat (SIN-LTR) to enhance safety (Fig.1A). Constitutive knock-out mice of ALAS2 are not viable at birth. Hence, we generated a conditional KO flanking a critical region of the *Alas2* mouse gene with LoxP sites. Untransduced or transduced R26-CreER^{T2}-ALAS2$^{fl/Y}$ Lin- selected cells were then transplanted into lethally irradiated recipients. Eight weeks post engraftment, the *Alas2* gene was deleted through the expression of Cre, initiated by the administration of tamoxifen. Mice treated with the LV and controls (*Alas2*-KO animals) showed significant CBC differences. While the hemoglobin and RBC levels were improved or corrected in the LV-treated group, the non-treated group showed fatal anemia (Fig.1B), with low RBC levels and hematocrit (HCT). Accordingly, the untreated group has increased erythropoietin levels and reticulocyte counts because of ineffective erythropoiesis and severe anemia (Fig.1B-1C). The ineffective erythropoiesis was characterized by extra-medullary erythropoiesis and severe splenomegaly, while XALAS2-LV almost completely normalized these parameters in treated mice (Fig.1D).In non-treated animals, the resulting anemia was also accompanied by increased ERFE, the erythroid regulator of hepcidin, and decreased HAMP levels. As expected, low HAMP levels were associated with increased serum iron and transferrin saturation levels, in line with increased iron absorption, iron overload (Fig. 1C), and ineffective erythropoiesis. These parameters were improved or normalized in the XALAS2-LV-treated group.These data show that the fatal anemia in *Alas2* KO animals can be improved or corrected by XALAS2-LV. Notably, animals rescued by XALAS2-LV showed vector copy numbers (VCN) in the range of 0.5-1.4, indicating that a small number of integrations were sufficient to rescue *Alas2*-KO animals. As XLSA patients still exhibit hypomorphic or residual expression of the ALAS2 gene (as the complete absence is incompatible with survival), we hypothesize that minimal gene transfer or mini-transplants with HSCs treated with XALAS2-LV could be curative in this disease.



1124 An Evolved AAV Variant Enables Efficient Genetic Engineering of Murine T Cells and the Modeling of *Trac*-CAR-T Cells in Immunocompetent Tumor Models

William A. Nyberg[1], Jonathan Ark[2], Angela To[1], Sylvanie Clouden[3], Gabriella Reeder[1], Joseph J. Muldoon[4], Jing-Yi Chung[1], William Xie[1], Vincent Allain[1], Zachary Steinhart[4], Christopher Chang[1], Alexis Talbot[1], Alan Rosales[3], Sandy Kim[5], Patrick Havlik[3], Harold Pimentel[5], Aravind Asokan[3], Justin Eyquem[4]

[1]Medicine, UCSF, San Francisco, CA,[2]Agent Capital, Cambridge, MA,[3]Duke University, Durham, NC,[4]UCSF, San Francisco, CA,[5]UCLA, Los Angeles, CA

Precise targeting of large transgenes to T cells using homology-directed repair (HDR) has been transformative for adoptive cell therapies and T cell biology. Delivery of HDR templates via adeno-associated virus (AAV) has greatly improved knockin efficiencies, but the tropism of current AAV serotypes largely restricts their use to human T cells employed in immunodeficient xenograft mouse models. To enable targeted knockins in murine T cells, we evolved Ark313, a synthetic AAV that exhibits very high transduction efficiency in murine T cells. To identify the essential host factors for Ark313 transduction, we performed a genome-wide knockout screen and identified the MHC-I molecule QA2 as an essential factor for Ark313 infection. We demonstrate that Ark313 can be used for nucleofection-free DNA delivery, CRISPR-Cas9-mediated knockouts, and targeted integration of large transgenes with up to 75% knockin efficiency. Ark313 enables preclinical modeling of *Trac*-targeted CAR-T and transgenic TCR-T cells in immunocompetent models. We compared murine *Trac*-CAR-T cells and gRV CAR-T cells in a solid lung tumor model and *Trac*-targeted CAR T cells displayed increased tumor infiltration and significant improvement in survival compared to gRV CAR-T cells. Next, we assessed Ark313 for in vivo engineering of T cells. We first injected a single dose of Ark313 expressing Cre recombinase in Ai9 fluorescent reporter mice and achieved permanent genetic changes in >20% of splenocyte T cells in vivo. Additionally, Ark313 tropism for T cells was associated significant liver de-targeting relative to parental AAV6. We then injected Ark313 expressing a *Trac*-targeting sgRNA in Cas9 expressing mice and achieved TCR KO in >10% T cells in vivo. These results demonstrate the ability to perform CRISPR based gene editing in T cells in vivo using AAV delivery. These new advancements open avenues for functional genomics in vivo and experimental modeling of gene edited T cells in immunocompetent settings.

1125 Increasing Erythropoietic Output from Genome-Edited Hematopoietic Stem and Progenitor Cells Using a Truncated EPO Receptor

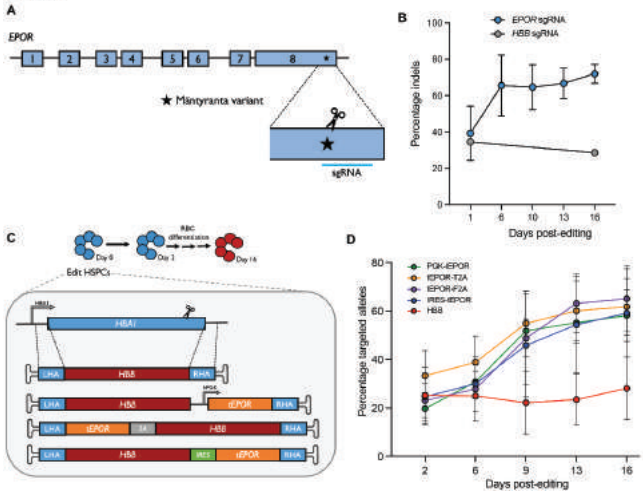
Sofia E. Luna[1], Joab Camarena[1], Jessica P. Hampton[1], Kiran R. Majeti[1], Carsten T. Charlesworth[1], Eric Soupene[2], Vivien Sheehan[3], Kyle Cromer[4], Matthew H. Porteus[1]

[1]Stanford University, Stanford, CA,[2]University of California, San Francisco, Oakland, CA,[3]Emory University, Atlanta, GA,[4]University of California, San Francisco, San Francisco, CA

Genome-edited hematopoietic stem and progenitor cells (HSPCs) yield genome-corrected cells of all lineages, yet the only cell type of clinical relevance to the hemoglobinopathies is the red blood cell (RBC). With this in mind, we aimed to develop a novel genome editing strategy to enrich edited HSPCs within the erythroid lineage. This could allow low HSPC chimerism in the bone marrow to yield high levels of RBC chimerism in the bloodstream, thereby amplifying the efficacy of hemoglobinopathy treatments in the clinic. From human clinical genetics we know truncations in the erythropoietin receptor (EPOR) cause benign erythrocytosis, yielding non-pathogenic hyper-production of RBCs. This variant was first identified in a cohort that included a Finnish Olympic cross-country skier and does not cause any clinical pathology besides an elevated hemoglobin. We hypothesized we could recapitulate this natural variant using CRISPR/Cas9 genome editing to create insertions/deletions (indels) at the *EPOR* locus near the site of the Olympic skier's mutation (Mäntyranta variant) (Figure 1A). We demonstrated increased erythropoietic output from cells containing truncating mutations in *EPOR*, shown by an increase in indel formation throughout erythroid differentiation using an *EPOR* single guide RNA (sgRNA) versus no increase in a control sgRNA targeting *HBB* (Figure 1B). Because not all indels created caused truncations in *EPOR*, we next explored whether we could amplify this proliferative effect by inserting a truncated EPOR (*tEPOR*) cDNA in the endogenous locus and found this strategy also enriched for cells with the truncation as they developed during erythroid differentiation. Next, we investigated whether the *tEPOR* cDNA could be targeted to the *CCR5* safe harbor locus under ubiquitous expression or to the *HBA1* RBC-specific safe harbor site imparting high levels of erythroid specific expression. We demonstrated that integration of the *tEPOR* cDNA at both loci produced strong enrichment of edited alleles in an EPO-dependent manner when put through erythroid differentiation. Lastly, we sought to pair the *tEPOR* cDNA with a clinical edit for β-thalassemia to boost production of disease-corrected RBCs. We showed that through use of bicistronic cassettes (Figure 1C) we were able to drive a >2-fold enrichment of edited alleles over the course of differentiation (Figure 1D). Additionally, we were able to pair the *tEPOR* cDNA and clinical edit for β-thalassemia through multiplexed gene editing at *EPOR* and *HBA1*, respectively, and again demonstrated enrichment of edited alleles. Ultimately, we believe this work has the potential to amplify the efficacy of gene and cell therapies for blood disorders currently in the

clinic, including both allogeneic and autologous HSPC transplantation. Further, as low chimerism in the bone marrow could produce high levels of peripheral RBCs using our strategy, it has the potential to reduce or eliminate the high-morbidity myeloablation regimens currently required for functional cure of blood disorders. This work, in effect, has the potential to improve the safety and accessibility to currently available treatments for the millions of patients affected by the hemoglobinopathies worldwide.

Figure 1



1126 3D Printed Hydrogel Scaffolds Generated Using Continuous Liquid Interface Production for the Delivery of Neural Stem Cells to Treat Glioblastoma

Lauren Kass, Cathleen DeVane, Addis Tessema, Julia Logan, Jillian Perry, Shawn Hingtgen

University of North Carolina Chapel Hill, Chapel Hill, NC

Background: Neural stem cell (NSC) therapy is a promising new platform for treating glioblastoma (GBM), an aggressive and deadly malignant brain tumor associated with a median survival of only 12-15 months. However, NSCs implanted directly into the GBM resection cavity in mice are cleared from the implant site within 3-5 days, leading to insignificant improvements in overall efficacy. We hypothesized that improving NSC persistence via biomaterial encapsulation in the GBM cavity would lead to better therapeutic efficacy; however, NSC migration from the material must be maintained. To satisfy these conditions, we utilized continuous liquid interface production (CLIP) to 3D-print biocompatible hydrogel scaffolds, on which NSCs would be seeded. We hypothesize that the scaffold architecture could act as a physical barrier to NSC clearance, permitting enhanced *in vivo* NSC viability without compromising cell migration. Methods: CLIP was used to generate a 3D gelatin methacryloyl (GelMA)- and poly(ethylene glycol) diacrylate (PEGDA) hydrogel scaffold, cylindrical in shape with a latticed design (Fig. 1). NSCs were seeded onto the external scaffold surfaces via a combined static and centrifugal seeding method. NSC viability on the scaffold was quantified with BLI imaging, and SEM imaging was used to evaluate cell confluency, attachment, and morphology of the NSCs on the scaffold over time. Fluorescence imaging was used to assess cell migration patterns of NSCs to GBM tumors from CLIP scaffolds. *In vivo* persistence was studied by implanting NSC-loaded CLIP scaffolds into mock resection cavities in athymic nude mice, after which NSCs were tracked via BLI. Results: NSCs seeded onto the biocompatible CLIP scaffolds, following 14 days in culture the NSCs proliferated to a density over 30-fold higher than the initial seeding density. SEM images depicted changes to NSC morphology on the scaffolds over time, in which the cells initially took on a spherical shape that changed to a flattened morphology as they attached firmly to the scaffold material. In vitro migrations studies indicate that NSCs cultured on CLIP scaffolds could leave the scaffold and migrate to GBM cells. *In vivo* persistence studies showed that NSCs on CLIP scaffolds implanted in the brains of healthy mice, continued to proliferate to 20% higher than the seeded dose by day 6, then exhibited a slow decline in persistence until day 15. Contrastingly, NSCs injected into the resection cavity in PBS showed an immediate and sustained decrease in persistence, and by day 6 over 70% of the initial NSC signal was lost. Future Directions: In the future, we will evaluate the ability for NSCs on CLIP scaffolds to produce a more robust therapeutic effect in our model of GBM resection in mice.

Pyruvate kinase deficiency (PKD) is an autosomal recessive disorder caused by mutations in PKLR gene. PKD-erythrocytes suffer from energy imbalanced caused by reduction of erythroid pyruvate kinase (RPK) activity. PKD is associated with hemolysis, reticulocytosis, splenomegaly and iron overload, and may be life-threatening. We developed a knock-in gene editing strategy by combining ribonucleoprotein electroporation and adeno-associated viral vector (rAAV6) donor delivery, getting relevant editing in hematopoietic stem and progenitor cells (HSPCs) from mobilized peripheral blood (mPB). Since HDR gene editing is a homogeneous modification of the genome, clonal and cell tracking studies of edited cells cannot be performed as it can with lentiviral marking. Thus, we developed a donor DNA barcode AAV6 library to allow the clonal dynamics of genome edited cells to be determined and used the assay to assess potential improvements in genome editing efficacy. Here we describe how additional modifications in gene editing protocol increase the targeted integration frequency to~70%. First, changes in the cell concentration in the procedure increase the editing 2-fold. Second, we tested nine different compounds. Two of them, one involved in the inhibition of DNA-PK pathway which can act as an inhibitor of NHEJ pathway and a specific inhibitor of HDAC class I/II, render good improvements. With the use of the DNA-PK pathway inhibitor, we increased 1.5-fold PKLR gene editing in mPB cells. There were no differences in the number of individual clones *in vitro*. When the inhibitor of the HDAC class I/II was used, we did not observe any increase in targeted integration, but when we combined both, targeted integration increases 1.8-fold with respect to untreated cells. The combination of both compounds maintains the numbers of individual clones *in vitro.* There were no changes in viability, *in vitro* expansion capabilities or total colony forming ability of edited $CD34^+$ cells in any of the combinations. We are currently assessing the number of targeted integrated HSPC clones engrafted in immunodeficient mice to evaluate their effect in the most primitive HSPC compartment. To sum up, we were able to enhance *PKLR* gene targeted integration and maintain the clonal repertoire *in vitro* by adding these enhancers. These data would facilitate the clinical use of gene targeted integration therapy for PKD.

1128 Targeting the Hepatitis B cccDNA with the hfCas12Max Nuclease to Eliminate Hepatitis B Virus *In Vitro* and *In Vivo*

Yinghui Wei[1], Weiya Bai[1], Haosha Tang[1], Zikang Wang[1], Ningxin Ren[1], Yan Wang[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Hepatitis B virus (HBV) is a hepatotropic, non-cytopathic DNA virus that generates a covalently-closed-circular-DNA (cccDNA) intermediate in the nucleus of infected cells as well as integrated sequences that act as transcription templates for viral proteins. Antiviral therapies with nucleoside analogues inhibit replication of HBV DNA in capsids present in the cytoplasm of infected cells, but do not reduce or destroy nuclear cccDNA. Here, we describe a potential curative approach using a proprietary highly specific engineered Cas12i nuclease (hfCas12Max) targeting the hepatitis B virus (HBV) genome. **Methods**: Effective guide RNAs (gRNAs) were firstly selected and screened in PiggyBac (PB)-HBV-HEK293 system. In addition, functional gRNAs screen was performed in HBV-integrated cell lines and HBV-infected primary human hepatocytes (PHHs). To evaluate the hfCas12Max nuclease *in vivo*, we developed episomal adeno-associated virus (AAV) mouse model containing 1.3-fold HBV genome serving as a surrogate for cccDNA. Clinically relevant delivery was achieved through systemic administration of lipid nanoparticles (LNP) containing hfCas12Max mRNA and gRNAs. **Results**: Lead gRNAs targeting hepatitis B surface antigen (HBsAg) and other related genes were identified in HBV-integrated hepatic cell lines. Through the LNP delivery, hfCas12Max targeting resulted in a significant reduction of cccDNA, HBV-DNA, and HBsAg in HBV-infected PHHs (Fig. 1A-C). In the AAV-HBV mouse model, we observed sustained reductions in HBsAg expression (~2log) and serum HBV DNA (~3log) after LNP-mediated systemic delivery of the CRISPR- hfCas12Max system (Fig. 2A-B). **Conclusions**: Our data suggest that the CRISPR- hfCas12Max system could disrupt the HBV expressing templates both *in vitro* and *in vivo*, indicating its potential in eradicating cccDNA toward a potential cure for HBV.

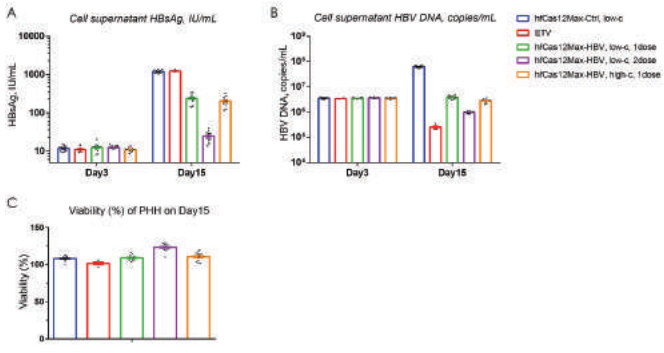

Figure 1. LNP-mediated delivery of hfCas12Max mRNA and gRNAs reduces HBV viral parameters in primary human hepatocytes (PHH). A, B) HBV replication assessed by HBsAg ELISA and HBV DNA qPCR in PHH supernatant. Cas12i-targeting leads to the efficient reduction of HBsAg (A) and HBV DNA (B). C) The viability of PHH cells in each group was unaffected on day 15.

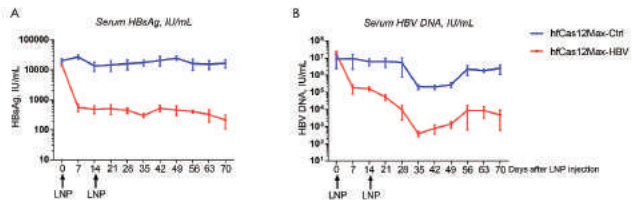

Figure 2. LNP-mediated delivery of hfCas12Max mRNA and gRNAs leads to sustained reduction of viral markers in AAV-HBV mouse model. A, B) The AAV-HBV mouse model was used in the *in vivo* pilot study. 4 weeks after hydrodynamic injection with AAV8-1.3-fold HBV genome, mice received two doses (2x) of the hfCas12Max-targeting reagents (mRNA & gRNA formulated into LNP). hfCas12Max nuclease treatment resulted in sustained reductions in HBsAg expression (~2log) (A) and HBV DNA (~3log) (B) in serum.

1129 Quality Control Pipeline for AAV Production

Ana Orlowsky[1], Irina Kramerova[1], Robert Jimenez[1], Jesus Perez[1], Michael R. Emami[1], Courtney Young[2], Melissa J. Spencer[1]

[1]UCLA, Los Angeles, CA,[2]MyoGene Bio, San Diego, CA

Recombinant Adeno Associated Vectors (AAV) are used to deliver therapeutic genes to target cells throughout the body for gene therapy applications. To ensure consistency and purity of each batch of vector, quality control in AAV packaging and purification is crucial. Several factors can affect the therapeutic efficacy of AAV vectors due to a lack of quality control. Differences in quality can be due to process and product-related contamination, packaging efficiency and rearrangements or truncations of the packaged DNA. Our lab is developing a pipeline to establish quality control for all AAV preparations made in-house or obtained from companies, to improve the consistency and reliability of our AAV-based studies. Controls are included to enable the assessment of empty/full ratios of AAV preps. Standards purchased from Virovek allowed us to generate a standard curve of the empty/full ratios that is compared to our samples. Our evaluation of an unknown sample begins by assessing diluted crude lysates after packaging using qPCR to determine the integrity of the packaged product and to give an estimate of the titer before purification. After purification, the final genome titer is determined by ddPCR. The protein titer is determined by BCA and ELISA to quantify the concentration of capsid proteins then evaluated by Coomassie-stained polyacrylamide gels to confirm the protein purity and VP ratio of the sample. The packaged DNA is evaluated by alkaline gels to confirm the size of the packaged material and to provide a crude estimate of purity. If there are unusual bands then we perform long read sequencing and/or perform qPCR for the most common DNA contaminants. Capillary electrophoresis using the Jess system (ProteinSimple, San Jose, CA) is used to assess both VP proteins and dsDNA in tandem. The westerns are performed using a primary antibody specific to a common region in VP1/VP2/VP3 and another antibody to dsDNA. Good detection of both transgene and VP protein are achieved using minute amounts of our AAV samples. For each assay, we load based on total protein concentration. We have been troubleshooting the optimal approach to preparing AAV preps for each analysis of both the capsid and transgene for analysis. Analysis requires either a detergent or boiling to separate the AAV capsid proteins and to release the genome. Ultimately, we aim to identify the optimal approach to analyze the empty/full ratio and purity for each AAV preparation to determine which assays predict the efficacy of AAV for neuromuscular applications.

1130 Emerging Maxims for the Ethics of Preventive Human Gene Editing

R. Jean Cadigan, Margaret Waltz, John Conley, Gail Henderson, Doug MacKay, Rami Major, Rebecca Walker, Eric Juengst

University of North Carolina, Chapel Hill, Chapel Hill, NC

Introduction: Over the past decade, the field of gene editing research has exploded thanks primarily to CRISPR technologies. As the biomedical implications of this research have become apparent, recent years have seen a global wave of efforts to develop anticipatory guidance for various sorts of human gene editing applications. But for the most part, they do not address research aimed at somatic cell human gene editing for the purpose of prevention, or strengthening human resilience in the face of genetic, environmental, and infectious disease threats. Since, in principle, this prospect triggers human enhancement concerns, those involved in this research have been challenged to come up with distinctive safeguards and criteria, "moral maxims," to justify their efforts. In this presentation, we report on three of these maxims and the questions they raise for further bioethical analysis and public discussion. Methods: We identified these maxims in two ways. First, we conducted interviews with 92 gene editing scientists and policy makers about their views on different uses of gene editing and potential ways gene editing research should be regulated. Interviews were recorded and transcribed verbatim. Second, we analyzed the ongoing global policy discussions on human gene editing research regarding preventive interventions that raise enhancement concerns, including reports from the World Health Organization, US National Academies of Sciences, Engineering and Medicine, and the European Commission. Results: We identified three sets of governance prescriptions in the efforts by scientists, science policy makers, and bioethics scholars to address the challenge that preventive uses of gene editing pose for the traditional wariness of genetic enhancement: the "privileging prevalence" maxim; the "privileging transience" maxim, and the "privileging public engagement" maxim. The privileging prevalence maxim advocates that only common functional variants (vs. rare variants, variants from non-human animals, and artificial variants) should be used to improve disease resistance, even if the alternatives could be more effective in achieving preventive goals. The privileging transience maxim encourages that any preventive human gene editing interventions should be either reversible or temporary. Finally, the privileging public engagement maxim prescribes that any policy decisions about the interface between prevention and enhancement should depend on active public participation and "broad societal consensus." Conclusions: We will conclude the presentation with a discussion of the ethical considerations and questions raised by these maxims. For instance, given the diversity of human variation that we otherwise seek to respect and protect, why should the most prevalent traits be privileged? What rules should govern the "dialing down" of preventive enhancements in application settings? And how do logistics, jurisdiction, and authority influence public engagement? If these maxims are used, they have the potential to influence policy and practice, and therefore deserve careful scrutiny.

1131 ABO-503, a Novel Gene Therapy for Treatment of X-Linked Retinoschisis

Joseph Fogerty[1], Paul T. Wille[1], Linas Padegimas[2], Brian M. Kevany[1]

[1]Abeona Therapeutics, Cleveland, OH,[2]Forge Biologics, Grove City, OH

X-linked retinoschisis (XLRS) is a rare, monogenic disease that results in severe visual impairment. The disease is caused by mutations in the *RS1* gene, which is normally secreted by retinal photoreceptors and bipolar neurons and functions to mediate cell-cell adhesion. Affected individuals develop cavities between the layers of the retina where these interactions are disrupted, leading to discontinuity in the retinal circuitry and the irreversible loss of photoreceptor cells. The current standard of care for XLRS patients is limited to palliative measures, but because the genetics of the disease are well understood, early intervention via gene therapy has significant potential to reverse or stabilize disease progression at early stages and prevent vision loss and the occurrence of more severe disease complications. ABO-503 is a novel AAV-vectored gene therapy that delivers wild-type *RS1* to photoreceptors using the AIM™ capsid AAV204. In this study, we examined RS1 expression specifically in photoreceptor cells via the *GRK1* promoter following subretinal administration in *Rs1* mutant mice. Animals were treated at p21 and examined 6 months later. Robust RS1 expression was observed in photoreceptor cells near the injection site as well as in the adjacent inner retina. RS1 expression was associated with an improvement in cone photoreceptor density and an increased thickness of the photoreceptor nuclear layer. In addition, full-field flicker ERG analysis showed a significant improvement in cone photoreceptor function. These experiments demonstrate that ABO-503 effectively rescues RS1 expression in mutant mice and delivers a measurable therapeutic benefit. We previously demonstrated that AAV204, expressing GFP, is superior to natural and other engineered capsids tested using intravitreal and para-retinal routes of administration. Additionally, para-retinal injection resulted in no observable immune response and robust expression in the macula, despite using a log lower dose. To eliminate the possible risk of irreversible damage from subretinal dosing in fragile retinoschisis eyes, further studies will assess delivery of ABO-503 via para-retinal administration in non-human primates to support future clinical development.

1132 Positive and Negative Selection of Anti-HIV-1 Gene-Modified Human Hematopoietic Stem/Progenitor Cells (HSPC) to Improve Engraftment and Efficient HIV-1 Inhibition with a Safety Kill Switch in Humanized BLT Mice

Qi Guo[1,2], Wannisa Khamaikawin[1,2], Jian Zhang[1,2], Keval Parikh[1,2], Alexander Brinkley[1,2], Sarah Schroeder[1,2], Kory Hamane[1,2], Christina Zakarian[1,2], Martin Zakarian[1,2], Dong Sung An[1,2]

[1]School of Nursing, University of California, Los Angeles, Los Angeles, CA,[2]UCLA AIDS Institute, Los Angeles, CA

Anti-HIV-1 HSPC-based gene therapy has great promise for HIV-1 cure. However, it's been difficult to achieve therapeutic levels of engraftment. Thus, a positive selection strategy is highly desirable for enriching the level of anti-HIV-1 gene-engineered cells for more robust HIV-1 inhibition. Additionally, the incorporation of a "kill-switch" to eliminate the genetically engineered anti-HIV-1 immune effector cells in cases of unexpected adverse effects, such as transformation by insertional mutagenesis and cytokine storm, is important for safety. We developed two positive selection strategies to maximize the repopulation of genetically engineered anti-HIV-1 gene-modified HSPC. First, we knocked down hypoxanthine-guanine phosphoribosyltransferase (HPRT) expression using RNA interference that enabled us to effectively enrich anti-HIV-1 gene-modified HSPC using clinically available prodrug 6-thioguanine(6TG) in vivo. Second, we co-expressed truncated non-functional human epidermal growth factor receptor (huEGFRt) cell surface marker for rapid ex vivo sorting of gene-modified HSPC by FDA-approved anti-huEGFR monoclonal antibody Cetuximab. huEGFRt can be also used as a safety elimination strategy for the gene-engineered effector immune cells in case of unexpected adverse effects via cetuximab antibody-dependent cellular cytotoxicity (ADCC). We developed lentiviral vectors that express triple anti-HIV genes (CD4-based CAR, C46, and CCR5 shRNA) and either HPRTshRNA or huEGFRt for the selection strategies. The effectiveness of positive and negative selection and HIV inhibition of anti-HIV gene-modified human HSPC was examined in the humanized BLT (hu-BLT) mouse model. We successfully increased the engraftment of anti-HIV-1 vector transduced human CD34+ HSPC by knocking down HPRT expression and 6TG-mediated positive selection. Vector marking level (~1 vector DNA copies/cell) increased >2-fold over 7 weeks in hu-BLT mice (n=15, $p<0.001$). Viral load was significantly reduced >1-log reduction in 6TG treated mice compared to untreated mice (n=16) up to 4 weeks post-HIV-1 challenge ($p<0.05$). An anti-HIV-1 vector with huEGFRt resulted in >80% transduction in human CD34+ HSPC and transplantation resulted in high anti-HIV-1 vector marking at ~2 vector DNA copies/cell over 9 weeks in hu-BLT mice. The high level vector marking resulted in significant viral load reduction (> 0.76-log reduction $p<0.001$) for 6 weeks post-HIV-1 challenge compared to control non-transduced HSPC transplanted hu-BLT mice. We successfully reduced the huEGFRt expressing anti HIV-1 gene-modified cells by Cetuximab mediated negative selection for 15-fold in peripheral blood, 2-fold in spleen and 4-fold in bone marrow up to 5 weeks in hu-BLT mice. In conclusion, our newly developed positively and negatively selectable anti-HIV vectors have the potential to overcome the limitations of low engraftment of gene-modified HSPC for highly robust HIV-1 inhibition and an improved safety as a safety kill switch in cases of unexpected adverse effects caused by the genetically engineered cells.

1133 Using Design of Experiments to Optimize Microfluidic Transfection Platform for Cas9 RNP and mRNA Delivery in Various Cell Types

Tiffany Dunn, Ailin M. Goff, Ian Sicher, Sewoon Han, Anuya Kamath, Struan Bourke, Ockchul Kim, Melis Keceli, Alla Zamarayeva, Alexeev Alexander, Todd Sulchek, Chih-Wen Ni

CellFE, Alameda, CA

Introduction: Mechanoporation can be used for intracellular delivery in which efficiency, cell health, and simple processing is needed. We have developed a microfluidic consumable designed to deliver gene

modifying payload into human primary cells using mechanoporation. Due to the large microchannel parameter space, thorough optimization for a specific application or cell types can require lengthy development times. We use a statistical approach of multivariate optimization using design of experiments (DoE) and response surface methodology (RSM) to assess the effects of several parameters and simultaneously optimize for maximizing transfection efficiency and cell viability. Using this approach, we can decrease the number of tests and the number of conditions necessary to find an optimal device parameter operating window. To test this approach, we delivered enhanced green fluorescence protein (EGFP) messenger RNA (mRNA) in hematopoietic stem/progenitor cells (HSPCs) as a proof of concept, a cell type with relevance in gene therapy with capabilities of self-renewal and differentiation into myeloid and lymphoid cell types. In addition to this application, we expand this approach to the transfection of either mRNA or Cas9 ribonucleoprotein (RNP) complex into fresh peripheral blood mononuclear cells (PBMCs) and CD3+ T-Cells subpopulations due to the clinical needs for T-cell engineering for cell therapy. **Materials and Methods:** Transfection was achieved by use of our Zephyr instrument to generate pressure-driven flow of cells and cargo through microfluidic consumables. The design of the experiment conducted was generated using JMP software to create a D-Optimal design for a response surface model. Analysis of the resulting data was also completed using JMP to fit a linear model and perform the subsequent stepwise-backward model reduction. A residual maximum likelihood model (REML) was constructed for each response to assess fixed device and instrument parameters. This method also allows us to include random effects, or effects that we would like to make inference about the wider population, rather than only the levels tested in this study. Delivery efficiencies were measured using flow cytometry to detect either the EGFP expression from mRNA, or the knock-out (KO) of T-cell receptor alpha/beta chain (TRAC) from the delivery of targeted Cas9 RNP. **Results and Discussion:** We assessed a list of microchannel design factors with potential to affect transfection efficiency and cell viability of HSPCs. We were able to achieve >80% mRNA delivery while maintaining >80% cell viability. By using DoE methodologies, we were able to quickly assess the importance of several device parameters and explore each factor's two-term interaction effects, as well as quadratic effects. Results of the follow up experiment confirmed model predictions within the 95% confidence interval that was created by the original model. After the success of this experiment for HSPCs, we have since discovered the optimal operating window of each parameter tested to simultaneously optimize both cell viability and transfection efficiency in the PBMC and CD3+ T-cell applications. **Conclusions:** In this study, we established an optimized microfluidic channel design that produced optimal mRNA delivery efficiencies and cell viability. We also expanded these methods to 2 additional cell types and an additional payload. The DoE methodology has simplified design search for complicated parameter space, requiring fewer runs to acquire quality data while assessing for statistical significance. In future studies, we plan to apply these methods to optimize for genetic modifications of HSPCs using CRISPR/Cas 9 RNP. Equal contributors: TD, IS, AK

1134 Optimizing Helper Plasmids by Removing Unnecessary "Junk" DNA Significantly Increases AAV Productivity

Diane Golebiowski, Laura van Lieshout, Stacy Ota, Katrina Costa-Grant, Jin Yin, Tim Kelly

Oxford Biomedica Solutions, Bedford, MA

Production of adeno-associated virus (AAV) vectors using live adenovirus infection has largely been replaced with a plasmid containing the necessary adenovirus genes to facilitate AAV replication for safety and logistical considerations. Helper plasmid (pHelper) contains three adenovirus genes: E2a, E4 and VA RNA. Although there are a number of different pHelper plasmids available, they all minimally contain these three genes, along with various additional sequence structure. These genes can contain larger regions than the promoter and coding sequence due to the nature of the adenovirus genome structure, that could be referred to as "junk" DNA as it pertains to AAV replication. We sought to reduce the size of our pHelper by removing regions of the adenoviral genes that were not essential to their function. Five plasmids containing various deletions were generated, with deletions ranging from 2-3.5 kb. All five of these smaller Helper plasmids increased vector genome (VG) productivity to various extents across multiple genomes. Capsid production also increases proportionally to VGs using the smaller pHelpers. We have achieved statistically significant increases in VG production through the removal of "junk" regions of our current Helper plasmid. Our working hypothesis is that the removal of non-coding regions of the adenoviral genes is altering the expression of E2a and E4 proteins, which enables higher capsid expression and in turn more VGs are packaged into the available capsids.

1135 False Positive HIV Testing Results and Recommendation for HIV Testing in Patients Treated with Lentiviral Based Chimeric Antigen Receptor T Cells

Emanuela Marcucci, Marissa M. Del Real, Sanjeet Dadwal, Bernard Tegtmeier, Jamie Wagner, Lihua E. Budde

City of Hope, Duarte, CA

Since the Food and Drug Administration first approved CD19-targeted chimeric antigen receptor (CAR) T cell therapy for B cell cancers in 2017, the number of products and indications have expanded, leading to an increasing number of cancer patients receiving CAR T cell therapy. To generate CAR T cells, cells isolated from patients are genetically engineered to express a CAR gene, which is often incorporated into a lentiviral vector. Most of the CAR T cell products are manufactured using a lentiviral vector with a modified HIV backbone and, thus, contains partial sequences from the HIV genome. Following CAR T cell infusion, patients treated with CAR T cells that contain the components of the HIV genome can have false positive HIV test results, which can cause unnecessary stress to the patient, families and caregivers. There are several approved clinical HIV diagnostic tests that use different technologies to detect HIV viral proteins or genetic sequences. Here we presented 10 patients as case studies for false HIV positive tests while receiving COH-19 CD19 CAR T therapy. Each patient was determined to be HIV negative prior to CAR T cell infusion and the

false positives were detected at various timepoints after CAR T infusion (6 months to 4 years). We then investigated the use of 3 different tests using PCR to detect HIV viral sequences including the long terminal repeat (LTR), group antigens (gag) and reverse transcriptase (pol). We collected peripheral blood from patients receiving commercial CAR T cell therapy, including tisagenlecleucel, lisocabtagene maraleucel, or axicabtagene ciloleucel which was used as negative control. We tested each of the post infusion patient samples for HIV using 1) COBAS AmpliPrep/COBAS TaqMan Quantitative HIV-1 test, 2) Aptima HIV-1 RNA Qualitative Assay, and 3) Abbott real time HIV test. We found that the COBAS TaqMan Quantitative HIV-1 test consistently yielded positive results in some patients post CAR T cell treatment. The COBAS TaqMan Quantitative test amplifies both LTR and gag sequences of the HIV viral genome, which are the parts of the sequence that are present in CAR T cells. As a result, this test may cause false positives in patients who have received CAR T cells. Neither of the other 2 tests resulted in positive results in samples collected from CAR T patients. Thus, when conducting HIV testing in patients with prior lentiviral based CAR T cell therapy, we recommend for patients with normal B cell counts to perform a HIV antigen/antibody combo test. For patients with B cell aplasia/hypogammaglobulinemia that an HIV PCR test is performed along with CAR specific persistent measurement such as quantitative WPRE detection. The COBAS TaqMan Quantitative test should not be used for HIV testing in patients receiving lentiviral based CAR T therapy.

1136 SNK-01 Autologous Enhanced Natural Killer Cells and an Immune Checkpoint Inhibitor Control Tumor Growth in Rare Chemotherapy-Resistant Advanced Soft Tissue Sarcomas

Nadezhda Omelchenko[1], Neal Chawla[2], Victoria Chua-Alcala[2], Don A. Brigham[2], Sant Chawla[1], Paul Song[3], Paul Chang[4], Erlinda M. Gordon[5,6]

[1]Medical Oncology, Sarcoma Oncology Center, Santa Monica, CA,[2]Medical Oncology, Cancer Center of Southern California/Sarcoma Oncology Research Center, Santa Monica, CA,[3]Medical Oncology, NKGen Biotech Inc., Santa Ana, CA,[4]Medical Oncology, NKGen Biotech, Inc., Santa ana, CA,[5]Cancer Center of Southern California/Sarcoma Oncology Research Center, Santa Monica, CA,[6]Medical Oncology, Aveni Foundation, Santa Monica, CA

Background and Rationale: Advanced or metastatic sarcoma is associated with an invariably fatal outcome. SNK01 is a first-in-kind, autologous non-genetically modified natural killer cell therapy with highly enhanced cytotoxicity and over 90% activating receptor expression which can be consistently produced from chemotherapy-treated patients. **Objective:** To report three unique rare cases of chemotherapy-resistant advanced soft tissue sarcoma (STS) who achieved durable partial responses and disease control with SNK01 plus an immune checkpoint inhibitor. **Methods:** Three patients with chemotherapy-resistant soft tissue sarcoma participated in FDA authorized and WIRB approved protocols. Cases #1 with desmoplastic small round cell tumor (DSRCT) received SNK01 (2 x 10^9 cells) and pembrolizumab 200 mg i.v. q 3 weeks. Cases #2 with radiation-induced chondrosarcoma (RIC) received SNK01 (4 x 10^9 cells) and pembrolizumab 200 mg i.v. q 3 weeks. Case #3 with undifferentiated spindle cell sarcoma was enrolled in the SK01-US01 study and received SNK01 (4 x 10^9 cells) i.v. q 2 weeks and avelumab 800 mg i.v. q 2 weeks. **Results:** Case #1(DSCRT): The tumors gradually decreased in size over one year to a 47% response. Patient then underwent a surgical debulking procedure followed by whole abdominal radiation and intraperitoneal chemotherapy, after which he resumed SNK01 and pembrolizumab regimen. His last scan showed no evidence of disease. He has now received 42 cycles of SNK01 + pembrolizumab over 38 months and has an Eastern Cooperative Oncology Group score of 0 (fully active, able to carry on all pre-disease performance without restriction. The reported median overall survival for advanced STS is 8-13 months. Case #2 (RIC): Patient had a 38% partial response after four months of treatment, underwent debulking surgery but died of post-surgical infection. The patient had received 18 cycles of SNK01 + pembrolizumab and survived 12 additional months. Case #3 (Undifferentiated spindle cell sarcoma): Patient had durable disease control (stable disease), has received 37 treatment cycles during the 17-month treatment period. The best reported median progression free survival for previously treated advanced STS is 4.1 months. Grade 3 or greater adverse events include hypothyroidism (n=1), increased ALT (n=1), increased alkaline phosphatase (n=1) and increased GGT (n=1) which were attributed to immune checkpoint inhibitor therapy. **Conclusion:** These unique case studies clearly demonstrate the potential of SNK01 in controlling tumor growth in conjunction with an immune checkpoint inhibitor with manageable toxicity. Further clinical trials need to be conducted to confirm these promising results.

1137 Acid Degradable Lipid Nanoparticles Efficiently Deliver mRNA

Niren Murthy

University of California, Berkeley, Berkeley, CA

The development of acid degradable linkages that rapidly hydrolyze at endosomal pHs is a central problem in the field of drug delivery and have been challenging to develop because of their instability. In this presentation we present a new class of acid degradable linkers based upon acetals that have an azide in their para position, which rapidly hydrolyze at endosomal pHs but have exceptional stability at pH 7.4 and solve the instability problems associated with using unstable acid degradable linkages. Azide-acetals hydrolyze via a two-step mechanism based upon reduction and acid hydrolysis, and this gives them a unique combination of stability and rapid triggerable hydrolysis. Azide acetals have a hydrolysis half-life of 129 hours at pH 7.4 and are stable enough to synthesize and incorporate into delivery vectors, however after in situ reduction with DTT they hydrolyze with a half-life of 17 minutes at pH 6.0 and rapidly degrade in endosomes. In this presentation, we used the azide-acetal linker to develop three new class of acid degradable lipids, consisting of PEG-lipids, cationic lipids and anionic lipids, which were significantly better at transfecting cells and mice than traditional lipids used in LNPs. Collectively, these experiments demonstrate the versatility of the azide-acetal linker and its potential as a platform for developing acid sensitive delivery vectors.

1138 Correlative Findings Following DSG3-CAART Infusion with and without Combination Preconditioning Therapy in Patients with Pemphigus Vulgaris (DesCAARTes Study)

[1]Cabaletta Bio, Philadelphia, PA,[2]Northwestern University, Evanston, IL,[3]University of Washington, Seattle, WA,[4]University of Pennsylvania, Philadelphia, PA,[5]University of California, Davis, Davis, CA,[6]Stanford, Stanford, CA,[7]Fred Hutchinson Cancer Center, Seattle, WA

Mucosal-dominant pemphigus vulgaris (mPV) is a painful autoimmune blistering disease mediated by anti-desmoglein 3 autoantibodies (anti-DSG3 Ab). The current standard of care for mPV includes broadly immunosuppressive therapies that have risks of serious or life-threatening infection. We are evaluating the safety and activity of a novel cellular therapy consisting of gene-modified autologous T cells (DSG3-CAART) engineered to eliminate DSG3 reactive B cells in mPV. We previously reported on the translational and clinical data from mPV subjects receiving escalating doses of DSG3-CAART ranging from 1 x 10^5 to 7.5x10^9 transduced cells without preconditioning (NCT04422912). Manufactured DSG3-CAART eliminated target cell lines in vitro and were comprised of a mixture of effector and memory cells. DSG3-CAART cells were detected in the blood of all subjects within the first 29 days post-infusion with a dose dependent increase in peak persistence and persistence AUC for the first 29 days (AUC_{29d}), which reached a plateau at a dose of 2.5x10^9 DSG3-CAART cells. Here, we expand on those findings by including subjects who received combination therapy consisting of intravenous immune globulin (IVIG) to reduce potentially neutralizing autoantibodies and cyclophosphamide to reduce leukocytes followed by an infusion of 2.5x10^9 DSG3-CAART cells. Both peak persistence and persistence AUC_{29d} were further elevated in subjects receiving the combination therapy than those subjects receiving DSG3-CAART alone. Although persisting cells were predominantly of the central memory or stem cell memory phenotype in both groups, initial data from combination therapy subjects suggest that persisting DSG3-CAART cells exhibited signs of increased activation, including increased HLA-DR expression on DSG3-CAART cells, that were not observed in the DSG3-CAART cells in non-combination therapy subjects. Furthermore, in subjects receiving combination therapy, transient (< 2 weeks) leukopenia and neutropenia were observed but without lymphopenia. These data suggest that combination therapy with IVIG and cyclophosphamide enhances DSG3-CAART persistence and activation and support continued exploration of DSG3-CAART for mPV patients.

1139 Safety and Efficacy of EXG102-031, a Novel AAV-Based Gene Therapy for Neovascular AMD

Zhenhua Wu[1], Li Dai[1], Chunjuan Song[1], Jikui Shen[2], Raquel Formica[2], Lijun Wang[1], Peter A. Campochiaro[2], Guo-Jie Ye[1]

[1]Exegenesis Bio Inc., Lower Gwynedd, PA,[2]Johns Hopkins Hospital School of Medicine, Baltimore, MD

Age-related macular degeneration (AMD) is the most common cause of visual impairment among elderly. An estimated 20 million Americans aged 50 and older were living with AMD and patient numbers are predicted to increase with time. Approximately 10% of the AMD patients develop neovascular AMD, which is also called wet or exudative form of AMD (wAMD). EXG102-031, designed for the treatment of wAMD, is a recombinant adeno-associated virus (rAAV) expressing a fusion protein of angiopoietin 2-binding domain (ABD) and VEGF receptors (VEGFR) that is able to bind all known subtypes of VEGF as well as the angiopoietin 2 (Ang2). In the pharmacological studies, we first demonstrated that the fusion protein expressed from EXG102-031 was able to bind the three representative target ligands (VEGF-A, VEGF-C, and Ang2) *in vitro*. Furthermore, the efficacy of EXG102-031 for the treatment of neovascular AMD were comprehensively evaluated in laser-induced choroidal neovascularization (CNV) models (mouse and cynomolgus monkeys), as well as the *Tet/opsin/VEGF* double transgenic mice. The safety of EXG102-031 following a single subretinal injection of EXG102-031 was assessed in a GLP-compliant toxicology and biodistribution study in cynomolgus monkeys. EXG102-301 demonstrated strong *in vivo* efficacies in dose-range finding (DRF) studies in three different AMD models, laser-induced CNV in NHP, laser-induced CNV in mouse, and the *Tet/opsin/VEGF* double transgenic mice. It is worth to note that in the DRF study in *Tet/opsin/VEGF* double transgenic mice, the total retinal detachment was reduced by 80% after the injection of 1×10^9 vg and 100% after the injection of 7×10^9 vg/eye of EXG102-031. Mice in the positive control group received AV8-antiVEGFfab vector (expressing Ranibizumab) at a dose of 5×10^9 vg/eye showed an inhibitory effect on retinal detachment comparable to that found in the 1×10^9 vg/eye dose group received EXG102-031. The safety of EXG102-031 delivered via a single subretinal injection was comprehensively evaluated in a GLPcompliant toxicology study in NHP. EXG102-031 was well tolerated and did not cause any apparent systemic toxicity following a single subretinal injection at doses of 2×10^{10}, 1×10^{11}, and 5×10^{11} vg/eye in NHP. Subretinal injection induced transient and reversible ocular inflammation in the early phase including in the Vehicle control group. Following subretinal administration, EXG102-031 was mainly distributed in the ocular tissues of NHPs. Except for a low level of vector genomes detected in spleen, epididymis, liver, bladder lymph nodes and lung in a subset of the animals, vector genome in remaining tissues of most animals was not detected. Taken together, these nonclinical pharmacology and toxicology studies strongly support clinical development of gene therapy with EXG102-031 for treatment of patients with neovascular AMD. A phase I clinical study is planned to evaluate the safety and tolerability of EXG102-301.

1140 A Lentiviral Vector-Based Gene Therapy Product for the Treatment of Wilson Disease

Cheen Khoo, Suzan M. Hammond, Sarah Sherrington, Laura Martins, Robert J. Powles, Vicky Kennedy, Efrain Guzman, Deirdre O'Connor, Kyriacos Mitrophanous, Yatish Lad

Oxford Biomedica, Oxford, United Kingdom

Wilson Disease (WD) is an inborn error of metabolism caused by mutations in a copper transporter ATPase copper transporting beta polypeptide (ATP7B). This results in impaired function of the protein and accumulation of copper in organs, primarily the liver but also in the brain and the eye. Untreated, the accumulation of copper in these organs causes damage and can result in liver failure. The current treatments for WD, metal chelators, aim to remove excess copper, reducing intracellular copper and preventing its re-accumulation. Although the use of systemic copper chelators is relatively successful in controlling symptoms, the costs of these life-long therapies is very high, the side effects can be intolerable to many patients resulting in reduced compliance, and ultimately the underlying disease mechanism remains unresolved which may require liver transplantation. Gene therapy offers the opportunity to treat WD patients by providing a corrected copy of the gene and removing the necessity for life-long medication. The ATP7B gene is 4.4 Kb long and beyond the capacity of AAV vectors. To solve this issue, the size of the open reading frame can be reduced, or an alternative vector system can be used. Lentiviral vectors (LVV) have the capacity to accommodate the full length ATP7B gene. LVV also have the advantage of integrating into the host genome and providing long-term stable transgene expression from a single administration. This is of particular importance when targeting organs such as the liver, which have a high turnover rate especially in paediatric patients; in these patients, use of an AAV vector would result in loss of expression to below therapeutic levels as the cells divide over time. A HIV vector encoding human ATP7B using a hepatocyte-specific promoter was evaluated in a WD cell model *in vitro.* This vector demonstrated cell protection from copper induced toxicity. Transgene expression was sustained *in vitro* over 31 days. This vector was then evaluated in a juvenile Atp7b-/- mice, a model for WD. Analysis of the relevant biomarkers and survival will be presented. We have demonstrated efficacy *in vitro* and *in vivo* with an HIV vector expressing full length ATP7B which has the ability to stably integrate and provide long term gene expression following a single administration. This efficacy data taken together with Oxford Biomedica's ability to produce high quantities and quality of clinical and commercial grade vector provides a robust approach to treat Wilson Disease.

1141 Automated Manufacture of dNPM1 TCR-Engineered T Cells for Therapy

Isabella Elias Yonezawa Ogusuku[1], Vera Herbel[1], Simon Lennartz[1], Caroline Fabian[1], Caroline Brandes[1], Karin Teppert[1], Carola Barth[1], Sabrina Veld[2], Lois Hageman[2], Conny Hoogstraten[2], Georgia Koutsoumpli[2], Marieke Griffioen[2], Thomas Schaser[1], Rosa de Groot[2], Ian Johnston[1], Dominik Lock[1]

[1]Miltenyi Biotec B.V. & Co. KG, Bergisch Gladbach, Germany,[2]Department of Hematology, Leiden University Medical Center, Leiden, Netherlands

Treatment of relapsed or refractory acute myeloid leukemia (AML) still represents a challenge for physicians and is mainly associated with poor prognosis with a 5-year survival rate in Europe of only 25%. A neoantigen encoded by mutated nucleophosmin 1 (dNPM1) is expressed in approximately 30% of patients and presents an attractive target for immunotherapy with T cell receptor (TCR)-engineered T cells. Manufacturing of TCR-modified T cells, however, is still limited by a complex, time-consuming and laborious procedure. Therefore, this study specifically addressed the requirements for a scaled manufacture of dNPM1-specific T cells in an automated, closed and Good Manufacturing Practice (GMP)-compliant process using the CliniMACS Prodigy. Small scale studies demonstrated that the HLA-A*02:01 restricted recombinant TCR is dependent on CD8 co-receptor interaction to bind the peptide-HLA complex with high affinity. We therefore focused on the development of a CD8 T cell-specific process. Thus, in 23 individual runs, 2E8 CD8-positive T cells were enriched from cryopreserved leukapheresis, subsequently activated, lentivirally transduced, expanded and finally formulated. By adjusting and optimizing culture conditions, we additionally reduced the manufacturing time from twelve to eight days while still achieving a clinically relevant yield of up to 5.5E9 dNPM1 TCR-engineered T cells (4.2E9 ± 1.4E9). The cellular product mainly consisted of highly viable CD8-positive T cells (97.5% ± 0.978%) with an early memory phenotype. The cellular product was stable for up to 48h. Overall, mean vector copy number was 2.9 ± 1.1. Importantly, TCR-engineered T cells specifically lysed dNPM1-positive target cells *in vitro* as well as *in vivo*. In conclusion, we demonstrated that our CD8 process is robust and reproducibly yielded suitable numbers of potent dNPM1 TCR-engineered T cells, preparing the way for initiating a clinical trial to treat patients with relapsed or refractory AML.

1142 Immune Response to AAV Vector Capsid and Assessment of Eligibility for AAV-Mediated Gene Therapy for Duchenne Muscular Dystrophy

Rima Saha[1], Craig Meyers[1], Kirsten Coleman[2], Prasad Trivedi[3], Radhika Bhake[1], Barry J. Byrne[2], Manuela Corti[2]

[1]Pediatrics, University of Florida, Gainesville, FL,[2]University of Florida, Gainesville, FL,[3]University of Florida, Powell Gene Therapy Center, Gainesville, FL

Despite advances in AAV gene therapy, the field still faces a crucial unresolved challenge of the host immune response against vector capsid proteins. We hypothesize that our proposed immunosuppression

regimen can reverse humoral and cellular responses in mice with pre-existing immunity for AAV and will allow safe AAV9-μDysUF administration and increase dystrophin expression in mice. We have developed an optimal microdystrophin (AAV9-μDysUF) that improves exhaustion and *in vivo* and *ex vivo* muscle force compared to μDys5* and GFP-injected *mdx* mice. Utilizing the wildtype C57BL/6 mouse, we injected empty AAV9 capsids in mice to mimic pre-existing immunity in human patients. We collected serum samples from mice on Day 0 before injection. The mice were then injected with empty capsids at a dose of $1X10^{12}$ vg/kg on day 0 to induce an approximate level of anti-AAV antibodies of 150U/ml. Four weeks later, after collecting serum, the same animals (N = 6) received different immunosuppression drugs, either alone or in combination with other drugs. The immunosuppression drugs are velcade, darzalex, anti-CD20 antibody, and sirolimus. The animals were maintained in these drug regimens until day 70. On day 70, serum was analyzed from these groups. We measured the anti-AAV titers at days 0, 22 and 70 and compared the respective time points to animals with no immunosuppression. We found a **significant decrease in AAV antibody titers** between no immunosuppression and animals on immunosuppression drugs. At day 70, sera from animals treated with antiCD20 antibody+sirolimus show 33%, velcade show 60%, darzalex show 60%, antiCD20 antibody+sirolimus+velcade show 88% and antiCD20 antibody+sirolimus+darzalex show 51% reduction in anti AAV9 titer respectively. This decrease in anti-AAV9 titer is significant compared to no immunosuppression group. Furthermore, we plan to implement the best immunosuppression regimens for safe AAV9-μDysUF administration and increase dystrophin expression in mice. We are implementing immunomodulation strategies like an induction regimen before a high dose (1E14vg/kg), two low doses (5E13vg/kg), a maintenance regimen of anti-CD20 antibody, and sirolimus during the study to analyze which dose will provide optimal microdystrophin expression.

1143 Transitioning from Adherent to Optimized and Scalable Suspension-Based Production of CAR-Lentivirus (LV)

Anna Maystrenko[1], Adam Mcleod[1], Daniel Chettiar[2], Arun Kumar Annan Sudarsan[2], Philip Beaudette[2], Hadel Al Asafen[1], Karina Kawka[1], Azher Razvi[1], Krista McNally[3], Albert Gacerez[3], Melissa Fardy[3]

[1]Cytiva, Toronto, ON, Canada,[2]CCRM, Toronto, ON, Canada,[3]Chimera Bioengineering, South San Francisco, CA

The number of lentiviral-based chimeric antigen receptor (CAR) T cell therapies in development pipelines continues to grow substantially. Lentiviral vectors (LVV) have proven to be an efficient mechanism for the delivery of genetic material to T cells. However, depending on the strategy, the production of these vectors can come at a high cost. While adherent cell lines, such as HEK293T cells grown in static culture, have traditionally been the first choice for LVV production, the scalability and automation of these approaches is limited and costly. Conversely, suspension-adapted cell cultures grown in stirred-tank bioreactors can scale to volumes upwards of thousands of liters in a single batch. Unlike adherent cells, suspension-based cultures aren't serum-dependent, which makes them a more appealing candidate for commercial manufacturing. The aim of this work was to optimize the transient-transfection conditions for a preclinical CAR construct and scale the process to meet anticipated manufacturing needs for clinical trials. A Good Manufacturing Practice (GMP)-compliant HEK293 suspension cell line was chosen for this process. Previously, the optimal viable cell density (VCD) at transfection, total amount of DNA, and other conditions were determined using a Green Fluorescent Protein (GFP) construct. Using a Design of Experiments (DoE) approach, a series of three iterative transfection experiments were conducted at small-scale. For each experiment, two factors were varied: the percentage of CAR transfer plasmid relative to total DNA and the ratio of the packaging plasmids. Scale-up in 1 L shake flask cultures was completed using the top two performing conditions identified in the DoE, followed by bench-scale demonstration in bioreactor cultures. Baseline production for this CAR-LVV in an adherent HEK293T cell line was determined to be 2×10^7 TU/mL. After optimization, the suspension-based upstream process consistently yielded between 1×10^8 to 1.2×10^8 TU/mL.

1144 Intratumoral Delivery of CRISPR-Cas9 Using Lipid Nanoparticles Enables Efficient Gene Editing and Restores Chemosensitivity in Lung Squamous Cell Carcinoma

Kelly Banas, Nicole Haas, Komal Khan Iqbal, Emily Gielda, Krishna Priya Narra, Pawel Bialk, Natalia Rivera-Torres, Katelynn Owens, Byung-Chun Yoo, Eric B. Kmiec

ChristianaCare Gene Editing Institute, Newark, DE

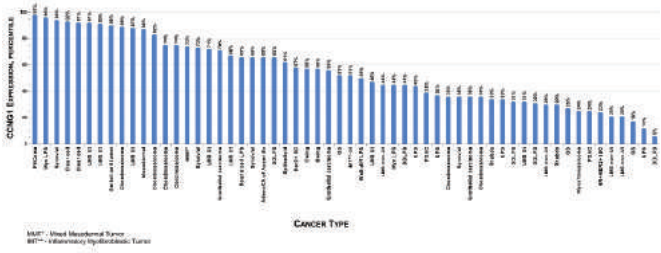
Recent studies point to the evolution of drug resistance in non-small-cell lung cancer (NSCLC) as being centered, at least in part, on the upregulation of various genes involved in controlling efflux and drug metabolism. Among the most important of these genes is Nuclear Factor Erythroid 2-Related Factor (NRF2), considered the master regulator of over 100 target genes involved in cellular responses to oxidative and/or electrophilic stress. We are utilizing a combinatorial approach in which CRISPR-directed gene editing is used to disable NRF2 in order to augment standard-of-care chemotherapy treatment. We developed and optimized lipid nanoparticles (LNP) to deliver Cas9 mRNA and a single guide RNA (sgRNA) targeting mutant NRF2, as an intratumoral injection. We show our single guide RNA distinguishes the genome of a tumor cell and a normal cell, thereby conferring target selectivity onto this therapeutic approach. We also show efficient gene editing activity after intratumoral LNP-mediated delivery of CRISPR/Cas9 in vitro and in vivo, with limited biodistribution and low off-target profile. We will discuss our progress in developing this CRISPR-based gene therapy.

1147 Enhanced CCNG1 Expression in Tumors May Predict Clinical Benefit from DeltaRex-G, a Tumor Targeted Retrovector Encoding a CCNG1 Inhibitor Gene

Erlinda M. Gordon[1,2], Nadezhda Omelchenko[3], Caroline Eid[4], Samantha Jeffrey[5], Elan Younesi[3], Neal Chawla[6], Zhanna Shekhovtsova[7], Aleksei Omelchenko[3], Kushal Suryamohan[8], Don Brigham[2], Michael Morse[9], Sant P. Chawla[3]

[1]Medical Oncology, Sarcoma Oncology Research Center, Santa Monica, CA,[2]Medical Oncology, Aveni Foundation, Santa Monica, CA,[3]Medical Oncology, Sarcoma Oncology Center, Santa Monica, CA,[4]Dornsife College of Arts and Letters, University of Southern California, Los Angeles, CA,[5]University of California Los Angeles, Los Angeles, CA,[6]Medical Oncology, City of Hope, Duarte, CA,[7]Medical Oncology, Boston Gene, Inc., Waltham, MA,[8]Medical Oncology, Boston Gene, Waltham, MA,[9]Medical Oncology, Duke University Medical Center, Durham, NC

Background: Metastatic cancer is associated with an invariably fatal outcome. Therefore, innovative therapies are urgently needed. Although expanded access for DeltaRex-G, a tumor targeted retrovector encoding a CCNG1 inhibitor gene, is on-going for an intermediate-size (n= up to 40) population of advanced sarcoma and pancreatic cancer, more data is needed to identify patients who are likely to benefit from DeltaRex-G gene therapy. In this study, we retrospectively analyzed CCNG1 expression in archived tumors of patients who were previously treated with DeltaRex-G and who are active candidates for DeltaRex-G therapy. **Methods:** Archived formalin-fixed paraffin embedded (FFPE) tumor specimens (n=58) from patients with solid malignancies who are actively followed at the Cancer Center of Southern California were collected, processed, and subjected to RNA sequencing. Briefly, RNA-seq libraries were sequenced to generate 50 million reads that were aligned using Kallisto v0.42.4 to GENCODE v23 transcripts with default parameters. Only protein-coding, IGH/K/L- and TCR-related transcripts were retained for downstream processing, resulting in 20,062 protein coding genes. Gene expression was quantified as transcripts per million (TPM) and log2-transformed. A gene expression level is presented as low/medium/high depending on the expression level of a such gene in patients of the reference cohort. Low = <17%; Medium = 17%-83%; High = >83%. **Results:** Thirty-two male and 26 female subjects, ages ranging from 16 to 86 years were studied. Forty-nine (84.4%) patients had sarcoma, 3 (5.2%) had urothelial carcinoma, 2 (3.5%) had breast carcinoma, 2 (3.5%) had pancreatic cancer, 1 (1.7%) had Sertoli cell tumor, 1 (1.7%) had adenocarcinoma of appendix. Eleven (19%) tumors showed high CCNG1 expression, 44 (76%) tumors had medium expression, and 3 (5.2%) tumors had low CCNG1 expression. Of note, the tumor of one 14-year survivor with metastatic pancreatic adenocarcinoma in sustained remission had 24 % CCNG1 expression, one 3-year survivor with metastatic chondrosarcoma metastatic to lung with stable disease had 74% CCNG1 expression, one 2-year survivor with early stage HR+ HER2+ breast cancer in remission had 23% CCNG1 expression, and one 2-year survivor with early stage triple negative breast cancer in remission had 74% CCNG1 expression. **Conclusion:** Taken together, these data indicate that (1) Medium to high CCNG1 expression was found in 95% of tumors studied, and (2) Patients with medium CCNG1 expression who received DeltaRex-G had clinical benefit and are alive in sustained remission or with stable disease 2-14 years from DeltaRex-G treatment initiation, and (3) Prospective studies are warranted to correlate CCNG1 expression level and response to DeltaRex-G therapy.



1148 An Automated, Closed Magnetic Cell Separation System for Both Autologous and Allogenic Cell Therapy Development

Silin Sa, Liping Yu

Applied Cells, Santa Clara, CA

Adoptive cell therapy has proven clinical efficacy in many cancer types and the success has driven more development of new drugs. However, on the manufacturing side, current process using conventional tools is complicated and results in suboptimal purity and yield sometimes. All those shortcomings may contribute to the high cost of the cell products and limit the patients access to drugs. Cell therapy developers in both industry and academic settings are trying to improve their manufacturing process aiming to increase efficiency and lower cost. Cell selection done with magnetic beads antibody conjugate is an important step in cell manufacturing: it is either the first step to isolate T cells for gene modification or the last step to deplete subtype of T cells in allogenic transplantation, so a fast efficient magnetic cell separation system has been desired. We have developed an automated closed system (MARS® BAR) based on Applied Cells proprietary column-free matrix-free in-flow magnetic cell separation technology. The system can deal with diverse cell sources without requiring cell washing before or after labeling, thus it makes the cell selection workflow very simple. The MARS® BAR system has no capacity limit and is easy to scale-down or scale-up, which make it suitable for both autologous and allogenic cell therapy manufacture. Here we present the results of CD4/CD8 T cell isolation from fresh leukopak using MARS® BAR and its closed fluidic kit. Cells were labeled with CD4 and CD8 nano magnetic beads in the bag and diluted in the bag before the magnetic separation. The positive selection program ran through up to 120million cells per minute and resulted in >90% purity and >85% recovery of T cells. In the followed cell activation and expansion, we proved the unaffected viability and functionality of the isolated T cells. We also present the results of TCR αβ+ cell depletion from PBMC to demonstrate the capability of purifying cells in allogenic cell therapy manufacturing. In the automated process cells were only passing the magnetic separation channel once and 99.9% depletion of TCR αβ+ cells with 90% recovery of TCR γδ cells was achieved. The magnetic cell selection using MARS® BAR automated closed system shortens the process time and increases the yield of target cells comparing to conventional tools therefore it shows the potential to help lower the manufacturing cost.

The system is built for a GMP-compliant environment and provides a new solution for cell selection in both autologous and allogenic cell therapy development.

1149 Reversion of Non-Alcoholic Steatohepatitis by Skeletal Muscle-Directed FGF21 Gene Therapy

Veronica Jimenez, Victor Sacristan, Claudia Jambrina, Maria Luisa Jaen, Estefania Casana, Sergio Muñoz, Miquel Garcia, Ignasi Grass, Xavier Leon, Ivet Elias, Albert Ribera, Gemma Elias, Victor Sanchez, Alba Casellas, Tura Ferre, Maria Molas, Fatima Bosch

Universitat Autonoma de Barcelona, Bellaterra, Spain

Non-alcoholic steatohepatitis (NASH) is a severe form of nonalcoholic fatty liver disease, which is driven by the global obesity and type 2 diabetes epidemic. NASH is characterized by liver inflammation and fibrosis that can progress to cirrhosis, liver failure, cancer and death. Currently, NASH is an unmet medical need. Here, we demonstrated that adeno-associated viral (AAV) vector-mediated-FGF21 genetic engineering of skeletal muscle of high-fat diet-fed obese and insulin-resistant mice resulted in increased circulating levels of native FGF21. AAV-FGF21-treatment normalized liver fat content, liver inflammatory and fibrotic markers and counteracted hepatocyte damage, consistent with NASH resolution. It also precluded progression from NASH to cirrhosis and hepato-cellular carcinoma. Moreover, circulating FGF21 reversed adipose tissue hypertrophy and inflammation, increased energy expenditure, normalized glycemia and insulinemia, and increased insulin sensitivity. Scale-up of muscular FGF21 gene transfer to large animals also successfully resulted in long-term secretion of biologically active FGF21 and therapeutic effects in key target tissues, in the absence of adverse events. All these results point out the potential of the AAV-FGF21-mediated gene therapy to treat NASH and support the clinical translation of the approach.

1150 Targeted Exon Skipping of DMD Exons 51 and 53 Using PAM-Less Base Editors

Jackson Winter[1], Michael Gapinske[1], Wendy Woods[1], Shraddha Shirguppe[1], Angelo Miskalis[1], Riley Lehmann[1], Peyton Muehlhauser[1], Pablo Perez-Pinera[1,2]

[1]Department of Bioengineering, University of Illinois at Urbana-Champaign, Urbana, IL,[2]Cancer Center at Illinois, UIUC, University of Illinois at Urbana-Champaign, IL

Duchenne Muscular Dystrophy (DMD) is a devastating X-linked monogenic disease caused by mutations in the *DMD* gene that prevent production of a functional dystrophin protein leading to progressive skeletal and cardiac muscle degeneration, and ultimately death. Exon skipping has emerged as a promising treatment modality for many DMD cases by circumventing disruptive mutations and restoring the reading frame of the dystrophin gene to drastically improve the symptoms of the disease. While the FDA approved antisense oligonucleotides (AONs) for exon skipping, they require repeated injections to achieve a mild effect and their cost is very high. Alternatively, CRISPR-Cas9 has revolutionized the field of genome editing and has been harnessed for exon skipping through disruption of splice sites by creating targeted double strand breaks (DSBs). While Cas9 mediated exon skipping of various exons within *DMD* has been successfully demonstrated, the drawbacks of creating DSBs, such as chromosomal translocations, unpredictable editing outcomes, and a TP53 DNA damage response that compromises the survival of edited cells, severely limit this approach. To overcome these limitations we have previously developed a gene editing platform termed CRISPR-SKIP that uses CRISPR-Cas9 single base editors to achieve permanent exon skipping by directly mutating splice sites within the DNA without creating a DSB. Although this technique can be applied to skip many exons, the availability of an appropriately positioned protospacer adjacent motif (PAM) sequence that places the targeted base within the editing window of the BE can prevent the targeting of exons that are therapeutically relevant. Here we demonstrate the use of an engineered PAM-less SpRY-Cas9 base editor coupled to an evolved ABE8e deaminase domain to target and edit the splice sites of *DMD* Exons 51 and 53, the two exons that when skipped, would treat the largest DMD patient populations but whose splice acceptors have been resistant to editing with wild-type Cas9. We first systematically optimized our CRISPR-SKIP approach for these targets by testing a large panel of single guide RNAs targeting the splice acceptors and splice donors to identify the guides that maximize editing rates of these sites. We next developed a novel human myoblast DMD disease model harboring a deletion of exon 52 which can be corrected through skipping of exon 51 or exon 53. This cell culture model was then used to evaluate the DNA editing efficiency and exon skipping rates following delivery of our optimized CRISPR-SKIP system, and to evaluate the restoration of dystrophin protein expression after differentiation into muscle tissue in a 3D scaffold. This work provides valuable preclinical data on the use of CRISPR-SKIP as a therapy for DMD, and demonstrates the enormous therapeutic potential of using PAM-less base editors to treat human disease.

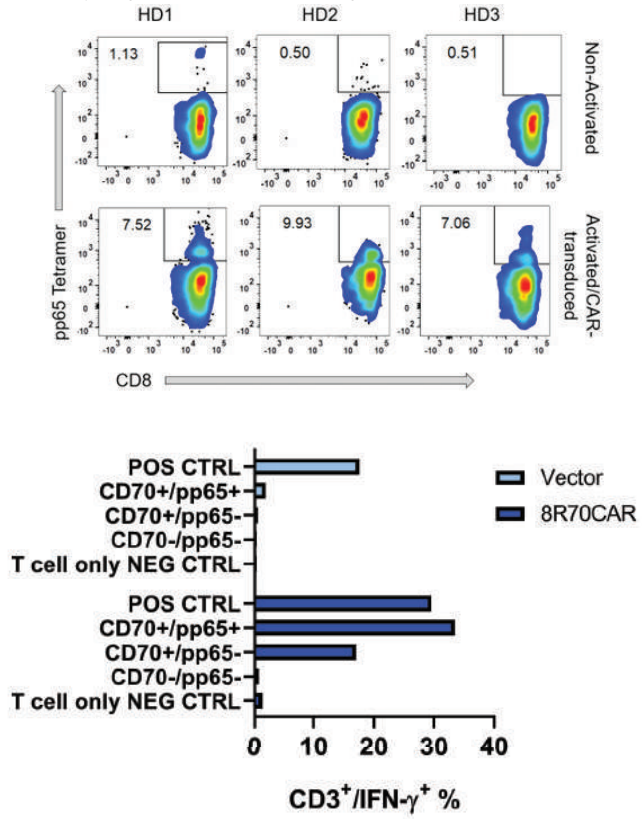
1151 CAR T Cell Production Expands Endogenous T Cell Repertoire Recognizing Additional Tumor Antigen(s)

Alicia Hou, Linchun Jin, Haipeng Tao, Duane A. Mitchell, Jianping Huang

Neurosurgery, University of Florida, Gainesville, FL

BACKGROUND: Glioblastoma (GBM) is an aggressive and heterogeneous brain tumor that currently has no curative treatment. Our group identified CD70, which is overexpressed by low-/high-grade gliomas and associated with poor patient survival. We established a CAR-T cell therapy platform targeting CD70-expressing gliomas, which showed efficient antitumor activity preclinically. Modification of CD70CAR to express IL-8 receptors (8R-70CAR) enhanced tumor trafficking and persistence, resulting in improved antitumor efficacy and long-lasting immunity to tumor rechallenge. These findings culminated in a phase I trial of 8R-70CAR T cells (NCT05353530) for patients with newly diagnosed GBM that will begin this year. However, CAR T cell therapy currently faces obstacles such as single antigen targeting in heterogeneous tumors and maintenance of activation of CAR T cells. Cytomegalovirus pp65 protein is a tumor-specific target in GBM. A combinatorial approach against CD70 and pp65 may result in enhanced effect against heterogeneous GBM. **OBJECTIVE:** Generate and test CD70 and pp65 dual-target T cell therapy against GBM. **METHODS:** Healthy donor peripheral blood mononuclear

cells were stimulated with anti-CD3/CD28 Dynabeads and retrovirally transduced with 8R-70CAR. Frequencies of 8R-70CAR- and pp65-specific T cells were evaluated by flow cytometry. **RESULTS:** The pp65-specific CD8+ T cell population was expanded post DynaBeads activation to a frequency tenfold over baseline (Fig. 1). Single-specific (CD70 CAR+ only and pp65-specific only) and double-specific (CD70 CAR+ and pp65-specific) T cells were successfully generated. Importantly, these cells secreted greater IFN-g when tumor cells expressed both targets (Fig. 2). **CONCLUSION:** The CAR T cell production process significantly expands pp65-specific T cells, resulting in enhanced antitumor efficacy through recognition of both tumor targets. Our CAR T cell product may contain T cell repertoires that effectively target multiple tumor antigens.



1152 G-CSF-Free HSC Mobilization with WU-106/AMD3100 Allows for Safe and Efficient *In Vivo* HSC Transduction and *In Vivo* Prime Editing of the Sickle Cell Disease Mutation in a Mouse Model

Chang Li[1], Hans-Peter Kiem[2], Peter Ruminski[3], Michael Rettig[3], Darja Karpova[3], John F. DiPersio[3], Andre Lieber[1]

[1]University of Washington, Seattle, WA,[2]Fred Hutch, Seattle, WA,[3]Washington University School of Medicine, St Louis, MO

We have previously developed a new *in vivo* HSC gene therapy approach that does not require myeloablation/conditioning and HSC transplantation. In this approach, HSCs are mobilized from the bone marrow into the peripheral blood stream and transduced with intravenously injected helper-dependent adenovirus (HDAd5/35++) vectors that target human CD46, a receptor that is abundantly expressed on primitive HSCs. HSCs transduced in the periphery return to the bone marrow and spleen and persist there long-term. The approach has recently been used for *in vivo* editing of HSPCs to correct the Sickle Cell Disease mutation in erythroid cells of CD46/Townes mice ($CD46^{+/+}$/ hα/hα::β^S/β^S triple homozygous mice) a mouse model for SCD. In that study, we mobilized cells by injection of G-CSF for 5 days followed by one injection of the CXCR4-inhibitor AMD3100. G-CSF treatment is known to trigger leukocytosis and release of pro-inflammatory cytokines from granulocytes and is thought to cause critical toxic side effects in SCD patients. Recently, we developed a simpler, rapid, and more HSC-selective mobilization regimen using truncated GRO-β (MGTA-145), a CXCR2 agonist, and plerixafor/AMD3100. We demonstrated that it mediated efficient mobilization and *in vivo* transduction of HSCs with β-thalassemia correction in mice. Among the alternative G-CSF-free mobilization protocols is also plerixafor plus small molecule VLA4 antagonists, such as BIO5192 or its improved derivatives (e.g. WU-106). Here we tested WU-106 plus AMD3100 mobilization for *in vivo* HSC transduction with a SCD prime editing vector (HDAd-PE5max) in CD46/Townes mice (N=7). Two hours after subcutaneous injection of WU-106 + AMD3100, mice received one intravenous injection of HDAd-PE5max. To expand edited cells, *in vivo* selection with low-dose O^6BG/BCNU was implemented on days 6, 19, and 33 while the episomal HDAd vector was still present in HSPCs. Mobilization with WU-106 + AMD3100 in CD46/Townes was efficient (and comparable to the G-CSF/AMD3100 regimen) as reflected by the presence of (on average) 10^5 $Lin^-/Sca1^+/c\text{-}kit^+$ (LSK) cells and 10^4 colony forming units (CFU) per ml peripheral blood at 3 hours after mobilization drug injection. In contrast to the GCSF/AMD3100 approach, leukocytosis was minimal and serum cytokines (IL-6, TNF, IFN-γ) were not detectable after WU-106+AMD3100. SCD target correction was measured in PBMCs by Sanger sequencing. At week 6 after *in vivo* transduction, editing rates at the T>A site (SCD repair) site were in the range of 15 to 33% in the seven mice (average 20%). Prime editing is independent of double-strand DNA breaks, and we have shown that *indels* on average were less than 1%, which is important for editing a coding region. Mice will be followed for 16 weeks and then HSCs will be transplanted into secondary recipients. Analysis of the percentage of β^S versus β^A globin in erythrocytes and phenotypic correction in primary mice (spleen size, histology, blood smears) will be reported. These first data indicate that HSC *in vivo* gene therapy using the new mobilization approach is safer than GSCF/AMD3100, can be done on one day, and can achieve therapeutically relevant correction levels of the SCD mutation in a relevant mouse model.

1153 The reiMMAgine Study: Evaluation of the Safety, Tolerability, and Pharmacodynamics of AAV8 Gene Therapy (MMA-101) in Combination with an Immunotolerance-Inducing Nanoparticle (ImmTOR) in MUT Subtype Isolated Methylmalonic Acidemia (MMA)

Rehan Azeem[1], Irini Manoli[2], Alicia Michaud[3], Jennifer L. Sloan[4], Sheri Rhodes[1], Sheldon Leung[3], Charles P. Venditti[2], Peter G. Traber[1]

[1]selecta biosciences, Watertown, MA,[2]NIH, Bethesda, MD,[3]Selecta Biosciences, Watertown, MA,[4]National Human Genome Research Institute, Bethesda, MD

MMA due to methylmalonyl-CoA mutase (MMUT) deficiency manifests as episodic metabolic decompensation with progressive decline in multiple organ systems. In severe patients, dietary and medical interventions fail to prevent metabolic instability and liver transplant is needed in some patients to reduce hospitalizations and improve survival. Liver directed gene therapy may present a viable alternative to liver transplantation for these patients. The reiMMAgine study has been designed to evaluate safety and efficacy of a systemic AAV8 gene therapy designed to express a liver targeted, wild-type *MMUT* (MMA-101; hAAT promoter, apoE enhancer) in *mut*^{0} MMA subjects. The study is an open-label, single dose level, single center (NIH) study of MMA-101 plus the immunomodulatory drug ImmTOR, which is nano encapsulated sirolimus. Previously we demonstrated in adult volunteers that ImmTOR inhibited the formation of anti-AAV8 neutralizing antibodies (NAb) following administration of AAV8 empty capsid in a dose-dependent manner at Day 30, but most subjects had an increase in NAb by day 90 [MOL THERAPY 2022:336-337)]. Therefore, eligible subjects will receive IV ImmTOR prior to the IV dose of MMA-101, as well as ImmTOR alone on days 28 and 56, for the purpose of mitigating long-term development of NAb. In addition, ImmTOR may enhance transgene expression as observed in animal studies and improve the safety of the gene therapy by ameliorating the cellular immune response-mediated liver injury and potentially reducing the need for chronic use of steroids and other immunosuppressants. Enrolled subjects will have a molecular genetic diagnosis of MMUT MMA AND serum methylmalonic acid (MMA) levels between 100 to 3,000 μmol/L AND a clinical history consistent with severe MMA by agreed criteria with the FDA. The study will treat up to a total of 6 subjects, 3 adolescents (≥12 and <18 years of age) in Cohort 1 followed by 3 children (≥3 and <12 years of age) in Cohort 2. MMA-101 will be administered at a dose of 1.0E13 vg/kg. The first subject in Cohort 1 of adolescent subjects will be treated with MMA-101 alone, with the addition of steroid prophylaxis. The second adolescent subject in Cohort 1 will be treated with IV of ImmTOR followed by MMA-101 on Day 1 and then ImmTOR on Days 28 and 56, without addition of steroids. The dose of ImmTOR in the third subject in Cohort 1 may be increased depending on immunologic assessment of anti-AAV8 NAb, ImmTOR pharmacokinetics, and safety in the second subject. Following safety and efficacy assessment of Cohort 1, Cohort 2 will be conducted in children (≥ 3 and <12 years old) in the same fashion, omitting the use of steroids in all three subjects. The primary endpoint for assessment of safety and efficacy will be one year following MMA-101 infusion, with interim assessment at 3 months to assess proceeding with next subject and/or escalating to the next cohort. All subjects will be followed for an additional 4 years. The endpoints include: 1) Safety and tolerability; 2) Pharmacodynamic response to MMA-101 assessed by reduction sMMA and an increase in the 1-13C -sodium propionate oxidation breath test; 3) Formation of AAV8 neutralizing antibodies (NAb); 4) clinical parameters including hospitalizations, metabolic crises, growth, diet, and subject-/caregiver-reported outcomes. In summary, this first-in-human clinical trial will establish the safety and efficacy of a liver-directed AAV8 gene therapy to treat subjects with *mut*^{0} MMA and assess the ability of the novel immunomodulatory drug ImmTOR to induce immune tolerance to the AAV8 vector.

1154 Development and Qualification of 4-plex Assay for AAV Vector Genome Integrity Evaluation by dPCR

David Dobnik[1], Nejc Jakoš[2], Nejc Košir[2], Rebecca Vollmeier Kovačić[2], Polona Kogovšek[1]

[1]National Institute of Biology, Ljubljana, Slovenia,[2]Niba Labs, Ljubljana, Slovenia

The production of viral vectors for gene therapy is focused on pure, safe, and efficacious products. Absence of impurities and presence of full vector genomes play a crucial role. We have addressed the problem of AAV vector genome integrity by developing an advanced dPCR multiplex approach. The newly developed 4-plex assay was qualified on DNA level and tested on several different AAV vectors to show its applicability. The assay is an upgrade from simplex vector genome titering assay by providing accurate quantitative result on genome integrity. The use of such assay can better guide process development with a goal of having as much full vector genomes as possible.

1155 Long-Term Seroconversion Risk Among a Cohort of Cynomolgus Macaques

Arpana Khatri[1], Marla Bazile[1], Kate Breyer[2], Jan Bernal[2], Maureen Hargaden[2], Judith Franco[2], Mikele Simkins[2], Rosemary Santos[2], Sury Somanathan[1]

[1]Pfizer Inc, Cambridge, MA,[2]Pfizer Inc, Groton, CT

AAV drug development has been aided by use of preclinical animal models to assess vector safety and efficacy. Among preclinical species, non-human primates have been an effective large animal model to interrogate drug efficacy and toxicity. However, AAV vector administration is ineffective in animals carrying neutralizing antibodies from a previous exposure. Such antibodies bind and neutralize vector resulting in reduced efficacy, modified biodistribution, and increased toxicity. Hence, only seronegative animals are included in AAV preclinical studies. Seronegativity is determined by prescreening animals for anti-AAV antibodies using either a cell-based neutralizing antibody (NAb) assay or an ELISA-based binding antibody (BAb) assay. However, even NAb negative animals risk seroconversion while awaiting study start which can led to reduced gene transfer. Here, we undertook a longitudinal study over 6 months to assess seroconversion risk among a cohort of cynomolgus macaques. Animals were prescreened and twelve AAV9 seronegative macaques (6/gender) were procured, shipped, and housed (2/cage) before study start. Several guidelines were implemented to reduce environmental

exposure while animals were housed. Animals were bled monthly, and serum investigated for anti-AAV9 antibodies. While animals were NAb negative before shipment, two out of the twelve animals (CIC018; female and CHE018; male) were AAV9 NAb seropositive (titers 5 and 40, respectively) before study start. Animals were positive for the study duration with no fluctuations in titer. Cage mates co-housed with the seropositive animals did not seroconvert suggesting a lack of transmission. BAb were marginally higher in the animal with higher NAb titer. The seroconversion of two animals to AAV9 led us to investigate NAb and BAb against a panel of AAVs belonging to different clades (AAV1, 2, 3B, 5, 6, and 8). Animal CHE018 had cross-reactive NAb to AAV8, albeit at lower levels, while CHF050 had higher NAb to AAV3B, and lower cross-reactive titers against AAV1 at all time points. IgM binding antibodies were higher in one animal (CIC023) against all AAVs at study start that declined below detection levels by 2 months. Surprisingly, there was no concordant increase in IgG levels against any AAV in this animal. Similarly, IgG levels peaked in two animals after 4 months without an expected prior increase in IgM levels. These findings suggest the risk of seroconversion of a naïve animal co-housed with a seropositive cage mate appeared to be low. Finally, while NAb titers were more stable, IgG and IgM binding antibodies fluctuated more during the study and were less predictive of seropositivity.

1156 Durability of AAV-Mediated Phenotypic Correction of Very Long-Chain Acyl-CoA Dehydrogenase (VLCAD) Deficiency in Mice

Pilar Prentiss[1], Amanda Tutto[2], Michele Stone[1], Rosemarie Roeloffs[1], Meghan Blackwood[2], Acadia Kopec[2], Jiewu Liu[1], Jason M. Mallory[1], Allison M. Keeler-Klunk[2]

[1]Kriya Therapeutics, Inc., Research Triangle Park, NC,[2]University of Massachusetts Medical School Gene Therapy Center, Worcester, MA

Previously, the authors presented results of modified adeno-associated virus (AAV)-ACADVL (gene encoding human very long-chain acyl-CoA dehydrogenase [VLCAD] protein) vector constructs that showed proof-of-concept in VLCAD$^{-/-}$ mice up to 8 weeks post-dose. Here we present data for up to 24 weeks post-dose. VLCAD deficiency is a rare, autosomal-recessive disorder of fatty acid oxidation with an incidence rate from 1:40,000 to 1:120,000 (about 50-100 babies born per year in the US). Mutations in the *ACADVL* gene lead to reduced levels of VLCAD, an inner-mitochondrial membrane protein, which catalyzes the rate-limiting step in β-oxidation. The most severe form of VLCAD deficiency (i.e., early or neonatal-onset), generally presents with hypoketotic hypoglycemia, hepatomegaly, and cardiomyopathy that can be fatal if not diagnosed early. While dietary management with medium-chain triglyceride oils has proven beneficial in preventing some symptoms, the risk of metabolic decompensation remains throughout a patient's life, particularly during times of increased energy demand. Additional durability data show continued gene expression of AAV9-ACADVL in VLCAD-deficient mice for up to 24-weeks post-dose. VLCAD$^{-/-}$ mice were treated systemically with various doses of two lead AAV9-ACADVL constructs and subjected to a cold-fast challenge at Weeks 12 and 24. This disease-specific phenotype was assessed by monitoring the animal's ability to thermoregulate and maintain euglycemia after a fasting cold challenge. Similar to results observed at 8-weeks post dose, internal body temperatures of untreated VLCAD$^{-/-}$ mice dropped below 20^{o}C and animals were hypoglycemic, resulting in mice becoming lethargic and moribund. In contrast, WT mice and AAV9-ACADVL-treated VLCAD$^{-/-}$ mice were able to maintain body temperatures and euglycemia. VLCAD protein expression in target tissues (liver, cardiac muscle, and skeletal muscle) was verified with IHC staining, Western Blot analysis, vector copy numbers and mRNA expression. Overall, the results from this study demonstrate the long-term durability of an AAV-mediated gene therapy to correct key biochemical and phenotypic aspects of VLCAD deficiency.

1157 Non-Canonical Amino Acid Incorporation into AAV5 Capsid Enhances Lung Transduction in Mice

Hao Chang*, Ailing Du*, Lingzhi Ren, Nan Liu, Xuntao Zhou, Guangping Gao#, Dan Wang#

Horae Gene Therapy Center, University of Massachusetts Chan Medical School, Worcester, MA

Although recombinant adeno-associated virus (rAAV) is the leading in vivo delivery vehicle for gene therapy, efficient transduction of certain tissues, such as the lung, remains a challenge. Novel AAV capsids usually carry peptide substitutions and/or insertions that comprise genetically encoded natural amino acids. In this study, we utilized genetic code expansion to incorporate Nε-2-azideoethyloxycarbonyl-L-lysine (NAEK), a non-canonical amino acid (ncAA), into the variable regions (VRs) of AAV5 capsid, and found that NAEK-modified rAAV5 exhibited enhanced lung tropism in mice. First, we incorporated NAEK into the AAV5 capsid at individual sites using an orthogonal suppressor tRNA system. Five rAAV5.NAEK mutants packaging the same EGFP transgene cassette were purified and evaluated for tissue tropism in adult mice via tail vein delivery. Our pilot experiment showed that one rAAV5.NAEK mutant exhibited 2-fold higher lung transduction than rAAV5, whereas liver, heart, and skeletal muscle transduction was comparable. The enhanced lung tropism of rAAV5.NAEK was also observed following intranasal (IN) administration. Following IN delivery, immunostaining of lung sections and Western blot of tissue lysates revealed that the rAAV5.NAEK mutant showed lung transduction that was 4-folder higher than rAAV5, 12-fold higher than rAAV6, and 9-fold higher than rAAV6.2FF. Alveolar type II cells were the main targets of both rAAV5 and the NAEK mutant as demonstrated by immunofluorescence staining, attributing the enhanced transduction to higher transgene expression rather than altered cell type specificity. Furthermore, in vitro assays using A549 cells, a human lung epithelial cell line, corroborated the enhanced lung transduction in mice, and demonstrated that cell binding and internalization of the rAAV5.NAEK mutant were significantly more efficient than rAAV5. Finally, we performed structural modeling of the NAEK-modified AAV5 capsid. Interestingly, we found that the long side chain of NAEK possibly impacted on a neighboring VR near the three-fold axis, a core area of capsid-receptor interaction, indicating that a synergistic structural change involving multiple VRs may contribute to the enhanced lung tropism. Recent advances in genetic code expansion allow for translational incorporation of an increasing number of ncAAs that possess diverse biological properties. Our study

suggested that ncAA incorporation into AAV capsid may confer novel vector properties, opening a new and complementary avenue for rAAV discovery. (*Co-first authors; #Co-corresponding authors)

1158 AAV Promoters for Ectopic Gene Expression in Absence of Rep or Viral Helper Factors

Sofia Fernandes, Joana Diogo, Júlia Guerra, Ana Sofia Cororadinha

ACTU, IBET, Oeiras, Portugal

Adeno-associated virus type 2 (AAV2) has three promoters to control viral expression: p5, p19 and p40. Several studies suggest a mechanisms of transactivation of AAV promoters by Rep proteins. In the absence of helper Adenovirus (AdV), Rep cooperates with cellular proteins to inhibit AAV promoters' transcription, repressing its own synthesis, through p5. After AdV infection, Rep promotes a cascade of reactions that activates promoters p19 and p40, inducing the synthesis of Rep and capsid proteins, respectively. Presumably, this activation is dependent on Rep ability to form complexes with other proteins inducing a DNA structural distortion at AAV promoters proximate[1]. The potential and strength of each AAV promoter to drive the expression of ectopic genes in mammalian cells, in the absence of Rep or helper factors, is not completely known. This works aims at further elucidating it and pave the way for their manipulation. In this work, to study independent AAV promoter activity, we developed several constructs containing AAV2 promoter p5, p19 or p40, driving the expression of reporter gene, *eGFP* or *Gluc* (*Gaussia luciferase*). Two different promoter sequences were tested to detect the minimal active region. The mammalian 293 cells and non E1-coding region cell lines, such as A549 and Vero, were transiently transfected. Promoter strength was measured by flow cytometry (FC) for GFP or by luminometer for Gluc, and compared to a mock control. In contrast to previous reports[2], two days after transfection, we observe constitutive GFP expression in all cells evaluated and from all AAV promoters. Promoters p5 and p40 shown the highest sactivity. Promoter p19, was reproducibly the weakest promoter. These data, show that AAV promoters can be used to drive constitutive expression of non-AAV genes, with different strengths, independently of Rep, adenoviral genes, or cell origin (human or monkey). We have found that the addition of an intron region, downstream p40 promoter decreased gene expression in both tested cells. A minimal region of less than 160 bp, for promoter p5 and p40 presented similar strength to cellular promoter hPGK. Additionally, we observed that in the presence of adenoviral helper factors (i.e E2A, E4 and VARNA) AAV promoters and cellular hPGK promoter presented higher activity. AAV promoter conformations with inducible potential are being tested. These results provide insights on how to design optimal expression cassettes, that can be of major importance in the development of an AAV cell-based platform production systems, devoid of helper AdV. **References:** 1- doi: 10.1128/jvi.76.16.8225-8235.2002. / 2- doi: 10.1128/JVI.00387-0

1159 Preclinical Proof-of-Concept of AMT-260, a Novel AAV9-Dual microRNA-Based Vector Targeting GRIK2 for the Treatment of Temporal Lobe Epilepsy

Nick Pearson[1], Stephane Baudouin[2], Morgane Wartel[3], Sonay Keskin[4], Andrew C. Mercer[5], Olivier F. Danos[6], Chrsitophe Mulle[7], Nicolas Partouche[8], Valerie Crepel[8]

[1]Toxicology & Translational Safety, uniQure, Basel, Switzerland,[2]Research, uniQure, Basel, Switzerland,[3]UniQure BV, Amsterdam, Netherlands,[4]Research, uniQure BV, Amsterdam, Netherlands,[5]REGENXBIO Inc., Rockville, MD,[6]REGENXBIO2, Rockville, MD,[7]CNRS, , Interdisciplinary Institute for Neuroscience, University of Bordeaux, Bordeaux, France,[8]INSERM, INMED, Aix-Marseille University, Marseille, France

The objective of this study was to demonstrate that lowering of the expression of the Glutamate Ionotropic Receptor Kainate Type Subunit 2 (GluK2) using RNA interference against its mRNA GRIK2 can be a therapeutic strategy for temporal lobe epilepsy (TLE). TLE is the most common form of focal epilepsy characterized by recurrent seizures generated in the hippocampus. Patients with TLE are often resistant to anti-seizure medications. Mossy fiber sprouting from dentate granule cells (DGCs) is a consistent anatomical hallmark of TLE, leading to synaptic reorganization in an aberrant excitatory network. In TLE, the DGCs operate via aberrant ectopic expression of GluK2/GluK5 receptors and GluK2/GluK5 was demonstrated to play a central role in the generation of seizure activity. However, the pharmacological potential of GluK2/GluK5 as a target for the treatment of TLE remained to be tested. The work presented here reveals the preclinical efficacy and safety of an AAV9 based vector, AMT-260, to knockdown GluK2 expression level. AMT-260 is an AAV9-vector carrying two microRNAs under the control of a neuron-specific human synapsin 1 promotor targeting GRIK2. The vector was tested in the pilocarpine mouse model for TLE and using hippocampal organotypic slices from patients with TLE. Injection of increasing doses of AMT-260 in the hippocampus of mice treated with pilocarpine showed a dose-dependent decrease in the number of electrical seizures per day, reduced hyperlocomotion and improved health. A full biological effect was observed at 5.0E+09 gc per hippocampus in pilocarpine mice. Efficacy was also observed in organotypic slices from patients with TLE treated with AMT-260 with a decrease in the number of electrical seizures recorded. The safety and biodistribution of AMT-260 was assessed in exploratory and GLP NHP studies after 1 and 3 months of treatment following convection enhanced, MRI guided intrahippocampal delivery of AMT-260, similar to the route proposed for clinical administration. At doses ranging from 6E+10 to 1.2E+12 gc/hippocampus of AMT-260, vector DNA was concentrated in the hippocampus and adjacent entorhinal cortex but orders of magnitude less in other brain regions and no or negligible peripheral exposure. High neuronal expression of the microRNA in the hippocampus was associated with substantial knockdown of GRIK2 mRNA (up to 90%) and GluK2 protein. No adverse findings were reported in the NHP. With the preclinical efficacy in TLE and a good safety profile, AMT-260 will proceed into clinical testing for the treatment of patients with refractory mesial temporal lobe epilepsy.

1160 Data Compilation and Novel Methods for Convection-Enhanced Delivery Using a SmartFlow® Cannula for Gene Therapy Products to the Nervous System of Large Animals

Zachary Carr, Stephanie Korszen, Emmett Kearney, Geary Smith, Cameron Wells, Jeremy Stigall, Ernesto Salegio

ClearPoint Neuro, Inc., Solana Beach, CA

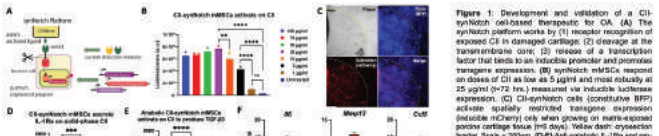
Accurate delivery of therapeutics into the central nervous system (CNS), brain and/or spinal cord is associated with a range of challenges. Implementation of imaging tools such as real-time magnetic resonance imaging (MRI) has led to the development of improved delivery protocols critical in preclinical and clinical studies. For this presentation, we have compiled data to demonstrate accuracy, effectiveness, and safety of delivering gene therapy vectors using the SmartFlow MR Neuro Ventricular Cannula. Data obtained from multiple studies conducted on more than N=50 nonhuman primates receiving intra-cranial infusions will be presented to demonstrate neurosurgical trajectory, positioning of the cannula within the selected anatomical structure, visualization/distribution/expression of the gene therapy product, histological analysis and post-surgical outcomes. In addition, as part of this presentation, novel data will be presented to showcase implementation and applicability of this technology in performing intra-spinal delivery, as well as intra-peripheral organ infusions using Omnipaque as the contrast agent. Approaches detailed herein will provide novel methods for the delivery of therapeutics within the brain, spinal cord, and peripheral organs, which are important considerations when targeting neurological disorders with a central and peripheral component.

1161 Synthetic Receptors Enable Regenerative Engineering for the Treatment of Osteoarthritis

Bonnie L. Walton[1], Victoria W. Tung[1], David D. Brand[2], Karen A. Hasty[2], Craig L. Duvall[1], Jonathan M. Brunger[1]

[1]Vanderbilt University, Nashville, TN,[2]University of Tennessee Health Science Center, Memphis, TN

Introduction: Osteoarthritis (OA) is a joint disease that affects over 32 million Americans, leading to pain and limited mobility. Cartilage catabolism, which exposes a collagen II (CII)-rich extracellular matrix, is one biophysical hallmark of OA brought about by several factors including inflammation from cytokines such as IL-1. Treatment of the disease is either palliative or involves surgical intervention; there are no clinically approved disease-modifying OA drugs. Current applications of cell engineering strategies to treat OA rely on unregulated expression of therapeutic transgenes and thus do not govern behaviors based on OA-specific pathology. Here, we present a cell design strategy using the synthetic Notch (synNotch) receptor platform. SynNotch is based on native Notch signaling, which requires an immobilized ligand for receptor activation. By engineering a synNotch extracellular domain (ECD) to recognize exposed CII, as well as an intracellular domain (ICD) to regulate transgene expression, cells can recognize OA pathology and perform regenerative functions to ameliorate the arthritic environment. **Methods:** We licensed cells to recognize degraded cartilage by engineering an OA-specific synNotch ECD via an scFv for a monoclonal antibody targeting CII (mAbCII). A synthetic transcription factor served as the ICD (**Fig. 1A**). Lentiviral vectors encoding the receptor and inducible payload transgenes were used to transduce CII-synNotch mouse mesenchymal stromal cells (CII-synNotch MSCs) with gene circuit elements. For solid-phase CII experiments, CII was passively adsorbed to culture vessels overnight. For porcine cartilage experiments, explants were cryosectioned and seeded with CII-synNotch MSCs. Luminescence was measured with a luciferase assay. Protein concentrations were determined via ELISA. 0.1 ng/ml IL-1 was used to upregulate inflammatory gene expression of ATDC5 mouse chondrocytes. Gene expression was assessed via qRT-PCR. **Results:** CII-synNotch MSCs achieve robust activation on 25 µg/ml solid-phase CII (**Fig. 1B**). Engineered cells expressing inducible mCherry on matrix-exposed cartilage explants reveal spatial regulation of the gene circuit (**Fig. 1C**), proving that a mAbCII-derived synNotch receptor enables activation only in the context of an OA-specific biomarker. CII-synNotch MSCs also programmably secrete anti-inflammatory IL-1 receptor antagonist (IL-1Ra) and pro-anabolic TGFβ-3 **(Fig. 1D-E)**, achieving versatility in therapeutic function. To assess synNotch function in the context of inflammatory signaling, CII-synNotch MSCs engineered to inducibly express IL-1Ra were plated on CII and co-cultured with IL-1-dosed mouse chondrocytes. IL-1Ra-producing MSCs antagonized inflammation in a CII-dependent manner (**Fig. 1F**). Modulation of gene expression illustrates the utility of engineered cells at detecting and combating OA-associated pathology. **Conclusions:** Using CII as an OA biomarker for synNotch transgene expression enables cells to be functional detectors of arthropathies and serve as living therapies. The regulation conferred by CII-synNotch MSCs may circumvent off-target effects of biologic drugs by restricting expression to niches displaying direct signatures of OA pathology. This work demonstrates enhanced cell engineering for musculoskeletal therapies and can be extended to include expression of other biologic drugs that may aid in the mitigation of OA.



1162 Genome-Wide Analysis of Triple-Play Plasmid Integration in Pinnacle PCL™ Producer Cells Lines across Multiple Recombinant AAV Programs

Nicholas J. Richards, Laurie Tran, Alix Eastham, Samuel C. Wadsworth, K. Reed Clark, Matthew Fuller

Ultragenyx Pharmaceutical, Cambridge, MA

We have developed a producer cell line (PCL) manufacturing platform (Pinnacle PCL) for production of recombinant AAV (rAAV) gene therapy products, which has demonstrated scalable 2000L production in an industrial setting to support ongoing Phase 1/2 and planned Phase 3 clinical trials. PCL generation is initiated via transfection of a single "triple-play" plasmid (pTP) containing the AAV rep-cap genes, a rAAV

transgene cassette flanked by AAV ITRs and an antibiotic resistance gene, followed by application of selective pressure to isolate stably integrated cells. Stable integrants are isolated, single-cell seeded via Verified In-Situ Plate Seeding (VIPS) and monitored for monoclonality with cell imaging analysis during outgrowth. Top clones, and rAAV generated from these top clones, are analyzed for desired phenotypic and genotypic qualities via program-specific and program-agnostic assays. Here, utilizing targeted locus amplification (TLA), we present genome-wide analysis of pTP integration in Pinnacle PCL clones from 6 gene therapy programs utilizing 4 AAV serotype capsids. TLA selectively amplifies DNA, both genomic and episomal, that is spatially proximal and can be crosslinked, which is then coupled with Illumina short-read next-generation sequencing to detect integrated pTP sequences and mapped to the point of insertion into the HeLa producer cell line genome. Interestingly, most pTP integration occurs within chromosome 19, averaging ~66% for all generated clones. Given the significantly higher level of integration at chromosome 19 than other genomic regions, especially when compared to predicted rates of random integration, we speculate that transient, low-level Rep 78/68 expression from the pTP during transfection is sufficient to drive this phenomenon. Importantly, integrated genome copy (IGC) assays were completed with 3 separate pTP ddPCR targets to verify the integration and copy number of pTP integrants in these Pinnacle PCL clones. Finally, a critical aspect of Pinnacle PCL development and characterization is the completion of a 16-week stability study, which is designed to determine if top clones demonstrate the phenotypic and genotypic stability required for 2000L manufacturing campaigns. TLA analysis of monoclonal PCLs generated for 4 gene therapy programs harvested at early and late time points in the 16-week stability study demonstrated genotypic, as well as phenotypic stability.

1163 Adeno-Associated Virus (AAV) Loaded Hydrogel Implants Improve GFP Expression and Reduce Anti-Drug Antibody Titers (ADA) and Ocular Inflammation in Rabbits

Meryem Pehlivaner, Steven Lu, Nelson Bello, Rabia Gurses-Ozden, Rami El-Hayek, Charles Blizzard, Michael H. Goldstein, Peter K. Jarrett

Ocular Therapeutix, Bedford, MA

Purpose: Intravitreal (IVT) dosing of AAVs often induces an inflammatory response that increases with dose. In this study, we tested how the pharmacokinetics of AAV delivery via a degradable hydrogel implant can impact ocular inflammation, immune response, and transgene expression. **Methods:** We prepared AAV2.7m8-CMV-GFP loaded hydrogel implants at a dose of 3.6E+10 GC/implant to release AAVs over 4 (Fast Release) or 14 days (Medium Release). A single implant was injected intravitreally in both eyes of New Zealand White rabbits. Bilateral injections of a bolus 50µL AAV solution at the same dose were performed as a positive control. Inflammation in rabbit eyes was assessed via ocular examinations (n=3 rabbits/6 eyes per group). Green fluorescent protein (GFP) expression was evaluated through fundus autofluorescence (FAF) imaging (n=3 rabbits/6 eyes per group) and enzyme-linked immunoassay (ELISA) quantification in ocular tissues (n=3 rabbits/3 eyes per group). Vector copies in rabbit plasma were detected by quantitative polymerase chain reaction (qPCR) and ADA titers in serum were determined by ELISA. **Results:** The greatest amount of GFP was expressed in rabbit ocular tissues with the medium release AAV group (Figure 1). Ocular examinations and ELISA test results showed the Medium release group had lower peak inflammation at Week 3 and lower ADA titer levels at Week 13 compared to the other groups (Figure 2A & 2B). Modulating release kinetics of AAVs via hydrogel implants can also reduce systemic levels of AAV as evidenced by lower copy numbers from the AAV implant groups in plasma (Figure 2C). **Conclusions:** In this study, we show that instead of bolus injection, delivering a high dose of adeno-associated virus (AAV) over time using a sustained-release modality could reduce inflammation, lower ADA titers in serum, and improve transgene protein expression. These data demonstrate that controlled release AAV implants may provide a therapeutic benefit for ocular gene therapy.

Figure 1. Quantification of GFP in rabbit ocular tissues via ELISA and representative Week 12 FAF images.

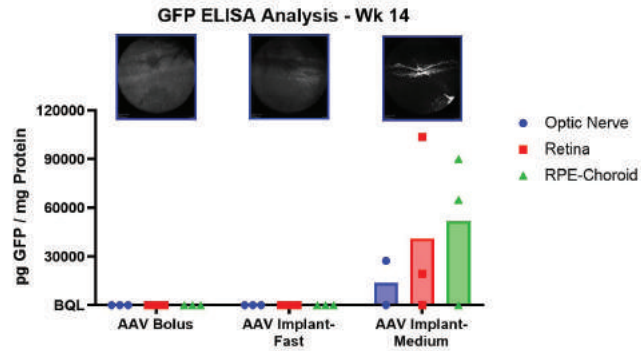


Figure 2. Effect of controlled release of AAVs on (A) inflammation-aqueous cells, (B) ADA titers, and (C) vector shedding.

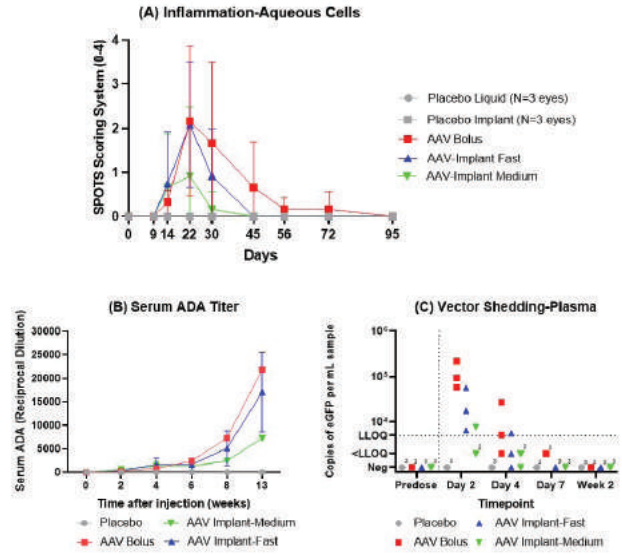

1164 A Functionally Enhanced Tumor-Infiltrating Lymphocytes Product (GT201) Exhibits Improved Persistence and Anti-Tumor Efficacy with Low IL-2 Dependency

Jingwei Sun, Jiahui Jin, Quanwei Wang, Yiyang Tan, Pin Wang, Jingman Wang, Yongchao Tan, Zhao Xu, Lingyun Chen, Yarong Liu

Grit Biotechnology, Shanghai, China

Adoptive cell therapy by tumor-infiltrating lymphocytes (TIL) has demonstrated promising clinical benefits for patients with late-stage solid tumors. However, high-dose IL-2 used as standard adjuvant for TIL therapy requires close clinical monitoring and may cause toxicities. Furthermore, the prone-to-exhaustion status of final TIL product after rapid expansion in vitro as well as the immunosuppressive tumor microenvironment further limits the persistence and efficacy of TIL post infusion into patients. Grit Biotechnology designed a genetically engineered TIL product (GT201) to express a membrane-bound cytokine that is critical for T cell survival and function. Different liker designs of GT201 were examined and the best design was selected based on stable expression of GT201 construct on T cell surface and increased cis and trans signaling, therefore enhanced functional impact on TIL. GT201 showed significantly improved long-term survival and preservation of TCR clonality without IL-2 in vitro, as well as persisted longer in multiple tissues without IL-2 than conventional TIL + IL-2 in NOG mice. In the meanwhile, anti-tumor function was also significantly enhanced in GT201 as demonstrated by increased cytotoxicity and cytokine production against tumor cells in vitro and better tumor control ability during serial killing assays. Notably, GT201 TIL achieved better anti-tumor efficacy with low IL-2 than conventional TIL with normal IL-2 in a PDX mouse model treated with autologous TIL, corelated with higher IFN-γ release in mouse serum. Further mechanistic studies demonstrated that GT201 mainly act through cis signaling, but GT201 transduced TIL would not survive over two months without IL-2 in culture. If working by trans signaling, it would preferentially modulate activated T cells and NK cells, for instance, tumor reactive immune subsets in the cancer setting, rather than their naive counterparts, suggesting a low possibility of over-activation of immunity. Taken together, GT201 demonstrated enhanced persistence and anti-tumor efficacy with low IL-2 dependency in vitro and in vivo. Currently, manufacturing process of GT201 TIL product has been successfully developed (StaViral®), and clinical assessment of GT201 as a next-generation TIL therapy is ongoing in an investigator-initiated trial in China.

1165 Discovery of Novel AAV Capsids with Enhanced Skeletal Muscle Tropism Following Directed Evolution in Cynomolgus Macaque

Quan Jin, Ka Ying Sharon Hung, Samneet Kashyap, Emily Rouse, Margaret Kelemen, Lucia Xiang, Aditya Utturkar, Misha Chittoda, Harini Sampath, Shawn Bourque, Samantha Desmarais, Shuyun Deng, Wei Tong Chen, Davide Gianni, Junghae Suh, Yuan Yuan

Gene Therapy Accelerator Unit, Biogen, Cambridge, MA

The application of recombinant AAV vectors for therapeutic gene delivery holds substantial promise in the treatment of musculoskeletal and neuromuscular disorders. However, sufficient muscle targeting by existing AAV vectors in humans necessitates high systemic doses, which have been associated with adverse events across several clinical trials. Thus, there is a need to identify novel vectors with enhanced muscle targeting, which may improve gene delivery efficiency and allow lower doses to be used. Here, we report the discovery of a set of skeletal muscle-tropic AAV capsid variants in cynomolgus macaque. Prior engineering efforts have suggested that incorporation of an integrin-binding Arg-Gly-Asp (RGD) motif on the AAV capsid surface may enable redirection of vectors to integrin heterodimers. To investigate whether RGD motif-displaying AAV capsids can be effectively retargeted, we inserted a 7-mer peptide containing an embedded RGD motif in variable region VIII (VR-VIII). To construct the plasmid library, capsid-coding sequences were placed between the AAV inverted terminal repeats (ITRs) so that each produced capsid would package its own originating genome. This AAV library was iteratively screened via intravenous administration in cynomolgus macaques, and skeletal muscle-recovered capsid cDNA was cloned back into the library backbone for subsequent rounds of screening. In parallel, we monitored capsid variant abundance at each screening stage of directed evolution through short-read sequencing. We observed significant enhancement in skeletal muscle transduction by Round 2 compared to Round 1 AAV library, suggesting positive selection on muscle-targeting variants. From the sequencing analysis, we identified a set of RGD motif-displaying capsids with enhanced transduction in skeletal muscle, with top variants demonstrating over 20-fold enhancement compared to benchmark. Further sequence analysis uncovered distinct peptide motifs that exhibited consistent enrichment. Additional comparative analysis on liver and DRG transduction confirmed that enrichment of these novel variants was generally more specific to skeletal muscle. Presently, further characterization of these capsids is in progress, and validation studies are underway.

1166 Production of AAV Vectors in a Scale-X™ Fixed-Bed Bioreactor

Hyowoo Lee[1], Youngbin Park[2], Hong Kee Kim[2], Changmin Kang[2], Haeshin Lee[2], Jae-Hyung Jang[2]

[1]Yonsei University, Seodaemun-gu, Seoul, Korea, Republic of,[2]Glugene Therapeutics Inc., Daejeon, Korea, Republic of

The adeno-associated viral (AAV) vector has emerged as a viable option for many gene therapy applications due to its low immunogenicity, broad tissue specificity, and long-term transgene expression. To meet the growing demand for large quantities of AAV required for clinical trials and treatment, a scalable production technology of AAV vectors

is needed. Fixed-bed bioreactors offer an advantage in the production of AAV vectors by providing a large-scale and controllable platform equally suitable for both adherent and suspension cells. scale-X™, a commercialized fixed-bed bioreactor from Univercells Technologies, has a large surface area based on a spiral-wound double-layer structure similar to 2D cell culture environment. Therefore, we aimed to develop large-scale AAV production using the scale-X hydro bioreactor. As a first approach, we applied the production parameters from our lab-scale production system. The viral productivity of our first bioreactor run did not reach our expectations due to low transfection efficiency and cell death caused by the toxicity of calcium phosphate. We then developed a polyethylenimine (PEI)-based transfection method, focusing on the DNA amount and PEI:DNA ratio. We also added a rinsing technique after transfection to reduce residual transfection agent effects. The scale-X hydro bioreactor, with a 2.4m^2 surface area, showed similar viral productivity per area as the 2D lab-scale system. We also compared the infectivity of AAV produced by the bioreactor and cell culture plates. Flow cytometry results demonstrated that the scale-X bioreactor could produce AAV vectors with high infectivity compared to the 2D lab-scale system. In addition, The scale-X nitro (600m^2), a further compatible scalable option provided by Univercells Technologies, will meet the requirements for large-scale clinical trials.

1167 Chunk Editing: A Novel Method to Extend the HDR "Rewriting" Window from 10 to 1000s of Base Pairs

Christopher Piggott, Laurentia Tjang, Selina Chen, Emma McIntyre, Utsav Tatu, Antonina Jaroszweska, Jocelin Chen, Hannah Hirou, Joelle Faybishenko, Richard Gavan, Chris Hackley

CRISP-HR Therapeutics, San Carlos, CA

CRISPR enabled cell and gene therapies have the potential to revolutionize the field of genetic medicine. However, the vast majority of rare diseases remain untreatable due to the limitations of current tools and techniques. To date, most non knockout (KO) based therapeutics have been restricted to mutation-by-mutation approaches, where either HDR, or newer techniques (base/prime editors), rewrite small regions of DNA at a time (~1-100 bp). While these approaches are powerful, short editing windows (relative to the size of human genes) are financially and/or technically incompatible with most rare-disease mutation profiles. Here, we demonstrate for the first time that CRISPR/Cas9 can be used to "rewrite" 4kb+ sections of the human genome simultaneously via a selection-free process we have named "chunk editing". In these experiments, H1299 and HEK293 cells were transfected with plasmids that encoded guides, nuclease, and DNA donor repair template using lipofectamine 3000. Three days post transfection, cells were lysed and genomic DNA was extracted, amplified, and prepared for sequencing on either Illumina MiSeq or NextSeq sequencers. Standard tools were used to filter and align the resulting sequencing data which was then quantified via custom code. Our first target was exon 14 of Factor 8, a therapeutically relevant target with over 65 individual mutations classified as likely-pathogenic or pathogenic in NCBI's ClinVar database. H1299 cells were transfected as above, with the repair template containing 12 introduced SNPs scattered throughout the ~3.3kb editing window. Using our novel chunk editing techniques, we achieved remarkably consistent editing rates (~2-3% of total reads sequenced) across the entire editing window of exon 14 (Fig 1A, blue line) with two controls (transfected without guide and untransfected; dashed blue and black lines respectively) showing minimal background levels of editing (<0.1%). To determine whether this chunk editing strategy is necessary to allow for long-range editing, we assayed another locus, exons 6-8 of the PAH gene, introducing 7 SNPs over an almost ~4kb editing window. As expected, traditional HDR approaches (purple) showed a marked drop in efficiency outside of the expected ~10bp window (from 0.6% to <0.1%), whereas chunk editing (blue) showed a much more even editing profile (0.4-0.6%) throughout the whole editing window. Chunk editing in HEK293 cells showed remarkably similar results (0.6-0.8%), demonstrating that this technique can be used in multiple cell types and genomic loci. While future work remains to explore and optimize chunk editing strategies, we believe the ability to extend HDR based editing windows to thousands of base-pairs will have a tremendous impact on future therapeutic and R&D applications.

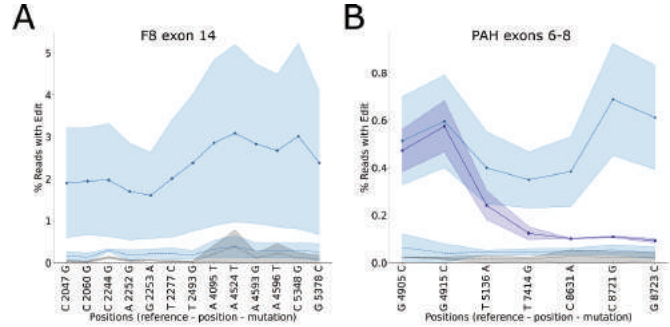

Figure 1 Legend: **1A**: Graph showing editing rates across 3kb+ of genomic DNA using chunk editing strategy. nuclease, guides, and repair template (RT) in blue; nuclease and RT (no guides) dashed blue; untransfected control in dashed, black. Shading shows the Standard Error of the Mean (SEM) for each treatment, n=3 per treatment. **1B**: Graph showing editing rate for legacy approach (purple) or chunk approach (light blue, solid line), with controls pattern as in 1A. Shading shows the Standard Error of the Mean (SEM) for each treatment, n=3 per treatment.

1168 Self-Adjuvating Lipid Nanoparticle mRNA Vaccine Elicits T-Cell Responses and Protects Against Immune Challenge

Syed Reza

Drug Delivery Sciences, NOF Corporation, White Plains, NY

BACKGROUND: Nucleic acid vaccines, DNA and messenger RNA (mRNA), have emerged as promising modalities for infectious disease and for cancer immunotherapy due, in part, to shortened manufacturing cycles and high potency. Currently, there is limited understanding of the mechanisms of antigen presentation and induction of specific T-Cell responses critical to long-term immunity. Lipid nanoparticles (LNP) composed of ionizable lipids are important components of such vaccines as they can convey and present the nucleic acid effectively to the immune system. Further improvements in LNP carriers require a reduction in the 1) systemic toxicity, 2) improved endosomal escape, 3) potent and T-cell specific adjuvating function and 4) targeting to specific antigen presenting cells. RESULTS: Previously we have reported that lipid nanoparticles

composed of a novel ionizable, biodegradable lipid ("SS-Lipid") can deliver pDNA or mRNA in mice to liver, solid tumors, and other organs via the IV route and achieve high levels of expression. We also evaluated the safety of the lipids in mice where total lipid doses of up to 175 mg/kg were well tolerated. We next evaluated the delivery of DNA and RNA vaccines via the SC route. Multiple SS-Lipid derivatives were synthesized and identified one lipid (SS-EC) that specifically activated macrophage cell in vitro. Antibody generation response was assessed in BALB/c mice with SS-EC 1.5x μg OVA mRNA injected 3X at weekly intervals and compared with immunization with OVA protein+polyI:C. SS-EC LNP produced a 2.2X higher titer compared with OVA-polyI:C control (Figure 1A). To assess induction of cytotoxic t-cell activity, SS-EC-LNP carrying OVA-encoding mRNA or Luciferase-encoding mRNA were administered at a dose of 0.05 μg of mRNA. The CTL percent lysis activity at 1 week was 75% (SS-EC_OVA-mRNA) of pulsed antigen cells. Sufficient CTL activity was not obtained with other DOTAP liposome, SS-EC_Luc-mRNA and empty LNP (Figure 1B). We then evaluated if robust CTL responses could demonstrate activity against solid tumors. Mice were injected with OVA expressing E.G7 cells as a model for disseminated malignant disease, and treated with SS-EC LNP OVA-mRNA (0.2 μg) after 10 days or SS-EC Luc mRNA as negative control. Tumor growth was significantly repressed in the test animals with negligible growth by day 25 (Figure 2). Additional data on the development of a room temperature stable formulation of SS-Lipid mRNA drug producct will be presented. CONCLUSION: We here demonstrate that a novel ionizable lipid SS-E and SS-EC specifically activates macrophages in vivo and this response is correlated with antibody expression and Cytotoxic T-Cell activity. T-Cell responses were shown to be effective in limiting growth of tumor cells in a disseminated disease model. Further efforts are needed to optimize the dosage and formulation towards achieving a single dose vaccine product. These findings suggest LNP composed of SS-E and SS-EC can be effective delivery systems for DNA and RNA vaccines.

1169 Optimization of a Versatile Downstream Process for Multiple Novel AAV Capsids That Demonstrates Improved Recovery

Sophia Petraki, Leandro Fernandez, Amit Mirchandani, Abagail Wells, Hari Acharya, Heidy Morales, Elissa Troisi, Jesse Granados, Emily Springfield

Capsida Biotherapeutics, Inc., Thousand Oaks, CA

The gene therapy field has seen a surge in treatment candidates using recombinant adeno-associated viruses (rAAVs). The field is exploring novel capsids, derived from wildtype serotypes, to achieve more efficient gene delivery. While novel capsids are more efficient delivery vehicles, they may perform unexpectedly in purification platforms established with wildtype serotypes. Additionally, novel capsids may yield higher titers and have characteristics (e.g., charge, percent full, etc.) impacting compatibility with pre-defined buffers and the sizing of process components. Adapting downstream steps is crucial for the successful development of a manufacturing-scale process. Through a series of screening experiments at different scales with two commercially available resins and a range of buffer formulations, a toolkit of buffers specific to AAV affinity-based chromatography was developed. Affinity step recovery for multiple novel capsids was improved 30-50% through this optimization process. Recoveries in line with wildtype serotypes were achieved. In addition to optimization of the affinity capture step, recovery was improved by 20% and 60% through optimization of ultrafiltration parameters and filtration sizing, respectively. These optimizations were performed at bench scale and subsequently confirmed at larger development scales. Through process optimization and parameter screening a robust purification process was developed for multiple novel capsids.

1170 AAV-Mediated Gene Augmentation Therapy of *CRB1* Patient-Derived Retinal Organoids Restores the Histological and Transcriptional Retinal Phenotype

Xuefei Lu, Nanda Boon, Charlotte A. Andriessen, Jan Wijnholds

Ophthalmology, Leiden University Medical Center, Leiden, Netherlands

Background: Mutations in both alleles of the Crumbs homologue 1 (*CRB1*) gene mostly cause retinitis pigmentosa (RP) and Leber congenital amaurosis (LCA), whereas some mutations cause macular dystrophy. CRB1 and CRB2 are family members and large transmembrane proteins consisting of a short 37 amino acid intracellular domain containing a conserved C-terminal glutamic acid-arginine-leucine-isoleucine (ERLI) PDZ binding motif and a protein 4.1, ezrin, radixin, moesin (FERM) motif juxtaposed to a single transmembrane domain, and a large extracellular domain with multiple laminin-A globular and epidermal growth factor (EGF) like domains. CRB1 and CRB2 proteins are required for organizing apical-basal polarity and adhesion between photoreceptors and Müller glial cells. CRB1 and CRB2 localize at the retinal outer limiting membrane at a subapical region adjacent to adherens junctions between Müller glial cells and photoreceptors. So far, no treatment possibilities are available for patients with RP or LCA caused by mutations in the *CRB1* gene. Previous studies in *Crb1* and *Crb2* knockout mice showed proof of concept for AAV2/9.CMV.h*CRB2*, but not AAV2/9.CMVmin.h*CRB1*,

transduced onto Müller glial cells and photoreceptors. Transduction of only Müller glial cells or only photoreceptors was not effective, whereas transduction of both cell types was. Here, we studied the effects of 4.8 kb AAV2/5.CMV.h*CRB2* and 4.8 kb AAV2/5.CMVmin.h*CRB1* gene augmentation vectors on multiple independent biological replicates of *CRB1* patient retinal organoids with c.3122T>C p.(Met1041Thr) homozygote missense mutations, or with 2983G>T p.(Glu995∗) and c.1892A>G, p.(Tyr631Cys) compound heterozygote mutations, or with c.2843G>A p.(Cys948Tyr) and c.3122T>C p.(Met1041Thr) compound heterozygote missense mutations. **Results:** *CRB1* patient-derived induced pluripotent stem cells were differentiated into *CRB1* retinal organoids. Surprisingly, the *CRB1* retinal organoids with missense mutations show a near complete loss of variant CRB1 protein at the outer limiting membrane by immunohistochemical analysis. Interestingly, the localization of the CRB2 protein or other CRB-interacting protein is not affected. Compared to isogenic controls, the *CRB1* patient organoids show moderate but significant loss of photoreceptors at differentiation day 210. Single cell RNA-sequencing (scRNAseq) of the *CRB1* patient and isogenic controls showed clustering of cells into Müller glial cells, stromal cells, mature rods, immature rods, cones, transient cell populations, bipolar cells, retinal pigment epithelial cells, proliferating cells, amacrine cells, astrocytes, horizontal cells and ganglion cells. ScRNAseq at differentiation day 230 revealed changes in the endosomal pathway and cell adhesion and migration in *CRB1* patient-derived retinal organoids compared to their corresponding isogenic controls. Adeno-associated viral serotype 5 (AAV2/5).CMV.*GFP* efficiently transduced Müller glial cells in addition to photoreceptors and retinal pigment epithelium at differentiation day 120, whereas (AAV2/2).CMV.GFP efficiently transduced photoreceptors and retinal pigment epithelium at differentiation day 120. AAV2/5.CMV.h*CRB2* or AAV2/5.CMVmin.h*CRB1* gene augmentation in Müller glial and photoreceptor cells partially restored the histological phenotype and transcriptomic profile of *CRB1* patient-derived retinal organoids as determined by scRNAseq. **Summary:** Altogether, we show proof-of-concept that AAV.h*CRB1* or AAV.h*CRB2* treatment improved the phenotype of cultured *CRB1* patient-derived retinal organoids, providing essential information for future gene therapy approaches for patients with mutations in the *CRB1* gene.

1171 Optimizing Adeno-Associated Virus-Based Gene Therapy for the Treatment of Surfactant Protein B Deficiency

Nicole Zielinska[1], Yanlong Pei[1], Brenna A. Y. Stevens[1], Elena S. B. Campbell[1], Madison E. Hughes[1], Melanie M. Goens[1], Dinghai Zheng[2], D. Benjamin Gordon[2], Raja R. Srinivas[2], Alec A. K. Nielsen[2], Jeff L. Caswell[1], Luis A. Castro[3], Sarah K. Wootton[1]

[1]Pathobiology, University of Guelph, Guelph, ON, Canada,[2]Asimov, Boston, MA,[3]Clinical Studies, Ontario Vetrinary College, Guelph, ON, Canada

Background: Surfactant protein B (SP-B) deficiency is an inherited disorder that leads to respiratory failure immediately after full-term birth. With the limited treatment options offering only transient improvement, this disease is lethal within the first year of life. Given that SP-B deficiency only affects the lungs, targeted delivery of gene therapy to the respiratory tract holds promise in treating this disease. With the proliferation of gene therapy clinical trials, safety and serious adverse events emerge as key considerations for drug product development. Many AAV gene therapies continue to use highly active promoters to drive the expression of therapeutic transgenes. Although these ubiquitous promoters are well-established and confer strong transgene expression, they continue to present disadvantages. A common problem observed is non-targeted transgene expression that can result in compromised cell health, inflammation, and toxicity. Our approach to address these safety concerns involves computational mining and engineering of lung specific promoters to drive gene expression in target tissue and prevent expression in off-target tissues that may cause adverse events or increase immunogenicity of the vector. Using our engineered AAV6.2FF vector expressing an alkaline phosphatase (AP) reporter gene under the control of 4 different putative lung specific promoters identified through computational screens, we evaluate targeted transgene expression in mice. **Methods:** AAV vectors were administered to C57BL/6 mice (n=4), with two additional control groups, one receiving 1xPBS as a negative control and the other receiving an AAV6.2FF vector expressing AP from the ubiquitous promoter CASI as a positive control. Mice were transduced with $1x10^{11}$ vector genomes (vg) intranasally, intramuscularly, and intraperitoneally to ensure targeting of all possible tissues. 21 days post-administration, mice were euthanized, and all major organs harvested and stained for AP reporter gene expression. Gross images of the tissues were taken, and AP activity assays were conducted to quantify the amount of AP protein per tissue. Histologic analysis will be performed to identify the various cell types where the promoters are active. **Results:** All but one of the promoters show efficient gene expression in the lung with minimal off target expression. AP assays confirmed low to undetectable AP expression in the brain, heart, liver, nasal cavity, pancreas, spleen, and trachea for all lung specific vectors. The positive control demonstrated strong transgene expression in many tissues outside of the lungs including the heart, liver, spleen, and muscle. Visually, lung transduction in the positive control and in 3 of the lung specific promoters appear to be very similar in magnitude (Fig. 1). **Conclusions:** The use of AAV6.2FF in conjunction with computationally predicted lung specific promoters can efficiently transduce the lungs while minimizing off target effects in the rest of the body. In addition to localizing transgene expression, lung specific promoters have the capacity to express just as effectively as well-established ubiquitous promoters thereby increasing the safety of AAV gene therapies for monogenic lung diseases like SPB-deficiency.

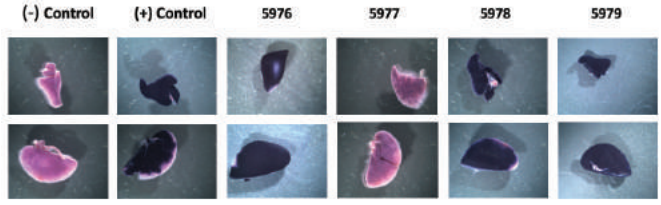

Fig 1. Human placental alkaline phosphatase expression in the lungs of C57BL/6 mice 21 days post AAV administration with various promoters identified through computational analysis.

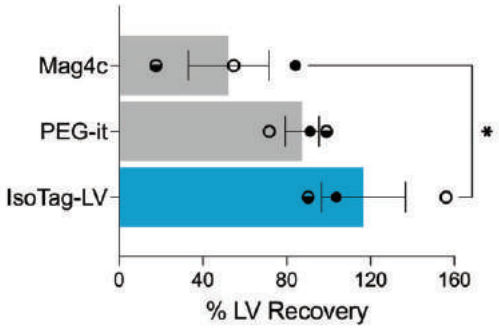
1172 IsoTag®LV - A Scalable, Chromatography-Free Solution to Lentiviral Purification Using a Novel Affinity-Based Platform

Michael Dzuricky
Isolere Bio, Durham, NC

The rapidly growing cell and gene therapy field has the potential to target a wide range of previously incurable diseases and cancers, due in no small part to the use of lentiviral vectors (LVs). LVs can target a variety of dividing and non-dividing cell types and can carry large genetic loads predominantly used for ex vivo transgene delivery. However, the fragility of LV envelopes, a critical component to their high potency, makes manufacturing difficult at each step of the production workflow. Anion exchange chromatography (AEX) and the many, complex downstream steps are the main contributors to low LV recovery due to long processing times and the requirement of harsh buffers. This leads to expanding upstream production volume, exponentially increasing the demand for expensive raw materials. These factors are a major reason why the costs of curative cell and gene therapies on the market and in clinical trials are so high. We developed a chromatography-free purification platform using our novel affinity reagent, IsoTag®LV, to streamline downstream purification into a two-step TFF process. The first step, a concentrate and wash of the crude harvest material, has a step recovery of over 90% and provides a two-log reduction of host cell proteins (HCP). The second step removes the IsoTag®LV reagent, providing highly pure LV with a step recovery of 60%. The entire process concentrates and purifies LV by 200X with a total functional recovery of over 50%. Improved recoveries are attributed to the use of gentle buffers as well as the inherent virus-stabilizing capabilities of IsoTag®LV. When mixed with LV, IsoTag®LV enhances viral stability to improve recoveries by over 50% in high salt, elevated temperature, and for an extended time at 4-8 °C. Furthermore, IsoTag™LV improved vector stability during freeze-thaw cycling and improved transduction efficiencies in T cells by 5x. The IsoTag®LV system is a revolutionary leap forward in LV downstream purification and successful implementation of this platform could significantly reduce the volumetric burden placed on lentiviral manufacturers and the cost burden placed on patients.



1173 AAV Capsid ELISA Automation for High-Throughput AAV Titer Determination

Dana Holzinger, Christina Sonnek, Katharina Hammer, Caroline Odenwald, Katja Betts
PROGEN Biotechnik GmbH, Heidelberg, Germany

Today, AAV-based gene therapy is one of the most promising and fastest growing branches of modern medicine. This development is reflected by the great influx of big pharma and new technologies into the field that could be observed over the last years. The fast growing environment allows a quick development due to the extensive investment; however, it also poses many challenges that need to be addressed. Among those is the competitive go-to-market time pressure as well as increasing numbers of samples that need to be processed and analyzed within the same time span. Consequently, there is a growing demand for more time-efficient solutions with less hands-on time for analytical characterization of AAV samples. Amongst the commercially available analytical tools, the AAV capsid ELISA is one of the most reliable and established methods for AAV total capsid titer quantification. To show that the AAV capsid ELISA is suitable for high-throughput processing, PROGEN has conducted a study. By transferring our established manual PROGEN AAV ELISA to a fully automated system, we have been able to show the potential for automation and high-throughput processing. This involved analyzing and validating the key performance indicators of our available AAV9 and AAV8 ELISAs (i.e. PRAAV9, PRAAV9XP, PRAAV8 and PRAAV8XP) using the fully automated system DSX from Dynex Technologies. The Dynex DSX is a fully automated 4-plate ELISA processing system, capable of performing several assays per plate simultaneously. This provides optimized efficiency and speed. Here, we show the data on homogeneity, intra- and inter-assay variance, as well as recovery obtained by the automated system compared to the same key performance indicators obtained by manual processing of the assays. The fully automated system has significantly reduced hands-on time, as well as higher sample throughput, whilst maintaining the benefits of the conventional AAV ELISA, i.e. robustness and accuracy in AAV titer determination. In conclusion, with this data we provide a high-throughput protocol for our AAV ELISA users who are analyzing high sample numbers per run and need to save time.

1174 Optimal Design of an AAV Vector is Critical to Evade Toxicity of Gene Therapy in a Mouse Model of Neuronopathic Gaucher Disease

Giulia Massaro, Amy Geard, Hemanth Nelvagal, Simon Waddington, Ahad A. Rahim
University College London, London, United Kingdom

Gaucher Disease (nGD) is an inherited metabolic disorder caused by mutations in the *GBA1* gene. It is the most common lysosomal storage disease and can manifest with severe neurodegeneration and visceral pathology. The most acute neuronopathic form (type 2, nGD), for which there are no curative therapeutic options, is characterised by devastating neuropathology and death during infancy. In this study, we investigated the therapeutic benefit of systemically delivered AAV9 vectors expressing the human *GBA1* gene at two different doses comparing a neuronal-selective promoter with the

ubiquitous chicken-β-actin promoter, on survival, neurodegeneration, motor function, biochemical markers, and visceral pathology. High dose gene therapy resulted in extended life span of knock-out mice, normalisation of neuropathological markers, behavioural indexes, and increased enzymatic activity in brain and visceral organs. While supraphysiological expression of glucosylcerebrosidase (GCase) was beneficial in ameliorating the neuropathology, signs of inflammation were present in the viscera of mice treated with the ubiquitous vectors, suggesting that elevated GCase expression may promote inflammation and have deleterious effects in the liver and other visceral organs.

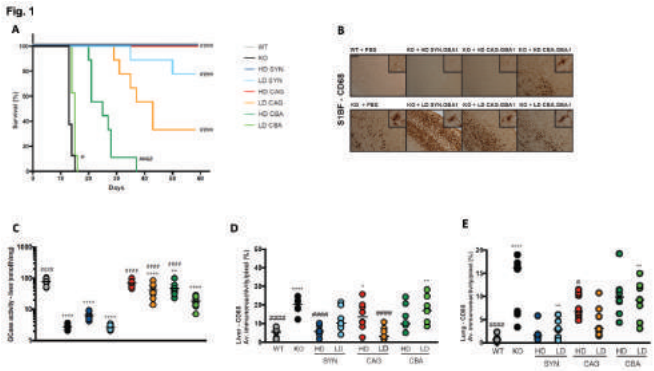


FIG. 1 Gene therapy rescues the K14-lnl/lnl model in a dose-dependent fashion and ameliorates neuropathology, while treatment with the ubiquitous vectors leads to increased inflammation in the viscera. ***A*** *Kaplan-Meier survival curve. Data expressed as percentage of survival. HD: high dose; LD: low dose.* ***B*** *Representative images of brain sections (cortical region S1BF) stained for the macrophagic marker CD68.* ***C*** *GCase enzymatic activity in liver homogenates.* ***D-E*** *Quantification of immunoreactivity of liver and lung sections stained for CD68. * indicates statistically significant difference between the experimental group and WT controls; # indicates statistically significant difference between the experimental group and untreated KO controls.*

We further evaluated the effect of sustained high-levels expression of GCase driven by the CAG promoter in a 1-year long-term study. Our long-term study showed that sustained GCase expression does not fully reverse the brain pathology, as demonstrated by the increased hyperactivity in the 1-year-old mice treated with CAG.hGBA. Our results highlight the importance of a careful evaluation of the promoter sequence used in gene delivery vectors, suggesting a neuron-targeted therapy leading to high levels of enzymatic activity in the brain but lower GCase expression in the viscera, might be the optimal therapeutic strategy for nGD.

Data expressed as percentage of survival. # indicates statistically significant difference between the experimental group and untreated KO controls.* ***B*** *Examples of open field traces and heat maps (total time spent in a specific position of the chamber during movement).* ***C*** *Distance travelled and mean speed travelled in the open field chamber in a 5-minute time period.*

1175 Development of SKG0106 Vector for the Effective, Safe and Durable Treatment of Neovascular Age-Related Macular Degeneration

Byron Li, Yanqun Shu, Qiongqiong Ren, Peilu Li, Huimin Kong, Lumei Xiao, Bing Wu, Sijia Huang, Jinxin Deng, Zheng Luo, Dianyang Chen, Jay Hou
Skyline Therapeutics, Cambridge, MA

Anti-VEGF therapies revolutionized the treatment of neovascular age-related macular degeneration (nAMD), yet real world evidence suggest that long-term outcomes decrease over time and treatment complication occurs due to the burden of frequent intravitreal (IVT) injection. Therefore, a long-lasting and effective treatment is badly needed by patients with the condition. SKG0106 is a novel recombinant AAV vector we developed for the treatment of nAMD via IVT administration. SKG0106 comprises a proprietary capsid and a transgene genome that encodes an anti-VEGF protein, Nb24. Upon delivery, SKG0106 transduces retinal cells, and the expressed Nb24 effectively and specifically suppresses the action of human VEGF, a key factor contributing to the pathological angiogenesis of nAMD in patients. A number of pharmacological studies were conducted to thoroughly evaluate the efficacy of SKG0106 using a DL-α-AAA induced rabbit model of chronic retinal neovascularization (RNV) and a laser photocoagulation induced monkey model of choroidal neovascularization (CNV). In all studies, SKG0106 was administered via a single IVT injection. At pre-determined time points, the efficacy of SKG0106 was quantified in the rabbit RNV model based on the improvement rate of fluorescein leakage area and evaluated in the monkey CNV model based on 1) grade 4 laser spot rate, 2) mean

fluorescein leakage area, and 3) thickness of subretinal hyperreflective material (SHRM). The local tolerance in eyes was assessed by slit lamp microscopy. In the DRF study with rabbit CNV model, multiple doses of SKG0106 were administered, and the study lasted for 6 weeks. The treatment at all dosage levels significantly reduced fluorescein leakage area and exhibited a sigmoidal dose-response curve. The vector from the dose of 1E9 vg/eye and above completely inhibited fluorescein leakage, comparable to that of Eylea®. In addition, SKG0106 inhibited fluorescein leakage until the end of the study, while Eylea® lost its activity. The results suggested that SKG0106 was effective and lasting in repressing the activity of VEGF. Besides, the vector was well tolerated. In the DRF study with monkey CNV model, 6 doses of SKG0106 were administered (4-8 eyes/group), and the study lasted for 6 weeks. SKG0106 exhibited a dose-dependent effect in reducing CNV grade 4 spot rate and mean spot leakage area at 1-2 weeks post-modeling, the thickness of SHRM among the groups was also significantly reduced. The efficacy of SKG0106 at and above 8E9 vg/eye was comparable to that of Eylea®, and the vector demonstrated excellent tolerance profiles. In the prophylactic long-term CNV monkey study, animals were dosed with SKG0106 (6E10 vg/eye) for different observation periods of 6, 13 or 26 weeks. SKG0106 exhibited comparable efficacy to that of Eylea® at 6 and 13 weeks following administration. Importantly, although the efficacy of SKG0106 did not change in the 26-weeks groups, Eylea® did not show the inhibitory effect on the lesions. The thickness of SHRM in SKG0106 group was significantly thinner than that of vehicle group and Eylea® group. In addition, there was no adverse effect detected in the study. No systemic abnormal findings were detected in all pharmacological studies. SKG0106 in all preclinical studies exhibited strong dose-dependent efficacy against vascular leakage in rabbit RNV and monkey CNV models, durable prophylactic efficacy in monkey CNV model, excellent local tolerance profiles and systemic safety. With the support from all these data and the data from long-term GLP toxicity study (data not shown), the vector has entered into clinical stage. (Note: The binding affinity, blockade potency, biodistribution and pharmacokinetics of SKG0106 were studied and discussed in a separate abstract.)

1176 Advancing the High Density Cell Respirator Bioreactor (HDCR) to Overcome Bottlenecks Facing Cell and Gene Therapy

Austin Santiago[1], Colin A. Cook[2], Seonah Kang[3], Yuman Fong[3], Yu-Chong Tai[4], Nicole Bergman[1]

[1]XDemics, Monrovia, CA,[2]City of Hope Beckman Research Institute, Monrovia, CA,[3]City of Hope Medical Center, Duarte, CA,[4]XDemics, Pasadena, CA

Intensification of bioproduction processes will be key to overcoming the bottlenecks facing next-generation cell and gene therapy products. Towards this end, we present advancements to the HDCR bioreactor system, which has been engineered to provide a scalable, universal, and accessible platform for CGT products. The system leverages membranous gas exchange, micro-engineered cell expansion niches, and gentle media perfusion to support cell growth to 10^8 cell/mL densities in a virtually shear-free environment. The HDCR achieves a $k_La > 60$/hr and supports >100-fold expansion of producer cell lines (HEK, Vero, CHO, HeLa), which minimizes seed train demand. In contrast to fiber-based fixed bed bioreactors that tend to act like depth filters, cells are easily recovered intact from the bioreactor, extending application to cell-based products such as stem cells, NK, or CAR-T. Protocols have been established for adherent, suspension, and microcarrier-assisted cultures. The HDCR system comprises a "unit cell" architecture that can be linearly scaled in x and y, and stacked in z affording predictable, linear scaling. For AAV and oncolytic vector processes, we have demonstrated 6,000 fold scaleup while maintaining per-cell productivity. Upcoming studies in our new HDCR Midi platform aim to push scaleup 10-fold further. With an aim to improve operational efficiency in CGT CDMOs and process consistency, we have integrated a 21CFR Part 11 compliant control system, complete with real-time metabolite monitoring (glucose, glutamine, glutamate, lactate) as well as pH, DO, and temperature sensing. The HDCR can be semi-autonomously operated and remotely monitored, which allows it to be comfortably operated by a single technician. To reduce clean room demand and mitigate contamination risk, we have engineered the HDCR to be operable in an entirely closed manner with MicroCNX aseptic connectors allowing for addition or removal of samples from the unit. This allows it to integrate straightforwardly into a closed processing train (i.e. HDCR, chemical or mechanical lysis, chromatography, TFF). The device is operable inside of a standard cell incubator simplifying facility demands. Manufacturing of commercial-grade HDCR units is currently underway using USP Class VI materials for cell contacting components. With these advancements, the HDCR system is nearing readiness for deployment in the CGT community to facilitate process intensification and overcome production bottlenecks.

1177 Non-Viral Persistent Genetic Modification of NK-92 Cells with Non-Integrating S/MAR Vectors for Cancer Immunotherapy

Luisa Burger, João S. Cardoso, Julia D. Peterson, Richard P. Harbottle

German Cancer Research Center (DKFZ), Heidelberg, Germany

Natural Killer (NK) cells form part of endogenous tumour immunosurveillance and have powerful cytotoxic activity against cancer cells. The cell line NK-92 is commonly used in preclinical and clinical studies exploring NK-cell based cancer immunotherapies due to its ease of handling in contrast to primary NK cells, making it suitable for off-the-shelf NK cell therapies. Multiple clinical studies have shown the safe administration of irradiated NK-92 cells to cancer patients, but the therapeutical efficacy has been limited so far. To enhance the anti-tumour activity of NK-92 cells, they can be genetically modified to express a chimeric antigen receptor (CAR) binding to a tumour-specific epitope or to express immunomodulating cytokines. Nevertheless, the genetic modification of NK cells has proven to be very challenging. To modify NK-92 cells, researchers rely mainly on transduction with retro- and lentiviruses. As a natural function of NK cells is to defend against viral infections, NK cells react strongly to viral vectors leading to low transduction efficiencies. Furthermore, transduction bears the risk of insertional mutagenesis and limits the size of the transgenes that can be delivered. We have developed a novel DNA Vector platform which contains no viral components and a minimal bacterial backbone; it does not integrate into the target cell's genome but can replicate autonomously and extrachromosomally in the nucleus of dividing cells using human sequences known as Scaffold/Matrix Attachment Regions (S/MAR). Therefore, these

vectors are excellent candidates for the persistent, stable modification of NK cells without disrupting the genomic integrity of the modified cells. We have developed electroporation protocols and modified our S/MAR vectors to determine optimal vector features to improve the genetic modification of NK-92 cells as these cells are notoriously difficult to transfect. This allowed us to generate an NK-92 cell line which stably expresses a reporter gene without altering its molecular phenotype or limiting the killing activity towards K-562 tumour cells compared to the non-modified parental cell line. The expression of the reporter gene was consistent for at least three months and was not influenced by cryogenic cell storage. The treatment of NK-92 cells with small molecules inhibiting the TBK1/IKKε Kinase complex, a central node of cytosolic DNA sensing, before and after transfection improved transfection efficiencies up to threefold for reporter gene vectors. It furthermore enabled the modification of NK-92 cells with CAR-expressing S/MAR vectors and we will describe protocols for the persistent expression of CARs in NK-92 cells using this vector system. These findings are a first step towards the safer stable modification of NK-92 cells for clinical use and provide a foundation to extend the application of our episomally maintained vectors to primary NK cells.

1178 Harvest Clarification of AAV via Depth Filtration and AEX Functionalized Filters

Priya Katyal[1], Mauhamad Baarine[2], Chris Koehler[3], Daniel Matuszek[1], Ashlee MacLean[1], Helen Achwei[1], Benjamin Rogers[1], Kun Fang[1], Pedro Machado[1], Autumn Tessier[1], Jayda Alves[1], Jeremiah Alves[1], Thomas Perry[1], Matthew Soares[1], Gretchen V. Gee[1], David McNally[1]

[1]MassBiologics, Fall River, MA,[2]3M Separations and Purification Sciences Division, 3M, Northeast Region, Scituate, MA,[3]Product Development, 3M Product Development, St. Paul, MN

Adeno-associated virus (AAV) vector-mediated gene delivery has broad therapeutic implications for a wide array of diseases, particularly for ultra-rare genetic disorders. With the recent clinical and commercial success of AAV vectors, new and better technologies are required that enable process strategy simplification, increased efficiency and reduced cost of goods. The first step in the AAV purification process is primary clarification where the target viral vector product is separated from insoluble cell debris and any precipitated host-cell proteins and DNA. In this work, we evaluated a two-stage depth filter train with varying pore sizes for AAV harvest clarification and compared it to a new chromatographic clarifier comprised of a fibrous anion exchange (AEX) chromatography media and a 0.2 μm polyether sulfone (PES) membrane. The AEX-functionalized chromatographic clarifier has the potential for process simplification by compressing primary clarification to a single stage. We further evaluated the clarification efficiency of the two filter trains in both the presence and absence of a nuclease, with the latter offering a cost reduction opportunity in AAV production. The clarification strategies discussed herein provide simple, efficient, and economical solutions to purify AAVs.

1179 Safe and Effective Delivery of Nucleic Acids Using Proteolipid Vehicles Formulated with Fusion-Associated Small Transmembrane Proteins

Douglas Brown[1], Ping Wee[1], Prakash Bhandari[1], Amirali Bukhari[1], Hector Vega[1], Liliya Grin[1], Maryam Hejazi[1], Jitendra Kumar[1], Paola Solis[1], Natasha Govindasamy[1], Fahed Elian[1], Ivana Machado[1], Natasha Rana[1], Bijal Rawal[1], Brendan Todd[1], Perrin Beatty[1], Roy Duncan[2], Arun Raturi[1], John D. Lewis[1]

[1]Entos Pharmaceuticals, Edmonton, AB, Canada,[2]Dalhousie University, Halifax, NS, Canada

Genetic medicines hold great promise to treat a wide array of diseases, yet success in the clinic has been hindered by limitations in the tolerability, scalability, and immunogenicity of current delivery platforms. We sought to overcome these limitations by combining aspects from viral and non-viral platforms to develop a proteolipid vehicle (PLV) that incorporates fusion-associated small transmembrane (FAST) proteins from fusogenic orthoreoviruses into a well-tolerated lipid formulation using a scalable microfluidic mixing approach. We screened a library of FAST recombinants to identify a chimeric FAST protein with enhanced membrane fusion activity. A series of lipid formulations incorporating the chimeric FAST protein were optimized for high nucleic acid encapsulation, charge neutralization, and improved tolerability *in vitro* and *in vivo*. FAST-PLVs administered systemically in mouse and non-human primate models demonstrated broad biodistribution and significantly improved intracellular delivery and expression of messenger RNA (mRNA) and plasmid DNA (pDNA). At high local or systemic doses FAST-PLVs showed low immunogenicity and maintained activity upon repeat dosing over extended periods. We utilized FAST-PLVs to deliver a pDNA follistatin gene therapy *in vivo* that increased circulating levels of follistatin, resulting in significantly increased muscle mass and grip strength. The activity and safety profile of FAST-PLVs make them a promising platform for redosable gene therapies and genetic medicines.

1180 Evidence of AAV Genome Plasmid Concatemerization within E. coli

Sarah J. Murphy[1], Todd E. Golde[2], Pedro E. Cruz[1]

[1]College of Medicine, University of Florida, Gainesville, FL,[2]Department of Neurology, Emory University, Atlanta, GA

For many years, it has been known that in vivo transduction of recombinant adeno-associated virus (AAV) forms circular genome concatemers in animal models through recombination. But the ability of AAV to form these large concatemers within bacteria has been overlooked. The formation of plasmid concatemers in bacterial cells is a natural phenomenon especially in high-copy-number (relaxed type) plasmids. Bacteriophages also commonly undergo rolling circle replication from a ssDNA template, much like the AAV genome, resulting in large, linear DNA segments that are separated by nucleases and packaged separately. In the present study, we identified the presence of rAAV transgene plasmid concatemers formed within in bacteria during plasmid replication. Originally, we noticed a discrepancy between the predicted sequence length and the results from Oxford Nanopore sequencing of the AAV2 ITRs cloned into the UF11 plasmid

backbone. Sequences ranged from one to five times larger than the anticipated plasmid size of 4570 bp, indicating that concatemerization might be present inside the bacterial cells. The UF11 family of plasmids are unique in having CG clamp adjacent to the ITR (18 C repeats preceding 5' ITR and 18 G repeats following the 3' ITR). To understand the significance of the GC clamp in concatemerization, AAV transgene plasmids lacking the CG clamp sequence also were sequenced. In the non-CG clamp AAV plasmids the concatemerization was limited to duplication of the plasmid during bacteria replication, which confirmed this theory. These results suggest that the UF11 CG clamp enhanced plasmid concatemerization in bacteria with over twice the number of copies as compared to plasmids without the GC clamp. Using next generation sequencing, like nanopore, we were able to find evidence of concatemers plasmid that Sanger sequencing methods were not able to detect. AAV plasmid concatemerization affects how we calculate AAV production by transfection: the assumption of a single copy of genome per plasmid is no longer valid.

1181 Astrocyte-Targeted Gene Therapy Demonstrates Efficacy in Two Murine Models of Vanishing White Matter Disease

Jessica A. Herstine[1,2], Pi-Kai Chang[3], Sergiy Chornyy[1], Jessica Rediger[1], Julia Wentz[3], Nettie Pyne[1], Caleb Holaway[1], Alex Sunshine[1], Erika Scholl[3], Tatyana A. Vetter[1,2], Tamara Stevenson[3], Kevin M. Flanigan[1,2], Joshua Bonkowsky[3], Allison M. Bradbury[1,2]

[1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]Department of Pediatrics, The Ohio State University, Columbus, OH,[3]Department of Pediatrics, University of Utah, Salt Lake City, UT

Vanishing White Matter Disease (VWM), is a leukodystrophy, a neurodegenerative white matter disorder that most commonly occurs in children. Clinically, it presents with ataxia, spasticity, neurological decline, and seizures which lead to premature death. Currently there are no treatments for VWM. VWM is caused by autosomal recessive, loss of function mutations in the subunits of eukaryotic initiation factor 2B (EIF2B), with pathologic variants in EIF2B5 being the most common. Due to VWM's monogenic nature, it is a good candidate for adeno-associated virus (AAV)-mediated gene replacement therapy. VWM pathology suggests that astrocytes are a critical target for therapy, as their differentiation, morphology, and function is impaired, thus mediating disease progression. Therefore, we designed gene replacement constructs to compare astrocyte-specific or ubiquitous expression. Intracerebroventricular (ICV) injections of our vectors expressing the reporter protein GFP into wild-type mice revealed that our astrocyte-specific reporter constructs (AAV9.GFAP.eGFP and AAV9.gfaABC(1)D.eGFP) achieved appropriate transgene expression in astrocytes; with our AAV9.GFAP.eGFP vector having significantly greater biodistribution throughout the neuroaxis when compared to its truncated, or ubiquitous counterparts (AAV9.gfaABC(1)D.eGFP and AAV9.CAG.eGFP). To evaluate potential therapeutic efficacy, we initially generated three constructs driving expression of the *EIF2B5* transgene. However, due to the size capacity of AAV (4.8kb), the GFAP promoter (2.2kb) in combination with the *EIF2B5* transgene (2.2kb) and necessary regulatory elements, led to an oversized construct, subsequent poor packaging, and low viral titers. Because of significant differences in expression between the full-length and truncated astrocyte promoters in our GFP reporter study, we endeavored to increase biodistribution by generating a tailored promoter that restores crucial sequences from the endogenous GFAP promoter into its truncated gfaABC(1)D counterpart. Thus, we created a **novel**, intermediate gfaABCD1405 promoter, and preliminary studies demonstrate expression comparable to full-length GFAP. We evaluated our four AAV constructs in two murine VWM models, *Eif2b5*^{Arg191His} and *Eif2b5*^{Ile98Met}, which display significant gait deficits, myelin loss, and shortened life span, and are monitoring disease progression using traditional and clinically relevant readouts including magnetic resonance imaging (MRI), electroencephalogram (EEG), and gait analysis. Our current data suggests that our astrocyte-targeted gene therapy is able to delay disease progression, partially rescue body weight, and significantly increase latency to fall on rotarod in both disease models; this is to a significantly greater extent than ubiquitous gene therapy. Overall, we anticipate emergence of a lead astrocyte-targeted gene therapy candidate in which the data will be strengthened through the evaluation of clinically relevant measures in two murine models of disease, allowing for timely translation to the clinic. Our findings support the importance of targeting the underlying disease mechanisms through the modification of the AAV vector design.

1182 Targeting Immunosuppressive Tumor-Associated Macrophages Using Innate T Cells for Enhanced Antitumor Reactivity

Yanruide Li

University of California, Los Angeles, Los Angeles, CA

The field of T cell-based and chimeric antigen receptor (CAR)-engineered T (CAR-T) cell- based antitumor immunotherapy has seen substantial developments in the past decade; however, considerable issues, such as graft-versus-host disease (GvHD) and tumor-associated immunosuppression, have proven to be substantial roadblocks to widespread adoption and implementation. Recent developments in innate immune cell-based CAR therapy have opened several doors for the expansion of this therapy, especially as it relates to allogeneic cell sources and solid tumor infiltration. This study establishes in vitro killing assays to examine the TAM-targeting efficacy of MAIT, iNKT, and γδT cells. This study also assesses the antitumor ability of CAR-engineered innate T cells, evaluating their potential adoption for clinical therapies. The in vitro trials presented in this study demonstrate the considerable TAM-killing abilities of all three innate T cell types, and confirm the enhanced antitumor abilities of CAR-engineered innate T cells. The tumor- and TAM-targeting capacity of these innate T cells suggest their potential for antitumor therapy that supplements cytotoxicity with remediation of tumor microenvironment (TME)-immunosuppression.

1183 Development of Adenovirus Serotype 4 Oncolytic and Gene Therapy Vectors as an Alternative to Adenovirus Serotype 5

Erwan Sallard[1], Sebastian Schellhorn[2], Maximilian Maximilian Knocks[3], Lukas Schulte[3], Alexander Klimovitskii[3], Alexander van den Boom[3], Wenli Zhang[4], Anja Ehrhardt[3], Eric Ehrke-Schulz[3]

[1]University Witten/Herdecke, Witten, Germany,[2]University Witten-Herdecke, Witten, Germany,[3]Witten/Herdecke University, Witten, Germany,[4]University Witten/Herdeck, Witten, Germany

Adenoviral vectors are explored for gene therapy and cancer treatment and vaccination. Despite limited applicability caused by preexisting immunity and unfavorable liver tropism, most adenoviral vectors are derived from human Adenovirus 5 (AdV5). We therefore screened an Adenovirus library representing the natural Adenovirus diversity to identify potential alternative adenoviral vector candidates. To compare different AdVs infectivity and AdV mediated and reporter-gene expression we assessed GFP or luciferase activity in variety of cell lines and further tested oncolytic activity using viability assays. Candidate oncolytic vectors were tested on cervical cancer cell mini-organoids. Among many AdV serotypes we found that AdV4 transduced muscle and heart cells more efficiently than AdV5. Moreover, despite low initial transduction efficiency, AdV4 showed oncolytic activity, efficient long lasting gene expression, genome replication and progeny virus production in papillomavirus (HPV) induced tumor organoids. We constructed a first generation AdV4 vector platform by deleting E1 and E3 genes. The E1 and E1-E3-deleted vectors were replication-competent in HEK293 cells, whereas other cancer cell lines including Hela and Siha were not permissive, suggesting that AdV5-E1 can complement for AdV4-E1, enabling the rescue of E1-deleted AdV4. Purified E1, E3 deleted vectors showed similar transduction efficiencies as the parental vector. To increase AdV4 uptake into Papillomavirus induced cancer cells we replaced the AdV4 fiber knob with the AdV5 fiber knob, but pseudotyping did not improve vector infectivity nor replication. Our new AdV4 vector will be further explored for oncolytic or muscle gene therapy and cardiac gene therapy leading the way for the development of further alternative AdV vectors for a broad range of clinical applications.

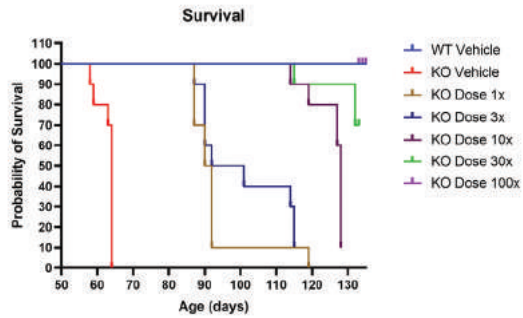
1184 Reversal of Cardiac Phenotype in a Mouse Model of Friedreich's Ataxia Following Administration of AAV Gene Therapy

Joshua C. Chang[1], Whitney Blankenberger[1], Su Liu[1], Marie Stark[1], Jacqueline A. Brassard[2], Tianbi Zhang[1], Fria Bolan[1], Samuel D. Sutton[1], Mario Guerrero[1], José A. Corleto[1], Nakyo Heo[1], Dwaipayan Sen[1], Mark A. Champe[1], Fabrizia Urbinati[1], Bala Medicherla[1], Carlos Fonck[1]

[1]Astellas Gene Therapies, San Francisco, CA,[2]Brassard Toxicologic Pathology Consultancy Corp., Tustin, CA

Friedreich's ataxia (FA) is a multisystem autosomal recessive disease characterized by severe and progressive neuropathy accompanied by hypertrophic cardiomyopathy that is frequently fatal. FA is caused by biallelic GAA trinucleotide repeat expansions in the *FXN* gene that reduces expression of the mitochondrial protein frataxin. We investigated the potential to reverse or prevent progression of the cardiac phenotype in a mouse model of FA, by transferring the human version of the codon-optimized *FXN* gene using an adeno-associated viral vector serotype 8 (AAV8). This AAV construct has a phosphoglycerate kinase (PGK) promoter (AAV-PGK-hFXN) to control the frataxin expression. The cardiac and skeletal muscle-specific frataxin knockout mouse model (KO) has progressive cardiac deficits leading to early mortality. In this study, KO mice received a single intravenous injection of either vehicle or AAV-PGK-hFXN at escalating dose levels (1x, 3x, 10x, 30x, and 100x) to evaluate efficacy and safety at 4- or 12-weeks post-dose. Administration of AAV-PGK-hFXN to KO mice resulted in a dose-dependent reduction in early mortality compared with vehicle-treated KO mice (Fig. 1). In addition, AAV-treated KO mice had statistically significant improvements in ejection fraction and left ventricular mass normalized to body weight ratios compared to mice that received vehicle. Serum biomarkers for cardiac injury including myosin light chain (Myl) and cardiac troponin (cTnI), were 24- and 21-fold higher in vehicle-treated KO mice compared to C57BL/6J wild type mice and were significantly reduced in KO mice following AAV-PGK-hFXN treatment. Transgene DNA was detected in the hearts of AAV-treated mice in a dose-dependent manner. Following the highest dose (100x), exogenous frataxin expression was 14-fold higher in the hearts and ~100-fold higher in the livers of KO mice compared with endogenous levels in WT mice. However, no significant differences were noted in terminal serum alanine aminotransferase or aspartate aminotransferase levels at 4 weeks post-dose when comparing all AAV-treated KO mice to vehicle-treated WT mice. Reduction of myocardial lesions following AAV treatment was consistent with the improvement in cardiac function and the reduction of cardiac injury biomarkers. At 12 weeks post-dose, KO mice that received the two highest doses of AAV-PGK-hFXN, displayed slight to minimal axonal degeneration in the sciatic nerve (30x, 3/10; 100x, 10/10) and, in a few mice, signs of neurodegeneration in the dorsal root ganglion (100x, 1/10). None of these histological changes were accompanied by any clinical manifestations. In addition, the livers of KO mice treated with AAV-PGK-hFXN displayed Kupffer cell hypertrophy and minimal hepatocyte necrosis. These liver changes are commonly associated with AAV gene therapies, are likely related to gene expression, and are considered non-adverse given the low incidence of observations. Overall, dose-dependent efficacy was observed in AAV-PGK-hFXN-treated KO mice compared with vehicle-treated mice based on survival, cardiac function, cardiac injury biomarkers, and histology. These data support the use AAV-based gene transfer as a promising approach to treat patients with FA cardiomyopathy.

Figure 1:



1185 Extracellular Vesicles of Heart-Derived Cells but Not Bone Marrow or Umbilical Cord-Derived Mesenchymal Stem Cells Attenuate NLRP3 Inflammasome Activation in Macrophages

Ramana Vaka[1], Sandrine Parent[1], Saad A. Khan[2], David Courtman[2], Duncan J. Stewart[2], Darryl Davis[1]

[1]Division of Cardiology, University of Ottawa Heart Institute, Ottawa, ON, Canada,[2]Division of Regenerative Medicine, Ottawa Hospital Research Institute, Ottawa, ON, Canada

Background: Intramyocardial injection of heart-derived cells (HDCs) or mesenchymal stem cells (bone marrow, BM-MSCs or umbilical cord, UC-MSCs) has been demonstrated to improve cardiac function in animal models of ischemic heart disease (IHD). This effect in part was attributed to anti-inflammatory microRNA (miRNA) cargo within the extracellular vesicles (EVs) produced by the injected cells. However, it is not known if EVs modulate NLRP3 inflammasome, an innate immune protein complex implicated in the pathology of heart disease. **Objective:** We sought to assess and compare the effect of 3 stem cell derived EVs on NLRP3 inflammasome activation in macrophages; a critical pro-inflammatory cell type. **Methods:** EVs were isolated from conditioned media (ultracentrifugation) and EV miRNA cargo was profiled using multiplex fluorescent miRNA detection (Nanostring). The functional enrichment analysis and miRNA target prediction were performed using bioinformatic tools (Tam 2.0 & miRWalk v3). Monocytes (THP-1) were differentiated into macrophages with phorbol-myristate acetate (PMA; 3 days) and treated with EVs (20 hours) at 3 dose levels (Low:1E+10, Mid:2E+10, High:4E+10 EVs/mL) before inducing NLRP3 inflammasome (lipopolysaccharide; 4 hours & nigericin; 1 hour). The activation of NLRP3 inflammasome was assessed by measuring caspase-1 activity (Caspase-Glo®1 assay), IL-18 & IL-1β levels (ELISA) in the culture supernatants. **Results:** None of the doses of BM- or UC-MSC EVs showed an inhibitory effect on caspase-1 activity. While low or mid doses of HDC EVs failed to show an effect, a high dose (4E+10 EVs/mL) significantly attenuated caspase-1 activity vs. control group (67% lower, n=4-6, $p<0.0001$). Further, EV treated macrophages showed a significant reduction in IL-18 (623±8 vs.1462±43 pg/mL, $p=0.0025$) and a trend towards reduction in IL-1β levels (1292±115 vs. 2535±115 pg/mL, $p=0.08$). However, neither BM- or UC-MSC EVs showed an effect on IL-18 or IL-1β levels. Interestingly, the bioinformatic analysis revealed HDC EVs were enriched with 22 distinct anti-inflammatory miRNAs, of which 4 miRNAs (miR-181a, miR-100, miR-21, miR-22) were predicted to inhibit NLRP3 inflammasome. **Conclusions:** HDC but not BM- or UC-MSC EVs suppress NLRP3 inflammasome in macrophages and this effect in part is possibly mediated via transfer of highly enriched anti-inflammatory microRNA cargo. These preliminary findings prompted us to focus on validating candidate anti-NLRP3 miRNAs in HDC EVs and assessing their immunomodulatory effects using preclinical models.

1186 Strategic Formulation Development for AAV Delivered Gene Therapies-A Case Study

Madhura Som, Sandeep Yadav, Michelle Jones, Saba Ghazvini, Momina Mahmood, Katelyn Esposto, Benson Gikanga

Formulation & Fill/Finish, Sangamo Therapeutics, Brisbane, CA

Formulation optimization (e.g., choice of buffer, pH, excipients) is crucial to developing and stabilizing viral vectors as delivery vehicles for genomic drug products. Phosphate buffers have been widely used for formulating viral vectors for gene therapy due to their well-known clinical compatibility and desired pH range for biopharmaceuticals. However, phosphate buffer is known to show a considerable pH drop in frozen state, which might scale with volume, irrespective of the buffer concentration. For frozen AAV-based drug product (DP), the freeze/thaw cycling during manufacturing and/or storage and handling with associated pH drop may negatively impact the product critical quality attributes (CQAs). To protect AAV-based DPs from freeze/thaw stress, sucrose can be used as a cryoprotectant. In this study, we explored varying sucrose concentrations and their effectiveness in preventing pH drop mediated degradation of AAVs in a phosphate and a non-phosphate buffer formulation, respectively. This work demonstrates strategic selection of buffer (phosphate/non-phosphate) and other excipients (e.g., sucrose) to enable optimal stability of the DP. Further, we present an analytical method (free DNA assay) that can be utilized in optimizing excipient concentration to manage osmolality, density, and endotoxin contributions, for ocular and central nervous system (CNS) routes of administration.

1187 Identification of the Translational Strategy of MAAP and Its Function in AAV Life Cycle

Cagla Aksu Kuz, Kang Ning, Siyuan Hao, Fang Cheng, Jianming Qiu

University of Kansas Medical Center, Kansas City, KS

Adeno-associated viruses (AAVs) are small ssDNA viruses packaging a single stranded genome of 4.7 kb. The left genome encodes 2 large and 2 small replication (Rep)-important nonstructural proteins, Rep78/68 and Rep52/40. The right genome encodes 3 capsid (Cap) proteins (VP1, VP2, and VP3) and two 2 auxiliary small nonstructural proteins, assembly-activating protein (AAP) and membrane-associated accessary protein (MAAP). MAAP is translated from a frameshifted open-reading frame (ORF) located in the VP1 unique coding region. During recombinant AAV (rAAV) production, MAAP played a role in the production of rAAV and/or the regulation of rAAV release from the cell. An additional role of MAAP in genome packaging has also been attributed. However, the exact role of the MAAP in AAV life cycle and its expression strategy remain elusive. Here, we investigated the expression profile and the function of MAAP in the life cycle of both wild-type (wt)AAV2 and wtAAV5, which are phylogenetically distinct serotypes. We found that both AAV2 and AAV5 MAAPs are expressed from *Cap* transcribing mRNA that encodes VP2 and VP3, which is spliced from the major splicing acceptor site (A2). While we confirmed the CTG site for translation of AAV2 MAAP, the ATT codon immediately after the A2 splice site was used to initiate translation of AAV5 MAAP. When MAAP was knocked out in an AAV2 infectious clone, the produced MAAP KO AAV2 mutant tended to be retained

in the cell, whereas virus replication is not affected significantly. Surprisingly, the decrease in virus release was not reinstalled by providing MAAP in *trans* either with plasmid transfection or inducible expression. Interestingly, when MAAP was complemented in *trans*, viral DNA replication was significantly decreased, which is consistent with a decrease in virus replication and expression of viral mRNAs and proteins, suggesting that MAAP may play an additional role in virus life cycle. Importantly, during late phase of wtAAV2 infection, MAAP localized in the same compartment with the capsid in the cytoplasm, which is close to cell outer membrane, providing evidence of possible association of MAAP with capsid during virus release. However, MAAP did not exhibit any colocalization with TGN or ESCRT pathway during wtAAV2 infection, suggesting that a different egress pathway is used for MAAP to escort capsid during virus release. In summary, MAAP is a novel AAV protein translated from the same mRNA encoding VP2 and VP3. Ectopic expression of MAAP decreases viral DNA replication, mRNA transcription, and protein expression. The ablation of MAAP during wtAAV infection causes a significant delay in capsid release; however, the choice of the virus egress pathway is not affected by MAAP.

1188 Development of a Lipid Library for the Optimized Delivery of Self Amplifying RNA

Magalie Plovyt[1,2]

[1]Ziphius, Merelbeke, Belgium,[2]University of Antwerp, Antwerp, Belgium

The self-amplifying RNA (saRNA) platform is an attractive genetic strategy due to its ability to express multiple gene of interests (GOI), higher efficiency in non-dividing cells compared to conventional mRNA, transient activity, and biodegradability. Furthermore, its inherent replication ability distinguishes it from conventional mRNA and could alter the therapeutic window by facilitating higher and longer protein production at lower doses. The major challenge of any nucleic acid (NA) and in particular RNA-based platform is to deliver the molecules to the target cell and subsequently to the cytosol. RNA is sensitive to ribonuclease degradation and NAs in general are unable to cross the cell membrane barrier due to their negative charge. In addition, saRNA specifically is relatively large (over 8kb). Various delivery systems have been developed to protect NAs and shield their negative charge to allow intracellular delivery at the site of action. Lipid nanoparticles (LNPs) have emerged as a promising delivery approach. These are spherical particles formulated when lipids interact with RNA molecules, forming a stable complex protecting NAs against nucleases. Current standard LNPs consists of four lipids: an ionizable cationic lipid, a phospholipid, a sterol, and a polyethylene glycol (PEG) lipid. However, the LNP safety profile and the use of these vehicles for the efficient delivery of large molecules such as saRNA still requires optimization. This study aims to develop LNP-based delivery vehicles which efficiently complex saRNA, thereby ensuring protection against extracellular degradation yet enabling efficient cell uptake and subsequent endosomal escape. Therefore, twenty novel ionizable cationic lipids were designed and synthesized intending the formulation of twenty next-generation LNPs. Initial optimization experiments using a reference ionizable lipid together with the auxiliary lipids were performed to establish standard formulation conditions to test the novel ionizable lipids. A rigorous characterization of the LNPs formulated for each novel ionizable lipid has been performed to determine the size distribution, polydispersity index (PI), charge, and encapsulation efficiency (Enc%). Several exclusion criteria of the physio-chemical properties were chosen to eliminate formulation prior to the in vivo trails: size ≥ 150 nm, PI ≥ 0.3, charge [-20 mv to +20 mv], and Enc% ≥ 80%. All novel formulated LNPs successfully achieved this target product profile. Subsequently, LNPs were intramuscularly administered in mice. To assess saRNA expression efficiency, luciferase-induced bioluminescence was measured via non-invasive in vivo imaging (IVIS) over the course of 20 days. Remarkably, all novel LNPs enabled a positive expression pattern ranging between a 4-6-fold change in log10 scale compared to negative controls (untreated, naked saRNA, and LNPs without ionizable lipid). Next, six formulations with a significantly different total expression (AUC) were identified, either for their higher expression or longevity in comparison to the reference LNPs (positive controls). Accordingly, we report that structural differences of the novel ionizable lipids, including the number of side chains, length of the linkers, as well as the inclusion of functional groups, have a substantial influence on the physio-chemical and biological characteristics of the LNPs.

1189 Development of an *In Vitro* Potency Assay for Neuropeptide-Expressing AAV Vectors Targeting Neurological Diseases

Jeanette Zanker[1], Daniela Hüser[1], Sara Lázaro-Petri[1], Barbara Fogli[2], Christoph Schwarzer[2], Regine Heilbronn[1]

[1]Charité - Universitätsmedizin Berlin, Berlin, Germany,[2]Medical University of Innsbruck, Innsbruck, Austria

Neuropeptide receptors are gaining more and more attention as therapeutic targets due to their modulatory effects on neuronal excitability. However, small molecule agonists for neuropeptide receptors frequently induce unwanted effects due to activation of receptors outside of the target area. Focal application of viral vector-based gene therapies expressing neuropeptides overcomes these obstacles and therefore offer interesting alternatives for long-term treatment. Determining vector potency as a critical quality attribute is important when developing gene therapies and requires a reliable assay for lot release and market approval. With the recent mitigations of FDA regulations concerning the requirements for animal testing, the need to develop robust *in vitro* assays is becoming even more urgent. This may be challenging due to the lack of well characterized human cell lines for specific cell or tissue types. Moreover, available cell lines may not be transduced well by specific AAV serotypes, or lack factors needed for the proper expression or processing of vector-transduced proteins. Using a human neuroblastoma cell line, we have developed an all-in-one biopotency assay that allows parallel determination of RNA, and fully processed neuropeptide expression, as well as viral entry in the same infected microplate well. We compared several preprodynorphin-expressing AAV vectors between our newly developed *in vitro* potency assay and the established *in vivo* assay. Expression levels of fully processed, mature dynorphin B in the cell-based assay correlated with expression levels in vector-transduced mouse brain tissue. The novel human neuronal cell-based *in vitro* assay will facilitate vector screening, allow AAV batch to batch validation, and reduce the need for animals in potency testing.

1190 Nonclinical Development Pathway of a DNA-Encoded Bispecific T Cell Antibody Targeting HER2

Diana Guimet[1], Lauren Jachimowicz[1], Tahsin Jahan[1], Oliver Zhang[1], Alex Guerrero[1], Stephanie Ramos[1], Jeffrey Skolnik[2], Trevor Smith[1]

[1]Preclinical R&D, Inovio Pharmaceuticals, San Diego, CA,[2]Clinical Development, Inovio Pharmaceuticals, San Diego, CA

Bispecific antibodies have revolutionized the treatment of human cancers with significant advances in clinical development surging in the past decade. However, conventional recombinant therapeutics have practical limitations including *in vivo* durability, complex and costly manufacturing, and poor stability. Here, we describe the nonclinical program of a DNA-based medicine (INO-B002) encoding a bispecific antibody targeting epidermal growth factor receptor 2 (ERBB2; HER2) tumor antigen on cancer cells and CD3 on T cells (dBTA-HER2CD3). DNA medicines are highly stable, easier to manufacture, and are expressed *in vivo* for months following a single pDNA treatment delivered with electroporation (EP) technology in preclinical models. Following delivery to muscle tissue of INO-B002, the *in vivo* produced- dBTA-HER2CD3 binds to human CD3 but does not bind to cynomolgus monkey or mouse CD3, thus no pharmacologically relevant animal species exists for testing the toxicity of dBTA-HER2CD3. Therefore, following a pre-IND meeting with the FDA, we implemented a strategy that utilized an *in vitro* approach to assess nonclinical safety. We demonstrate that dBTA-HER2CD3 activates T cells, induces cytokine production, and specifically kills HER2-expressing cancer cells *in vitro.* We observed differential activity in co-cultures with HER2-expressing cancer cells and PBMCs compared to co-cultures with normal cells that express low levels of HER2. *In vivo,* dBTA-HER2CD3 is expressed with measurable levels of functional dBTA detected in both mice and pigs. In addition, dBTA-HER2CD3 controlled tumor growth and improved animal survival in a dose dependent manner in a humanized mouse model. The data collected from these studies has guided the identification of the minimum anticipated biological effect level (MABEL) of dBTA-HER2CD3, which may be used in combination with preclinical pharmacokinetic (PK) studies to determine the starting pDNA dose for a first-in-human (FIH) Phase 1 trial.

1191 Immunosuppression to Inhibit Capsid-Specific Humoral Immune Responses in High-Dose AAV Gene Therapy in Cynomolgus Macaques

Deniz Erturk-Hasdemir[1], Weasel Scott[1], Alexander Kistner[1], Leah Cardwell[2], Justin Serio[1], Lorraine Sullivan[1], Ruta Phadnis[1], Brian E. McIntosh[3], Camille L. Bedrosian[1], Emil D. Kakkis[1], Kathleen McKeever[1], Samuel C. Wadsworth[1], Reed Clark[1], Lorelei Stoica[1], Barbara A. Sullivan[1]

[1]Ultragenyx Pharmaceutical Inc, Novato, CA,[2]Ultragenyx Pharmaceutical Inc, Cambridge, MA,[3]Labcorp Drug Development, Indianapolis, IN

Innate and adaptive immune responses pose a potential limitation for safe and effective gene therapy using recombinant adeno associated viruses (rAAVs). High-dose systemic delivery of rAAV has, in some cases, resulted in serious adverse events such as thrombotic microangiopathy (TMA) and atypical hemolytic uremic syndrome (aHUS) leading to kidney damage due to complement activation. A potential cause is the binding of IgG and IgM anti-capsid antibodies to rAAV vectors in circulation, to form rAAV-antibody complexes, triggering activation of the complement pathway. Thus, immunosuppression (IS) to inhibit the anti-capsid IgM and IgG responses may be useful to mitigate complement-mediated adverse events in high dose gene therapy. Here, immunosuppression with prednisolone, rapamycin and rituximab-pvvr was evaluated for the ability to decrease the development of anti-capsid IgM and IgG. An investigational AAVhu37 gene therapy vector expressing human microdystrophin (μDys) for the treatment of Duchenne muscular dystrophy was dosed at 2e14 VG/kg in male cynomolgus macaques. Pre-screened animals seronegative for both anti-AAVhu37 neutralizing antibodies (NAb) and for AAVhu37 anti-capsid IgGs were included. Animals were divided into 5 study groups. Animals in Group 1 did not receive either IS or rAAV. Animals in Group 2 received rAAV alone. Animals in Groups 3, 4 and 5 received rAAV and IS of prednisolone, prednisolone/rapamycin and prednisolone/rapamycin/rituximab-pvvr, respectively. Plasma, serum, and whole blood were assessed at different time points to evaluate immune endpoints such as anti-capsid IgM, anti-capsid IgG and NAb levels, platelet numbers and complement protein levels. Whole blood was monitored for B cell numbers and rapamycin levels throughout the study. Peripheral B cells were depleted by rituximab-pvvr, and rapamycin levels were above the target level of 12ng/ml for the duration of the study. A transient elevation in liver enzymes (ALT, AST) was observed in all dosed groups four days after vector dosing. The combination of prednisolone, rapamycin and rituximab-pvvr (Group 5) demonstrated a significant decrease in the anti-capsid IgM, IgG and NAb levels compared to the no IS group (Group 2). Four days after vector administration, Group 5 also exhibited significantly higher vector genome DNA levels in the serum, possibly due to the lower anti-capsid antibody levels. A transient increase in complement (C5b9 and C3a) proteins and a transient decrease in platelet numbers were observed in only a subset of animals from all dosed groups within the first week. The combination of prednisolone, rapamycin and rituximab-pvvr was well tolerated and reduced anti-capsid IgM and IgG following high-dose rAAV gene therapy.

1192 The Evolution of a Manufacturing Process for an Integrating AAV Vector: Understanding the Impact of Upstream and Downstream Process Changes

William Lee, Nicholas J. DiGioia, Noel Walsh, Delaney Dowdell, Carmen Wu, Lauren M. Drouin, Matthias Hebben

Alexion, AstraZeneca Rare Disease, Lexington, MA

hLB-001 is an AAV drug product which is being utilized in the clinic for the treatment of pediatric patients with methylmalonic acidemia characterized by methylmalonyl-CoA mutase gene (MMUT) mutations. hLB-001 uses GeneRide™ technology and incorporates homology arms in the vector design to precisely integrate a corrective MMUT gene into the albumin locus of targeted cells through homologous

recombination. Selective advantage is then expected to promote the proliferation of edited cells that express the functional protein. The first generation manufacturing process for hLB-001, which we refer to as Process A, was used to generate an initial batch of product to be used as reference material. Process B is the result of several major upstream changes to boost titer and reduce CoGs, namely through the use of a two-plasmid transfection system and a different transfection reagent. Process C fully transitions Process B from CsCl ultracentrifugation to chromatography-based enrichment in anticipation of large-scale manufacturing. Several assays were used to elucidate the impact of these process changes. Digital Droplet PCR (ddPCR) with primer/probes targeting the MMUT transgene was used to measure total AAV productivity in the bioreactor. Analytical Ultracentrifugation (AUC) was used to determine the percentage of both full and partially filled capsids. The heterogeneity of packaged vector genomes was assessed with two different readouts from Nanopore sequencing: the percentage of reads mapped to different reference sequences, and a measurement of the percentage of full-length vs. fragmented transgenes based on coverage across the transgene. Finally, two different biological potency assays were used to quantify the fused mRNA expression and enzymatic activity of the therapeutic protein. Upstream process changes were found to result in the most dramatic difference in the product profile, while the transition from CsCl enrichment to an anion exchange chromatography enrichment step had a relatively minor impact. Nanopore sequencing assisted in the identification of critical factors in the upstream process that increased the full-length packaging of transgenes into AAV vectors. The results of this study highlight the importance of well developed assays that can detect changes in critical quality attributes and will build a robust understanding of how process changes affect the drug's product profile.

1194 Lentiviral Vectors with Regulated Expression to Treat X-Linked Lymphoproliferative Disease

Paul G. Ayoub[1], Julia Gensheimer[1], Kevin T. Tam[1], Lindsay E. Lathrop[1], Roger P. Hollis[1], Gay M. Crooks[2], Donald B. Kohn[1]

[1]University of California, Los Angeles, Los Angeles, CA,[2]David Geffen School of Med, UCLA, Los Angeles, CA

Introduction: XLP1 is a primary immunodeficiency caused by loss of function mutations in the *SH2D1A* gene, which dysregulates an adaptor molecule, SAP, involved in SLAM-family immune cell signaling. Patients exhibit severe immune impairment - exacerbated following Epstein-Barr Virus infection - which leads to hemophagocytic lymphohistiocytosis, hypogammaglobulinemia, and lymphoma. XLP1 is a monogenic disorder and therefore an excellent candidate for an autologous hematopoietic stem cell (HSC) gene therapy. A previous XLP1 lentiviral vector (LV) gene therapy approach utilized a ubiquitously expressing EFS promoter to encode for the SAP protein. The ubiquitous expression pattern of the EFS LV failed to emulate endogenous regulation of the integrated transgene and suffered from impaired skewing of HSC differentiation. To overcome detriments of ectopic expression, we experimentally elucidated genomic elements that regulate the *SH2D1A* promoter to rationally design LVs that emulate the lineage and temporal specific control of SAP within T, NK, and NKT cells. **Methods:** Elements responsible for regulated expression of the endogenous *SH2D1A* locus, were elucidated by leveraging four genome-wide enhancer databases (ENCODE, VISTA, FANTOM, and Ensembl). We refined each putative element using the UCSC genome browser to minimize sequence length and retain transcription factor binding, epigenetic modifications, enhancer RNA activity, and chromatin interactions. Each element was cloned upstream of the minimal endogenous *SH2D1A* promoter to drive expression of a GFP reporter gene and a unique barcode for multiplexed screening. On-target populations (primary T, NK, and NKT cells) and off-target populations (primary monocytes and B-lymphoblastoid cell lines) were transduced with the barcoded LVs and assessed for their relative enhancer activity by next generation sequencing. Enhancer elements were combined to augment synergistic lineage-specific expression. Expression was assessed *via* GFP mean fluorescent intensity (MFI) in on- and off-target populations, compared to the minimal *SH2D1A* promoter or the ubiquitous EFS promoter. Finally, enhancer temporal expression was confirmed by transducing mobilized peripheral blood CD34+ HSCs with the lead candidate LV to assess GFP+ MFI across T-cell development within the Artificial Thymic Organoid (ATO) system. **Results:** We identified 34 regulatory elements within 200 kb of the human *SH2D1A* gene. Six elements - tested individually - enhanced the minimal promoter activity in T, NK, and NKT cells up to 2-fold. The top 3 enhancer candidates were combined to synergistically **increase expression in on-target populations up to 4-fold** compared to the basal *SH2D1A* promoter and up to 2-fold compared to the previous pre-clinical EFS LV. Furthermore, the XLP-LV demonstrates **no off-target activity**, in contrast to the EFS LV, which contained 3.5-fold greater off-target expression over the basal *SH2D1A* promoter. We also demonstrated that **XLP-LVs mimic temporal expression patterns of SAP** protein throughout T-cell development in ATOs. **Conclusion:** This project delineates not only the first lineage specific LV treatment for XLP1 but also a universal method for the quick identification and incorporation of enhancers into LVs that achieve temporal and lineage specific expression of a target gene. We identified several enhancers of *SH2D1A* that, in combination, increase promoter activity by 4-fold in on-target populations (2-fold greater than the previous EFS LV). The lead XLP-LV also maintains zero off-target expression, unlike the pre-clinical EFS LV counterpart. Current efforts are underway to assess functional restoration of SAP deficient cells in an *in vivo* model.

1195 Programmable Protein Stabilization with Language Model-Derived Peptide Guides

Lauren Hong, Vivian Yudistyra, Sophie Vincoff, Leo Chen, Garyk Brixi, Pranam Chatterjee

Biomedical Engineering, Duke University, Durham, NC

Post-translational modifications (PTMs) of proteins increase functional diversity, but dysregulated alterations can lead to several diseases such as cancer and autoimmune disorders. Specifically, deubiquitination counteracts proteasomal degradation by removing ubiquitin protein chains, thus having several regulatory implications on DNA repair, cell differentiation, and folding catalysis processes. While targeted protein degradation modalities have been developed, a counterpart "targeted protein stabilization" of key regulatory proteins represents a powerful tool to rescue improperly ubiquitin-tagged proteins. Unfortunately, a

significant set of these proteins are considered undruggable by standard small molecule-based therapeutics, due to the lack of binding site accessibility and their disordered nature. As a more programmable, genetically-encoded strategy, designing functional peptide-guided stabilizers provides a unique opportunity for therapeutic interventions. To design a modular architecture for protein stabilization, we leverage protein language models, trained on millions of natural amino acid sequences, to capture diverse biochemical, structural, and functional features of input protein sequences. Specifically, we fine-tune pre-trained protein language models for the specific task of conditionally generating binding peptides provided a target amino acid sequence. We experimentally fuse model-derived peptides to deubiquitinase (DUBs) domains, generating an architecture we term "deubiquibodies" (duAbs), and systematically identify peptide-guided constructs that exhibit robust intracellular deubiquitination in human cells across diverse targets. We further show that our duAbs have negligible off-target effects via whole-cell proteomics and demonstrate re-stabilization of fusion oncoproteins in pediatric cancer cell models, inducing targeted tumor cell death. Overall, our results motivate *in vivo* characterization of our genetically-encoded therapeutic platform for downstream clinical translation.

1196 Novel Strategies to Enhance the Efficacy of CAR T-cell Immunotherapy in Glioblastoma

Alina Brosque[1], Liat Rousso-Noori[1], Dana Tarab-Ravski[2], Shani Nahmias[3], Yarden Engel[4], Michael Berger[4], Marcelle Machluf[5], Dan Peer[2], Dinorah Friedmann-Morvinski[1]

[1]School of Neurobiology, Biochemistry and Biophysics, Tel Aviv University, Tel Aviv, Israel,[2]Shmunis School of Biomedicine and Cancer Research, Tel Aviv University, Tel Aviv, Israel,[3]Faculty of Biotechnology and Food Engineering, Technion-Israel Institute of Technology, Haifa, Israel,[4]The Lautenberg Center for Immunology and Cancer Research, The Hebrew University Medical School, Jerusalem, Israel,[5]Faculty of Biotechnology & Food Engineering, Technion-Israel Institute of Technology, Haifa, Israel

Glioblastoma (GBM) is an extremely aggressive primary brain tumor, with an overall survival of about a year after diagnosis. Conventional therapies have not resulted in major improvements in the survival outcomes of patients with GBM, so increasing efforts are being devoted to develop new therapeutic strategies, particularly in the flourishing field of chimeric antigen receptor (CAR) T-cell immunotherapy. However, CAR T-cell therapy in GBM, and in solid tumors in general, faces several challenges including the high level of heterogeneity that can lead to antigen escape, and the immunosuppressive tumor microenvironment (TME). To overcome the risk of antigen escape we propose the use of dual CAR T-cells that simultaneously recognize a novel but "conventional" tumor associated antigen (TAA) recently identified by our group and expressed on the cell surface, and an "unconventional" target antigen expressed in the tumor extracellular matrix (ECM). TAAs in the ECM are generally more accessible, abundant and stable than those located on the cell surface and provide an advantage in terms of antigen escape. We have demonstrated the specificity and functional activity of the mono-specific CAR T-cells *in vitro*, and their therapeutic efficiency *in vivo*, in murine and human GBM models, and we have encouraging results with different modalities we designed for the dual antigen targeting. In parallel, to overcome the obstacle of the TME, we are working on different combination strategies to enhance the efficacy and persistence of the CAR T-cells. These include the combination with immunomodulatory agents that can revert the immunosuppressive milieu and reinvigorate T-cell effector mechanisms. In order to ensure a localized and safe expression of the agents in the tumor site, one approach consists of using a lipid-nanoparticle (LNP) mRNA based tool for *in vivo* targeted expression with promising preliminary results. In another strategy, we evaluated a potential neoadjuvant therapy based on NanoGhost loaded with an anti-GBM drug and expressing an immunomodulatory receptor. Finally, to enhance CAR T-cell metabolic fitness and overcome the nutrient-deprived TME, we have engineered "metabolically superior" cells capable of using an alternative source of energy. Although GBM is a challenging candidate for CAR T-cell immunotherapy, we consider that the combination of dual CAR T-cells armored with new metabolic abilities, and nanomedicines that can remodel the TME represents a promising therapeutic approach.

1197 Stable Expression of a Secreted HIV Decoy Receptor after *In Vivo* HSC Transduction in Mice and NHPs: Safety and Efficacy in Protection from SHIV

Chang Li[1], Anna Anderson[1], Hongjie Wang[1], Sucheol Gil[1], Jiho Kim[2], Lishan Huang[1], Audrey Germond[1], Veronica Nelson[3], Christopher Peterson[3], John Bui[3], Hans-Peter Kiem[3], Andre Lieber[1]

[1]University of Washington, Seattle, WA,[2]PAI Life Sciences, Seattle, WA,[3]Fred Hutchinson, Seattle, WA

The HIV global pandemic continues with an annual incidence of 1.5 million new HIV infections per year. New approaches are needed to overcome issues of pre-exposure prophylaxis as well as therapy of established HIV infection. Autologous hematopoietic stem cell (HSC) gene therapy is a promising strategy for the treatment of HIV/AIDS. However, despite encouraging preclinical and clinical results, current *ex vivo* HSC gene therapy protocols are complex, expensive and associated with significant toxicities. We aim to develop an *in vivo* hematopoietic stem cells (HSC) gene therapy approach for persistent control/protection of HIV-1 infection based on the stable expression of a secreted decoy protein for HIV receptors CD4 and CCR5 (eCD4-Ig) from blood cells. HSCs in mice and a rhesus macaque were mobilized from the bone marrow and transduced *in vivo* by an intravenous injection of HSC-tropic, integrating HDAd5/35++ vectors expressing rhesus eCD4-Ig. *In vivo* HSC transduction/selection resulted in stable serum eCD4-Ig levels of ~100 μg/ml (mice, 32 weeks) and >20 μg/ml (rhesus 57 weeks) with IC_{50}s of 1 μg/ml measured by an HIV neutralization assay. The *in vivo* HSC transduction approach and high level eCD4-Ig serum levels were well tolerated without abnormalities in hematological parameters. After high- dose, intravenous SHIV.D challenge of rhesus macaques injected with HDAd-eCD4-Ig or a control HDAd5/35++ vector, peak plasma viral load levels were ~50-fold lower in the eCD4-Ig expressing animal. Furthermore, the viral load was lower in tissues with the highest eCD4-Ig expression, specifically the spleen and lymph nodes. SHIV.D challenge triggered a selective expansion of transduced $CD4^+CCR5^+$ cells, thereby increasing serum eCD4-Ig levels. The latter, however, broke immune tolerance

and triggered anti-eCD4-Ig antibody responses, which could have contributed to the inability to eliminate SHIV.D. Our data will guide us in the improvement of the *in vivo* approach. Clearly, our conclusions need to be validated in larger animal cohorts.

1198 Small Nuclear RNA-Mediated Exon 51 Skipping AAV9 Gene Therapy for the Treatment of Duchenne Muscular Dystrophy

Rea Lardelli Markmiller, Greg Nachtrab, Claire Geddes, Taka Tadokoro, Sheik Pasha, Daniel Knowland, Daniela Roth, Alberto Carreno, Gustavo Villegas, Anindita Sarkar, Derek Reid, Lynn Nguyen, Rachel Adams, Oscar Diago, Shruti Vakharia, Bryan Almaguer, Haydee Gutierrez, Yesol Go, Ronald Torres, Nandini Narayan, Deepti Vashist, Aaron Berlin, Amanda Tran, Ranjan Batra, John E. Leonard

Locanabio, San Diego, CA

Duchenne Muscular Dystrophy (DMD) is an X-linked fatal neuromuscular disorder characterized by progressive muscle weakness and loss of ambulation by teenage years, affecting ~1:5000 males aged 5-9[1]. DMD is caused by mutations which shift the transcript reading frame of the *DMD* gene and result in little to no dystrophin protein. Approved exon skipping antisense oligonucleotides (AON) restore the *DMD* reading frame, creating a slightly internally truncated but functional dystrophin protein; however, these treatments show low levels of exon skipping and dystrophin production in skeletal muscle and heart due to poor tissue uptake in disease-relevant tissues. AAV9 gene therapy carrying multiple small nuclear RNAs (snRNAs) programmed to target one or more splice regulatory sequences simultaneously with high precision and potency has shown great therapeutic potential with unprecedented levels of exon skipping in DMD patients[2,3]. The challenge in viral packaging of snRNA genomes is that the repetitive snRNA sequences are prone to truncations/recombinations leading to low titers and inconsistent transgene expression. To overcome these challenges, we have developed a novel snRNA packaging strategy, which minimizes repetitive sequences within the genome and leads to high titer, full-length self-complementary virus with the intended genome as confirmed by long-read sequencing. Using this packaging strategy, we engineered snRNAs to target two different exon splicing enhancer sequences within exon 51 of *DMD* and delivered this construct to patient-derived cells and del52hDMD/*mdx* mice by intramuscular (IM) or intravenous (IV) injection. We report dose-dependent exon 51 skipping up to 100% in patient-derived cardiomyocytes and myotubes and upregulation of dystrophin expression. Four weeks after IM treatment, del52hDMD/*mdx* mice show up to 86% exon 51 skipping in skeletal muscle, and 3 weeks after IV treatment up to 73% in skeletal muscle and 90% in heart. Importantly, dystrophin protein levels were upregulated in skeletal and heart tissues in del52hDMD/*mdx* mice with improvements in muscle pathology observed with IM injections. Further, IV delivery of our construct led to lowering of serum creatine kinase (CK) and AST/ALT levels implying reduced muscle damage upon treatment. In summary, our novel designs allow for high-titer viral packaging of full-length AAV genomes carrying multiple highly expressing snRNA cassettes which we show to effectively skip DMD exon 51 and which can be rapidly deployed to therapeutically skip other *DMD* exons by switching antisense targeting sequences. 1. Zhang et al., Neuroepidemiology 2021. 2. Simmons et al., Mol. Ther. Methods Clin. Dev. 2021. 3. Megan Waldrop, ASGCT 2022.

1199 Development of Strategy for Multi-Dose Gene Therapy in Murine Model of Glycogen Storage Disease Type Ia

Charles Arends[1,2], Yasir Ameen[1], Young Mok Lee[1,2]

[1]Department of Pediatrics, University of Connecticut School of Medicine, Farmington, CT,[2]Genetics and Genome Sciences, University of Connecticut Health Center, Farmington, CT

Background: Glycogen storage disease type Ia (GSD-Ia) is caused by a deficiency in glucose-6-phosphatase-α (G6Pase-α or G6PC), an enzyme that catalyzes the hydrolysis of glucose-6-phosphate to glucose in the terminal step of glycogenolysis and gluconeogenesis. Patients with GSD-Ia manifest severe fasting hypoglycemia, metabolic disturbances, and slowed growth with delayed puberty onset. Previously, a recombinant adeno-associated virus (rAAV)-mediated gene therapy had demonstrated its ability to correct fasting hypoglycemia as well as hepatic abnormalities in model animals of GSD-Ia. The study's results led to human clinical trials started in 2017. While the phase 1/2 clinical trial made great strides in the clinical treatment for adult GSD-Ia patients, the newborn and young patients still need to manage the severe phenotype daily. Gene therapy for infant patients could be the ultimate treatment for these life-threatening symptoms. However, the efficacy of this vector when administered at a newborn age has yet to be fully investigated. Previously, it has been shown that transduced rAAV vectors are gradually diluted out or partially lost in the livers of young animals due to the high rate of hepatocyte proliferation associated with liver growth. Thus, 2 separate doses of this vector, newborn and adult, may prove to be the most advantageous method for improving gene therapy in liver directed models. In this perspective, we evaluate the use of endogenous growth factors linked with hepatocyte proliferation to determine optimal age of gene therapy vector administration to minimize vector dilution with GSD-Ia knock-out mice. **Methods:** In this study, we used a GSD-Ia mouse model with complete knockout of G6PC. rAAV vector expressing G6PC was administered in neonatal mice. To gage liver growth rate in the mice we analyzed the growth factors that play major roles in hepatocyte proliferation: growth hormone (GH), epidermal growth factor (EGF), transforming growth factor alpha (TGF-α), and hepatocyte growth factor (HGF). We administered 2nd dose of AAV gene therapy vector based on the concentration of the growth factors and then examined the efficacy of the vector by assessing fasting glucose levels, G6PC gene expression, and vector copy numbers in the livers of treated GSD-Ia KO mice. **Results:** We show that after rAAV administration in neonatal mice, survival rate of GSD-Ia KO mice is greatly increased but still have slowed growth. GH, EGF, TGF-α, and HGF serum levels were assessed at 2, 4, 6, 9, and 12 weeks and compared with the growth rate of the KO mice to estimate hepatocyte proliferation rate. Additionally, we observed low fasted glucose levels as early as 6 weeks of age in KO mice, indicating lower efficacy of the vector at this time point. Vector copy numbers and gene expression of G6PC were quantified following the fasting glucose test in the various age groups to evaluate the strategy to determine AAV vector administration age. **Conclusion:** In severe congenital liver diseases, such as GSD-Ia, therapeutics including gene

therapy in newborns would greatly improve the quality of life for patients given the extreme difficulty to properly manage symptoms in infants. This may require a second dose at adult age and determining the optimal timing of a second dose of rAAV will be critical for higher long-term efficacy of the treatment. This study gives examines the correlation of proliferation biomarkers and liver growth rates to shed more light on this concern.

1200 Base-Editing as a Safe and Highly Effective Alternative Treatment for X-SCID Compared to CRISPR-Cas9 Nuclease Editing with an AAV Donor

Vera Bzhilyanskaya[1], Julie Brault[1], Siyuan Liu[2], Nikita Kozhushko[1], Amanda Lawson[1], Mara Pavel-Dinu[3], Aaron B. Clark[4], Ronald J. Meis[4], Michelle Ma[1], Cicera R. Lazzarotto[5], Shengdar Q. Tsai[5], Xiaolin Wu[2], Gary Dahl[4], Benjamin P. Kleinstiver[6], Matthew H. Porteus[3], Harry L. Malech[1], Suk See De Ravin[1]

[1]LCIM, NIH, NIAID, Bethesda, MD,[2]NCI, Frederick, MD,[3]Stanford University, Palo Alto, CA,[4]CELLSCRIPT, LLC, Madison, WI,[5]St. Jude Children's Research Hospital, Memphis, TN,[6]Massachusetts General Hospital, Boston, MA

Genome editing offers great potential for improved safety and efficacy for *ex-vivo* hematopoietic stem/progenitor cell (HSPC) gene editing, including for the treatment of Inborn errors of immunity (IEI) and other blood disorders. When considering the safety of correcting mutations, different gene editing approaches have advantages and caveats. For example, targeted integration (TI) using exogenous DNA donors following CRISPR-Cas9 nuclease mediated double strand DNA breaks (DSB) via homology-mediated repair (HDR) has demonstrated high TI efficiencies for correction of multiple IEIs. However, DSBs and DNA damage responses (DDR) following DSBs may be compounded by exposure to DNA donors, potentially impairing HSPC fitness and long-term engraftment. Here we compare the safety and efficacy of correcting an *IL2RG* mutation in HSPCs from a patient with X-linked Severe Combined Immunodeficiency (X-SCID). To treat X-SCID, current *ex vivo* HSPC gene therapy uses integrating retroviral vectors. While this treatment provides substantial clinical benefit, insertional oncogenesis remains a risk. We therefore sought to revert the *IL2RG* mutation using a DSB/HDR approach (GE) with CRISPR-Cas9 and an AAV donor compared to base-editing using an Adenine Base Editor (ABE8e-SpCas9). To make this comparison, GE and BE XSCID HSPCs were processed with CRISPR-Cas9 nuclease and an AAV6-IL2RG donor with i53 (favors HDR) and Genetic Suppressor Element (GSE, dampen DNA damage response) or ABE-8eSpWT base-edited HSPCs, which were transplanted into immunodeficient NOD.Cg-Prkdc^{scid} Il2rg^{tm1Wjl} Tg mice pups. We assessed engraftment capabilities following editing since this is a major concern for gene targeted HSPCs, especially following DSBs. Transplanted mice were harvested at 16-24 weeks, and engraftment rates (hCD45+ cells) were similar between GE (with optimal addition of GSE) and BE transplanted mice (GE: 13.01% [SD: 7.81], BE: 13.52% [SD: 7.27]). The addition of GSE has likely mitigated the DDR-related adverse impact on engraftment. *IL2RG* is essential for the differentiation and function of lymphocytes, thus accounting for the profound immunodeficiency in patients with X-SCID. T cell reconstitution in transplanted mice was assessed by evaluating the percentages of circulating T cells (CD3+) as well as IL2RG expression of IL2gc. Although no significant difference in the % of CD3+ cells was observed between GE (79.77% [SD: 35.65]) and BE (91.45% [SD: 22.39]) mice, IL2gc expression in CD3+ T cells was significantly (p=<0.0001) greater in BE mice (93.85% [SD: 4.30]) compared to GE mice (59.89% [SD: 21.01]). Molecular analysis for phenotypic genetic correction of X-SCID HSPCs was assessed by digital droplet PCR for TI in GE HSPC and high throughput sequencing of target site for BE HSPCs. Mice bone marrow cells sorted for hCD45 cells revealed a significantly higher rate of mutation repair achieved by BE (84.55% [SD: 19.14]) than GE-mediated rates of TI (55.36 [SD: 18.01]). High throughput sequencing of off-targets identified by *in vitro* CHANGE-seq assay confirmed the highly specific targeting of both genome editing strategies. Base-edited X-SCID HSPCs displayed comparable engraftment and T cell development in transplanted mice compared to GE XSCID HSPCs. Of note, BE achieved significantly higher levels of genetic correction, making this a safer and more effective approach for *ex vivo* gene therapy for X-SCID patients with an *IL2RG* c.444C>T mutation.

1201 Can *PTEN-L* Gene Therapy Rescue PTEN Hamartoma Tumor Syndrome (PHTS)-Related Tumor and Behavioral Phenotypes in Mice?

Indumathy Jagadeeswaran, Kyungho Park, Sarah E. Sinnett

University of Texas Southwestern Medical Center, Dallas, TX

Introduction: The tumor suppressor *PTEN* is one of the most frequently mutated genes in human cancer and may cause up to 5% of autism cases. Patients with *PTEN* Hamartoma Tumor Syndrome (PHTS) have germline mutations in *PTEN* and can suffer from tumor and/or autism-related phenotypes. Female PHTS patients have about an 85% lifetime risk of breast cancer. Preventive gene therapy may improve their quality of life by decreasing the burden of frequent tumor monitoring. The longer PTEN proteoform PTEN-L is well-suited for gene therapy due to its cell-penetrating properties. Indeed, daily injections of purified PTEN-L have been shown to inhibit PTEN-null tumor growth *in vivo*. This study seeks to develop a dual-purpose adeno-associated viral vector serotype 9 (AAV9)/*PTEN-L* gene therapy for treating *PTEN*-related tumors and behavioral abnormalities. Because the endogenous PTEN signaling pathway is homeostatically regulated, one may hypothesize that unregulated *PTEN* gene therapy may cause predictable, counter-productive side effects (e.g., hyperinsulinemia) that warrant the development of regulated, second-generation gene therapies. Methods: To assess the safety of human *PTEN-L* gene transfer, male wild-type (WT) mice were injected intravenously with either vehicle or AAV9/hP599-*PTEN-L-myc* or AAV9/Cbh-*PTEN-L-myc* (1E12 vg/mouse at postnatal day P38). The hP599 promoter is a variant of the human *PTEN* promoter; CBh is a stronger, ubiquitous promoter. Blood insulin levels and peripheral PTEN-L expression were analyzed at 24 weeks post-injection. To evaluate tumor remission, female athymic nude mice (*Foxn1^{nu}*) were injected with vectors at P65-P79 and were engrafted four weeks later with PTEN-null MDA-MB-468 breast cancer cells (1E6 cells/mouse). To assess anxiety and depression, open field and tail suspension tests were conducted one month after male *PTEN$^{-/+}$* mice were injected intrathecally with either vehicle or AAV9/hP599-*PTEN-L-myc* (3E10 or 1E11 vg/mouse;

P32-P34). Results: Consistent with our hypotheses, AAV9/CBh-*PTEN-L*-myc accelerated tumor growth and caused death in about 20% of mice. In contrast, AAV9/hP599-*PTEN-L*-myc permitted 56% tumor remission by 30 days post-xenograft and did not cause any deaths. Because the hP599 vector caused weight gain and hyperinsulinemia, the development of a regulated second-generation hP599 vector may be warranted. Although not statistically significant, preliminary behavioral data trends toward normalization in the tail suspension test. Characterization of PTEN-L expression in peripheral post-mitotic tissue is ongoing. Conclusion: AAV9/hP599-*PTEN-L* demonstrated modest efficacy with anticipated side effects that may - conceptually - confound efficacy results. An improved, regulated vector design may mitigate side effects and unveil the full therapeutic potential of *PTEN-L* gene therapy.

1202 Neutrophil-Specific Single-Cell RNA-Sequencing Discovers a Novel Smad3-Dependent Immunosuppressor Prdm2 for Promoting NSCLC

Yat Fai Chung

Department of Anatomical and Cellular Pathology, The Chinese University of Hong Kong, New Territories, Hong Kong, Hong Kong

The functional role of tumor-associated neutrophils (TAN) in cancer progression is still controversial and largely unknown. Interestingly, we observed that Smad3 deficiency dramatically increase TAN population in mouse cancer model with syngeneic lung carcinoma LLC. By conducting a neutrophil-specific 10x single-cell RNA-sequencing, we uncovered the heterogeneity and transcriptomic dynamics of TAN in the Smad3-depedent tumor microenvironment (TME). Surprisingly, we found several novel TAN subsets in the Smad3-null TME which were highly distinct to the wildtype TAN. Gene ontology analysis suggested transcriptomes of the wildtype TAN were highly associated with cell cycle arrest and senescence; supporting by the prolonged lifespan of the Smad3-KO TAN in vitro and in vivo. Mechanistically, ChIP-sequencing discovered a quiescence mediator Prdm2 as a novel Smad3 direct target gene in TAN under cancer condition in vitro and in vivo, which significantly associated with NSCLC mortality. More importantly, adoptive transfer of Prdm2-silenced bone marrow derived neutrophils markedly inhibited the progression of LLC-tumor in mice. Thus, we discovered Prdm2 as a Smad3-dependent immunosuppressor of TAN, which may represent as a novel therapeutic target for cancer.

1203 Evolution of Blood-Brain Barrier Penetrant AAV Capsids in Non-Human Primates Using a Multiplexed Transcription Dependent Capsid Engineering Platform

Matthew R. Tiffany[1], Stephanye Frias[1], Lori Andrews[2], Ankitha Nanjaraj[3], Yuri Bendaña[3], Russell Darst[3], Stephen Wist[3], Hung Tran[3], Kenneth Kennard[3], Sarah Mueller[3], David Ojala[3], Amy Pooler[3]

[1]Sangamo Therapeutics, Inc., Brisbane, CA,[2]Sangamo Therapeutics, Richmond, CA,[3]Sangamo Therapeutics, Inc., Richmond, CA

Many devastating diseases of the central nervous system (CNS) have the potential to be ameliorated with genomic medicines. Adeno-associated virus (AAV) is one of the most promising viral delivery modalities for gene therapy, however, transport of AAV across the blood-brain barrier poses a significant clinical challenge. Here, we employed the functional selection platform, SIFTER (Selecting *In vivo* for Transduction and Expression of RNA), to engineer capsids that transduce the CNS following intravenous administration in cynomolgus macaques. SIFTER is distinguished from other library screening strategies by the implementation of a divergent expression cassette and barcode look-up table to track capsid performance. This allows for multiplexing of different parental serotypes and diversified capsid regions in a single head-to-head experiment. For each capsid variant, multiple replicate barcodes and unique molecular identifiers (UMIs) are utilized to improve quantification of capsid performance in difficult-to-transduce tissues, including the brain. CNS-tropic capsids previously identified in a first SIFTER screening round were synthesized in a new multiplexed library of 65,000 variants comprising ten library designs across four parental AAV serotypes. In this second round of screening in cynomolgus macaques, we analyzed capsid performance in both mRNA expression and DNA delivery across the brain, spinal cord, dorsal root ganglion, and select peripheral tissues. A custom bioinformatics suite was developed to demultiplex each sub-library and compute multiple capsid performance and similarity features that describe the level and consistency of CNS transduction. The results show multiple new capsid variants with improved CNS transduction following intravenous administration relative to benchmark capsids. Blood-brain barrier penetrant capsids identified in this study will be evaluated individually for their potential utility in treating CNS disorders.

1205 Efficacy and Safety of a SOD1-Targeting Artificial miRNA Delivered by AAV9 in Mice Are Impacted by miRNA Scaffold Selection

Shih-Ching Joyce Lo

Biogen, Cambridge, MA

Toxic gain-of-function mutations in superoxide dismutase 1 (SOD1) contribute to ~2-3% of all amyotrophic lateral sclerosis (ALS) cases. Artificial microRNAs (amiRs) delivered by adeno-associated virus (AAV) have been proposed as a potential treatment option to silence SOD1 expression and mitigate disease progression. Primary microRNA (pri-miRNA) scaffolds are used in amiRs to shuttle a hairpin RNA into the endogenous miRNA pathway, but it is unclear whether different primary miRNA scaffolds impact the potency and safety profile of the expressed amiR *in vivo*. In our process to develop an AAV amiR targeting SOD1, we performed a preclinical characterization of two primary miRNA scaffolds, miR155 and miR30a, sharing the same guide strand sequence. We report that while the miR155-based vector, compared to the miR30a-based vector, leads to a higher level of the amiR and more robust suppression of SOD1 *in vitro* and *in vivo*, it also presents significantly greater risks for CNS-related toxicities *in vivo*. Despite miR30a-based vector showing relatively lower potency, it can significantly delay the development of ALS-like phenotypes in SOD1-G93A mice and increase survival in a dose-dependent manner. This data highlights the importance of scaffold selection in the pursuit of highly efficacious and safe amiRs for RNAi gene therapy.

1206 Phase I/II Trials with Sleeping Beauty Engineered CAR T Cells of Donor Origin for B-cell Acute Lymphoblastic Leukemia

Chiara F. Magnani[1,2], Federico Lussana[3], Giuseppe Gritti[3], Giuseppe Gaipa[1], Stefania Galimberti[4], Daniela Belotti[1], Sara Napolitano[5], Chiara Buracchi[1], Gian Maria Borleri[3], Benedetta Rambaldi[3], Giuliana Rizzuto[3], Anna Grassi[3], Muriel Paganessi[3], Fabrizio Benedicenti[6], Giulia Pais[6], Sarah Tettamanti[1], Giovanni Cazzaniga[1], Silvia Ferrari[3], Chiara Capelli[7], Elisa Gotti[7], Martino Introna[3], Eugenio Montini[6], Adriana Balduzzi[5], Maria Grazia Valsecchi[4], Giuseppe Dastoli[1], Alessandro Rambaldi[3], Andrea Biondi[1]

Lanzani", Bergamo, Italy

A major challenge limiting the clinical application of academic CAR T-cell immunotherapies is the manufacture of cell products using viral vectors and patient-derived material. We recently proposed the use of Sleeping Beauty (SB) transposon to engineer donor-derived CAR T cells differentiated toward the CIK population (CARCIK-CD19) for the treatment of B-cell acute lymphoblastic leukemia (B-ALL) patients relapsed after allogeneic hematopoietic stem cell transplantation (allo-SCT). Here we report the final results of phase I/II study evaluating the safety and efficacy of CARCIK-CD19 cells in 21 patients (NCT03389035). Six additional patients were treated on a compassionate-use basis. Cells were manufactured from HLA-identical siblings, matched unrelated, and haploidentical donors. After lymphodepletion with Fludarabine and Cyclophosphamide, patients received a single infusion. Bridging therapy was allowed. A total of 27 patients (4 children and 23 adults) were infused. Successful production of CARCIK-CD19 cells was achieved for all patients. The first 9 patients were treated in dose-escalation (1x10^6/kg, 3x10^6/kg, and 7.5x10^6/kg), whereas the remaining 18 patients received 15x10^6 cells/Kg, as no dose-limiting toxicity was observed. The median number of prior therapies was 4 (range, 2-8). The median BM blast was 40% at enrolment and 1.7% after lymphodepletion. CRS occurred in 9 patients (4 grade I and 5 grade II) and ICANS (grade 3) in 2 patients at the two highest doses. Although 10 out of 27 had experienced GvHD after the previous allo-SCT, GvHD never occurred after treatment with CARCIK-CD19. Nine patients had infections, of which 6 of grade 3 or higher. CR was achieved by 18 out of 27 patients (66.7%, 95%CI=46.0-83.5%) and by 16 out of 21 patients treated with the two highest doses (76.2%, 95%CI=52.8-91.8%, 81.3% MRD-negative). With a median follow-up of 2.8 years (range, 0.05-4.4 years), at 6 months, the EFS and OS were 41.5% (SE=11.6) and 71.4% (SE=9.9), respectively. The 6-month DOR of 54.4% (SE=13.8). Robust CAR T-cell expansion was achieved in most patients and CAR T cells were measurable for up to 27 months, in association with B cell aplasia. Integration site analysis of the patient's peripheral blood demonstrated highly polyclonal marking. No signs of genotoxicity by transposon insertions could be observed. SB-engineered CAR T cells of donor origin showed an excellent safety profile with anti-leukemia activity in heavily pretreated patients with B-ALL.

1207 A Human-Centric AAV Capsid Engineering Platform for the Targeting of Dysfunctional Neural Circuits

Alba Guijarro Belmar, Hanna Luniak, Panayiota Demosthenous, Riccardo Privolizzi, Calvin C. Smith, Miranda Mathews, Raj S. Dattani, Robert M. Brownstone, Andrew J. Murray

Sania Therapeutics, London, United Kingdom

The fundamental cause of many neurological disorders can be attributed to the abnormal electrical activity of specific neural circuits. Normalizing activity in these dysfunctional neurons should therefore be a valuable avenue for the development of therapeutics, and ultimately the treatment of various nervous system conditions. However, for this to be a successful therapeutic approach, specific targeting is required so that anomalous neuronal activity can be corrected in the dysfunctional circuit, without altering the properties of neighbouring cells and brain regions. To advance the treatment of neural circuit disorders, Sania Therapeutics is leveraging a combination of intersectional technology platforms that allow for the targeted delivery of chemogenetic proteins through engineered AAV capsids and promoters. This approach will allow us to specifically modify neural circuit activity in disease states while minimizing side effects associated with current therapies. Directed evolution of AAV capsids has shown promise for targeting gene delivery to specific cell and tissue types, including sub-classes of neurons. However, the evolution and identification of new capsid variants has shown limited translatability across animal species and from animals to humans. Indeed, individual evolved capsids can have quite different tropisms across species making it difficult to predict how these vectors will perform when used in clinical gene therapies. Sania's R-Scan™ AAV evolution platform is designed to overcome these deficits by taking a human-first approach to capsid screening. In order to maximise the utility of our R-Scan™ platform we have generated 16 different capsid libraries based on multiple parental serotypes and diversification strategies. We have used the parental serotypes AAV1, AAV2, AAV5, AAV6, AAV8, and AAVrh10 all selected based on published studies showing useful features such as neuronal tropism, ability for retrograde transport within neurons, and low seroprevalence within the general population. To achieve a series of libraries with maximal functional variants we used a combination of random mutagenesis in the full length of the gene, mutagenesis of the external loops of the capsid, and insertions in specific locations of the capsids of either random peptide sequences or rationally designed motifs known to target our cell type of interest. Our mutagenesis libraries contain over 1 million variants each, while our semi-rational designs have around 25K variants. All these libraries were packaged in-house and characterized by PCR, qPCR, NGS sequencing, and functional testing in different cell types. Screening of these capsid libraries is carried out

in our R-Scan™ platform. This platform allows us to recreate human neural circuits in vitro and target capsid evolution to a specific neuronal sub-type. Our initial studies have focussed on the generation of human motor neuron-muscle circuits for the identification of AAV vectors that can efficiently infect human motor neurons via intramuscular injection. This in vitro circuit uses microfluidics to recreate the functional barrier between motor neuron terminals in the periphery and their cell bodies in the central nervous system. Our human motor neurons are derived in house from a pool of donor hIPSC cell lines from people of different sexes, ages and ethnicities in order to maximise translatability of these capsids across the clinical population. The R-Scan™ platform can be applied to multiple neuronal circuits and cell types and so can provide capsid variants for therapeutic uses in multiple nervous system disorders.

1208 Neutrophils Conspire with CD8+ Exhausted T Cells to Promote Breast Cancer Lung Metastasis upon Loss of BRD7

Jayanta Mondal[1], Junfeng Zhang[2], Filippo Giancotti[2], Jason Huse[1]

[1]Translational Molecular Pathology, University of Texas MD Anderson Cancer Center, Houston, TX,[2]Cancer Biology, University of Texas MD Anderson Cancer Center, Houston, TX

Introduction: Thwarting metastasis is regarded as the holy grail in the treatment of cancer as metastasis accounts for more than 90% of cancer-related deaths. Intriguingly, even though epigenetic alterations have been widely implicated as a universal aspect across cancer types, little is known about how epigenetic events can engender metastasis by reprogramming the tumor immune microenvironment . Additionally, the mechanism(s) by which the loss of SWI/SNF chromatin remodeling complex subunits-like Bromodomain-7(BRD7)- induces dormant breast cancer cells to metastasize to the lung hasn't been deciphered .**Methods:** We established a novel high throughput *in vivo* screening platform which enables the identification of specific epigenetic entities that regulate metastatic reactivation. RNA-seq enabled the identification of the signaling pathways that govern metastatic dormancy. Furthermore, tumor sphere and invasion assays were performed. In order to decipher the chromatin accessibility regions regulating metastatic reactivation, ChIP-seq and ATAC-seq were conducted. A magnetic bead-based multiplex cytokine assay informed us about the regulation of cytokines. *In vivo* experiments were performed in the 4TO7-TGL and D2A1-d dormancy models and in the NSG immunodeficient mice model. Further, FACS immune-phenotyping coupled with scRNA-seq were implemented to comprehend the changes in the tumor immune microenvironment upon loss of BRD7. Finally, neutrophil and CD8+ exhausted T cell depletion was carried out by using the anti-Ly6G Ab and anti-CTLA4+anti-LAG3 Abs. **Results:** The loss-of-function screen revealed that loss of BRD7 resulted in the dormant breast cancer cells metastasizing to the lung *in vivo*. Interestingly, RNA-seq revealed that BRD7 knockout promotes the expression of genes involved in inflammation, hypoxia and EMT. Intriguingly, the top signaling pathways enriched in BRD7-silenced cells were IL6-JAK-STAT3 signaling, TNF-α signaling, and Interferon-Gamma responses. Further, ATAC-seq and ChIP-seq experiments indicated that inactivation of BRD7 caused an increased accessibility of enhancer and super-enhancer sites that were enriched for interferon-regulated response element sites. Additionally, we found that BRD7-kncokout induces the up-regulation of pre-metastatic cytokines like IL6, IL33, CXCL10, and CXCL12. scRNA-seq coupled with FACS informed us that the loss of BRD7 led to up-regulation of the tumor-promoting N2 neutrophil population and CD8+ exhausted T cells while down-regulating the tumor-suppressive M1 macrophages and dendritic cells *in vivo*. Finally, depleting neutrophils using the anti-Ly6G Ab prevented the BRD7 KO-induced lung metastasis *in vivo*. Furthermore, the efficacy of the combination of anti-LAG3+anti-CTLA4 Abs towards preventing BRD7-knockout induced metastasis by depleting the CD8+ exhausted T cells is being assessed *in vivo*. **Conclusions:** Our novel functional genomic platform shall enable the identification of specific genes that enforce tumor dormancy or mediate metastatic reactivation of breast cancer. Furthermore, our findings that BRD7 is a suppressor of breast cancer lung metastasis and a predictive cancer biomarker could have major implications in the formulation of myriad therapeutic strategies for metastatic cancers. Taken together, we anticipate that our study could potentially bring about a paradigm shift in our understanding of how epigenetic regulators, like BRD7, mechanistically regulate breast cancer metastasis and reactivation by rewiring the tumor immune microenvironment.

1209 Evolving the Components of CRISPR-SaCas9 for ATTR Gene Therapy

Bang Wang[1], Xuejiao Piao[1], Miao Yu[2], Silvia Y. L. Mak[1], Zongli Zheng[2]

[1]GenEditBio Limited, HongKong SAR, China,[2]Ming Wai Lau Centre for Reparative Medicine, Karolinska Institutet, HongKong SAR, China

Transthyretin is encoded by the *TTR* gene and acts in tetramers to transport thyroxine and retinol (vitamin A) to different tissues via blood circulation system. Instability of the TTR tetramer may lead to polymerization, forming amyloid fibrils that deposes and accumulates within tissues, such as the peripheral nerves and heart, leading to transthyretin amyloidosis (ATTR) diseases. CRISPR-Cas9-based knock-out represents a promising potentially curative treatment by permanently knocking out the disease-causing TTR. However, off-targets across the human genome and associated genotoxicity are of great concerns in *in vivo* gene therapy. To explore the potential of Cas9 nucleases beyond the most used SpCas9 for high genome targeting precision, we systematically evaluated the performance of SaCas9, a smaller Cas nuclease (1,053 vs 1,368 a.a.) with a stricter PAM (NNGRRT vs NGG), on targeting *TTR* to outline a comprehensive view on its editing efficiency and off-target effect. We screened and engineered both components of CRISPR-SaCas9 (sgRNA and *SaCas9* mRNA). We first evaluated the on- and off-target effects of all guide candidates of SaCas9 across the *TTR* exonic regions, revealing two guides outperformed over others in on-target editing efficiency and in off-target profiles. To improve the editing potency of the two candidate guides, we chemically modified parts of ribonucleotides along the sgRNA with 2′-O-methylation and phosphorothioate linkage, which significantly improved the editing efficiency by nearly 10 folds. Moreover, we optimized the *cis*-elements (5'- and 3'-untranslation regions) of *SaCas9* mRNA to further enhance its expression and thus on-target editing efficiency. Because *SaCas9* mRNA should be first translated into protein, followed by assembly with sgRNA and

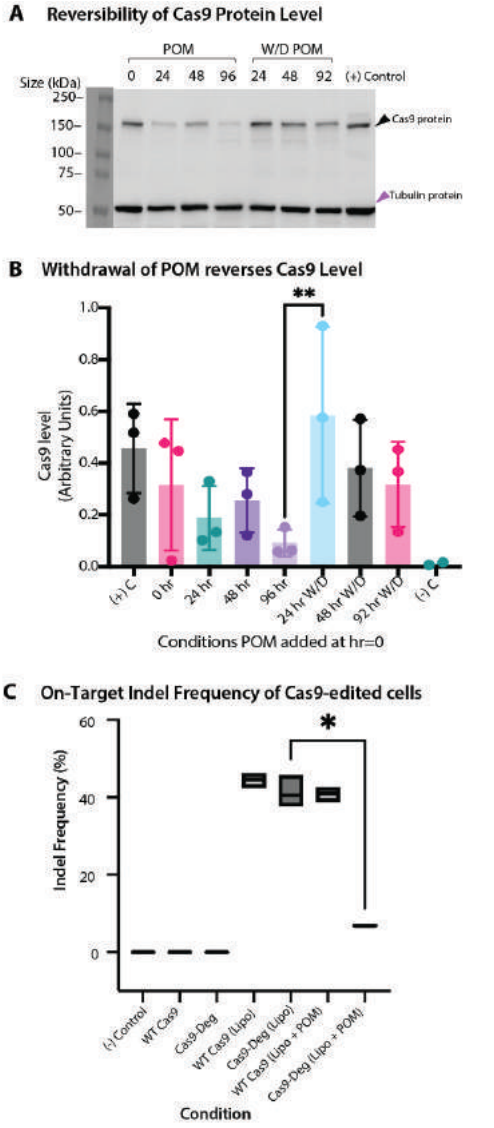
then imported into the nucleus, an optimal input ratio of sgRNA to mRNA would be critical to achieve an optimal final editing efficiency. We therefore assessed a range of sgRNA-to-mRNA cargo ratios. The results showed that a ratio of 1:4 increased the editing efficiency by ~50% as compared to a ratio of 1:1 at the DNA level, as well as in TTR protein reduction. Off-target effects were analyzed by using the GUIDE-Seq method, which showed no detectable off-targets even at super-saturating dose levels at concentrations over 15 folds to the 90% effective concentrations (EC90) in any of these experiments. The editing efficiency of the optimized components of CRISPR-*SaCas9* was further verified in primary human hepatocytes. Finally, the optimized cargo encapsulated by lipid nanoparticles was delivered into rat liver through intravenous infusion and achieved a robust *TTR* knock-out in liver as compared to existing editing efficiency mediated by CRISPR-SpCas9. Taken together, we comprehensively screened and evaluated multiple attributes of CRISPR-*SaCas9* and showed great potentials of using SaCas9 on the treatment of ATTR, with noteworthy distinction on no detectable off-targets at supersaturating doses. Our data provides a reference for the systematically delivered *SaCas9* mRNA with high precision and uncompromised efficiency in *in vivo* gene editing applications.

1210 Controlling CRISPR-Cas9 Genome Editing in Human Cells Using a Small-Molecule Inducible Degradation Strategy

Namita Khajanchi[1], Vrusha Chirayu Patel[1], Krishanu Saha[2]

[1]Biomedical Engineering, University of Wisconsin -- Madison, Madison, WI,[2]University of Wisconsin-Madison, Madison, WI

INTRODUCTION: CRISPR/Cas9 offers the advantage of targeting and cutting specific genes of interest with high precision. However, prolonged Cas9 activity has negative consequences such as off-target editing, genotoxicity, immunogenicity, and undesired on-target modifications. Current methods to control the CRISPR/Cas9 system include various small molecules, inhibitors, light and magnetic fields; however, these methods lack high-resolution temporal control over Cas9 activity *in vivo* and may leave behind residual active Cas9. Recent work has shown that a degron can be controlled by FDA-approved pomalidomide (POM). Here, we attach degrons to Cas9 and characterize the effectiveness of the degrons in degrading Cas9 and modifying the on- and off-target editing efficiency with POM. **METHODS:** Cas9-degron was inserted into human embryonic stem (H9s) and kidney (HEK293T) cells via lentiviral transduction. Varying amounts of POM were added to determine the optimal amount of drug that does not suppress cell growth or induce apoptosis. Studies were conducted to determine Cas9 protein levels once POM is added. To confirm that the degron does not hinder on-target editing efficiency, the AAVS1 Site 10 locus was targeted. DNA was extracted after two days, followed by PCR and Next Generation Sequencing. Replicates were lysed and Western Blotting was used to quantify protein. The RGEN and CRISPAltRations tool helped characterize on- and off-target editing. **RESULTS:** With the addition of POM, there is an overall decrease in Cas9-deg levels as shown by Western Blotting (Figure A). Withdrawing POM shows that Cas9 levels return within 24 hours, while a single dosage of POM can continuously degrade Cas9 protein up to 96 hours (Figure B). On-target editing efficiency (measured by indel frequency %) of wild-type (WT) Cas9 and Cas9-deg was similar (Figure C)—confirming that Cas9 activity is not hindered by the degron units. Adding POM to decrease Cas9 levels affected on-target editing efficiency significantly suggesting that Cas9-degron off-target editing activity will also decrease. **CONCLUSION:** The small molecule, POM, reversibly controls degron-engineered Cas9 protein levels as well as gene editing activity within human cells. Since, this small molecule inducer has been considered safe and is known to pass the blood-brain barrier, the system tested here has strong potential for reversible control of genome editing *in vivo* in many tissues, including the central nervous system.



A, B; Withdrawing POM reverses degradation of Cas9 protein. POM addition at hr 0 can have effects up to 96 hours and once POM is withdrawn ("W/D"), it only takes 24 hours for Cas9 levels to increase. Data represented with mean and SD, n = 3, p-values generated by mixed-effects analysis with Tukey's multiple comparisons test, against one another; ** for $p < 0.01$.

C; The degron does not hinder on-target Cas9 activity. Without a guide (No Lipo/No POM), there was no editing. Once the guide was added, both WT Cas9 and Cas9-deg had the same on-target editing efficiency. Inclusion of POM an hour before lipofecting the guide RNA shows that there is less editing for cells with Cas9-deg. Data represented with line at mean, n = 3 technical replicates per condition, p-values generated by Brown-Forsythe and Welch ANOVA tests against one another; * for $p < 0.05$.

1211 Small Volume Analytical Ultracentrifugation of AAV Vectors Based on the Band Sedimentation Velocity Method

Takahiro Maruno[1,2], Kentaro Ishii[2], Tetsuo Torisu[2], Susumu Uchiyama[2]

[1]U-Medico Inc., Suita, Japan,[2]Graduate School of Engineering, Osaka University, Suita, Japan

The accurate evaluation of particle size distribution contained in the adeno-associated virus (AAV) vector samples is one of the most important matters because the product-related impurities, including empty viral particles, and aggregates could be a possible cause of reducing the therapeutic efficacy. Based on this background, a lot of methodologies for the evaluation of particle size distribution of AAV vector were reported. Sedimentation velocity analytical ultracentrifugation (SV-AUC) is used to quantitatively evaluate the particle size distribution in solution by observing their sedimentation behavior in the centrifugal force field. Due to the high resolution of SV-AUC with respect to particle size in solution, SV-AUC is recognized as a gold standard for the evaluation of particle size distribution of AAV vectors. Moreover, SV-AUC with a multiwavelength detection enables the comprehensive characterization of the particles contained in AAV samples[1]. However, the relatively large amount of AAV vector sample (>10^{12} particles per experiment) in SV-AUC is a matter that needs to be overcome. In this study, we report an effective approach for size distribution analysis with a small amount of AAV vectors compared to SV-AUC[2]. A small amount of AAV vectors were used in band sedimentation analytical ultracentrifugation (BS-AUC). Compared with SV-AUC, BS-AUC could be performed with about 1/50 of the AAV vector amount (4×10^{10} particles). According to the limit of quantification of this BS-AUC, the quantifiable concentrations of empty viral particles and viral vector particles of AAV8-CMV-EGFP vector were 6×10^{11} particles/mL and 4×10^{11} particles/mL, respectively. These results demonstrated that our BS-AUC approach can compensate for the drawback in terms of the sample amount of SV-AUC. The method can be also applied to other viral vectors (adenovirus vectors, retrovirus vectors, lentivirus vectors, etc.) and is very useful for characterization of them, which are difficult to manufacture in large scale. We are in the process of customizing and evaluating band forming centerpiece, to achieve higher precision and robust analysis. We plan to introduce this topic in our presentation.

1212 Editing of a γ-Globin (*HBG1*/*HBG2*) cis-Regulatory Element in Human Hematopoietic Stem and Progenitor Cells Using Cas-CLOVER™ Technology Reactivates Fetal Hemoglobin

Haibin Xi, Nikki Nguyen, Kelli Korski, Patrick Hong, Blair Madison

Poseida Therapeutics, San Diego, CA

Current strategies to treat genetic diseases such as β-thalassemia and sickle cell disease include delivery of a therapeutic transgene, gene correction of the inherited mutation, or γ-globin (*HBG*) reactivation to express fetal hemoglobin (HbF). Many studies focusing on gene correction or addition of a therapeutic gene require usage of viral vectors (i.e., AAV) for delivery of DNA. However, AAV has shown to be cytotoxic in human hematopoietic stem and progenitor cells (HSPCs). CRISPR-Cas9 targeting of *BCL11A*, a potent HbF silencer, can lead to inhibition of the γ- to β-globin switching process. Targeting and knockout of BCL11A raises concerns that this transcription factor may have essential roles in native erythropoiesis and/or non-erythroid contexts. Therefore, the deletion of BCL11A-binding sequences in the proximity of *HBG* could be a more ideal target instead of complete knockout of *BCL11A*. De-repression of HbF increases γ-globin expression via deletion/mutation of the binding site for the BCL11A repressor in the *HBG* promoter. Here, we aim to reactivate γ-globin expression using the high-fidelity RNA-guided endonuclease, Cas-CLOVER, to target the BCL11A binding site in the *HBG* gene promoter. Cas-CLOVER has shown high efficiency in gene editing and low off-target activity compared to the CRISPR/Cas9 system. Four pairs of guide RNAs (gRNAs) targeting the distal and proximal BCL11A binding site were designed and tested in HSPCs. Three out of four gRNA pairs showed substantial editing. For all gRNA pairs, the editing was maintained in erythroid progenitors after edited HSPCs were differentiated to the erythroid lineage. For a selected pair, we observed robust editing at Day 4, and consistent maintenance of editing at Day 11 and Day 20, respectively, during erythropoiesis. Colony forming unit assays showed that colony distribution of CFU-GEMM, CFU-GM and BFU-E were similar between mock controls and edited cells. Thus, editing using Cas-CLOVER technology does not affect HSPC multi-lineage colony forming capabilities. Finally, in vitro erythroid differentiation of edited HSPCs showed a 4 to 9-fold increase in γ-globin expression over unedited controls detected by RT-qPCR. Cas-CLOVER editing of a γ-globin/*HBG* cis-regulatory element can enhance HbF activation, which could potentially serve as an efficient therapeutic strategy for β-hemoglobinopathies.

1213 RNA Virus Based Episomal Vector for Highly Efficient Genetic Engineering of Human Mesenchymal Stromal Cells

Ryo Komorizono, Shima Yoshizumi, Miya Kawanaka, Keizo Tomonaga

Institute for Life and Medical Sciences, Kyoto University, Kyoto, Japan

Introduction Although cell therapies using stem cells for the treatment of genetic disorders have been highly guaranteed to be safe in clinical studies, they often fail to demonstrate sufficient drug

efficacy. In recent years, novel ex vivo gene cell therapeutic strategies have come into the spotlight, in which the cells to be transplanted are modified in their properties by genetic engineering techniques to enhance their drug efficacy and cell proliferative potential. Therefore, there is a need for genetic engineering technology specifically for stem cell modification. We have demonstrated that the RNA virus-based episomal vector "REVec" has high transduction efficiency in mesenchymal stromal cells (MSC) and is a long-term genetic modification tool without genome integration to the host. **Methods** The transduction efficiencies of the lentiviral vector and REVec were compared by measuring immunofluorescence assay and luciferase activity after the transduction of each vector encoding GFP and luciferase into human MSCs at the same copy number. **Results** The transduction efficiency of REVec into MSCs was approximately 2-fold higher and the gene expression level in transduced MSCs was 1.5-fold higher than those of CMV promoter-driven lentiviral vector. The amount of REVec-derived transgene DNA was quantified using extracted genomic DNA of REVec-transduced MSCs and found to be below the detection limit compared to lentiviral vectors. REVec could also be transduced into bone marrow, umbilical cord blood, and adipose tissue-derived MSCs, and the gene expression level was maintained for at least three weeks after transduction in vitro. **Conclusion** Here, the novel viral vector REVec was shown to be a superior genetic transduction tool for stem cells compared to competing technologies. The high efficiency of gene transduction has significant industrial advantages, and high gene expression levels and persistence of expression will have a direct impact on the medicinal efficacy of gene cell therapies. REVec has the potential to be a standard vector for ex vivo gene cell therapeutics using genetically engineered stem cells.

1214 Evaluation of Gene Transfer Efficiency in a Mild Model of Dystrophic Muscle Disorder Performed by Machine Learning and Linear Discriminant Analysis

Anthony Y. B. Brureau, Carinne Roudaut, Marine Faivre, Daniel Stockholm, Isabelle Richard

GENETHON, Evry, France

Evaluation of gene therapy efficiency and the reversibility of the pathophysiological events depend on the sensitivity and specificity of the assessment to characterize the experimental model. In fact, one of the issues of translational research is the lack of prediction for some animal models. For example, multiple models of the Limb-girdle muscular dystrophy with calpain 3 deficiency (LGMD-R1) were created whereas no one can mimic the severity of the human disease. Multiple pieces of evidence showed that machine learning methods applying in image analysis could improve the efficiency and the reproducibility of phenotype evaluation. Furthermore, a supervised training method as Linear Discriminant Analysis (LDA) aimed to optimize the variability between control groups (KO-C3 and WT littermate), and to decrease the variability in each control group, by transforming the data and decreasing the number of dimensions and can be used to improve the control groups discrimination, and finally could help to increase the sensitivity to evaluate gene therapy efficiency. Here we aimed to use this approach, to evaluate a mild-phenotype rat model of LGMD-R1, and to evaluate the efficiency of gene therapy strategy. By using machine learning to first increase the reproducibility in the measurement of the histological dystrophic biomarkers, combining to functional data, and applying a supervised training method as LDA, we hypothesized that we could define a minimal efficacy dose of an AAV vector, to alleviate dystrophic phenotype in a mild phenotype KO-C3 rat model. For this purpose, at one (1) month of age, the KO-C3 rat model was injected with an AAV vector (in a dose response manner) to transfer the human calpain 3 gene into skeletal muscles. Five (5) months later, an *in vitro,* functional analysis was performed on muscle by measuring the isometric contractile properties of the muscle, and the Tetanus isometric contractions. Machine learning methods on histopathological images were used to evaluate the degeneration and regeneration of muscle fibers, the inflammation, and the fibrosis. Those data were combined with the functional data from control animals in a multidimensional dataset and transformed by LDA. After a cross-validation, and the selection of the accurate variables, the model was used to predict the efficiency of the gene transfer strategy of calpain-3. The results showed that the LDA was able to well discriminate the control animals by combining functional and histological data, in a mild-phenotype model of dystrophic disease. The efficiency of the gene transfer therapy with an AAV vector strategy was also assayed and thanks to the LDA, it was possible to predict a minimal effective dose. This study showed that the histopathological hallmarks of the disease evaluated by automatic classifier algorithm coupled to functional data and used to train a supervised LDA model allow to optimize the dystrophic features analysis and could assay the efficacy of a gene transfer strategy.

1215 Scale-Up of Suspension 293T/17-Based Cells for GMP Manufacture of AAV

Bryan A. Piras, Baochang Fan, Adriana Barba-Montoya, Timothy Lockey, Frank Fazio

St. Jude Children's Research Hospital, Memphis, TN

Production of AAV for early-phase clinical use requires manufacture utilizing hundreds to thousands of liters of upstream cell culture. Production facilities for early-phase trials have often relied upon adherent cell-based processes, though suspension cells offer greater flexibility and far superior scalability. We developed a transfection-based process using 293T/17 cells adapted in-house to suspension culture. Cells were cultured in 5 or 200 L bioreactors and transfected using TransIT-VirusGen. Two days post-transfection, cell lysis was performed using high-pressure homogenization and the combined media and lysate were clarified via depth filtration. Filtrate was loaded directly onto a POROS AAVX affinity column, after which additional impurities were removed via hydrophobic interaction on a Sartobind Phenyl column. After buffer exchange, anion exchange chromatography on a BIA CIM QA monolith was utilized to enrich genome-containing AAV particles. For GMP manufacture of Phase I/II material, four 200 L bioreactor runs were purified through anion exchange chromatography, buffer exchanged to PBS, formulated in 0.25% recombinant human albumin, and frozen. These four runs were subsequently combined into a pooled drug substance, diluted to a target concentration, and filled into 10 mL glass vials. Average titers across four 5 L runs were $1.74x10^{11}$vg/mL and $8.20x10^{11}$ capsids/mL, while average titers across five 200 L runs were $1.65x10^{11}$ vg/mL and $8.39x10^{11}$capsids/mL. Other

results, including cell growth and impurities, were consistent across 5 L and 200 L scales and will be presented along with several challenges related to scale-up and manufacture.

1216 A Rhabdovirus-Negative Sf-RVN® Platform is a Safer BEVS Alternative for Production of Recombinant Protein and AAV

Sandra McNorton[1], Charlotte Javalet[2]

[1]Upstream R&D Media Development, MilliporeSigma, Olathe, KS,[2]Product Manager, Merck KGaA, Meylan, France

The Baculovirus Expression Vector System (BEVS) is a powerful eucaryotic vector system and has been used for more than thirty years as a research tool. Nowadays, the BEVS is being utilized by biopharmaceutical companies to produce recombinant adeno-associated vectors (AAV) to treat genetic diseases. The resurgence of gene therapies is providing lifesaving options to patients with otherwise untreatable diseases, leading to increased demand for large amounts of high-quality viral vectors. *Spodoptera frugiperda* (Sf) cell lines are widely used as hosts for BEVS. However, the majority of Sf9 and Sf21 cell lines contain a rhabdovirus which is considered a process contaminant and must be eliminated during the process. To improve the safety profile of the BEVS production method, we developed a high performant Sf-rhabdovirus-negative (Sf-RVN®) platform, composed of an Sf9 rhabdovirus-free cell line with an optimized chemically defined medium. Productivity of reporter protein was analyzed using the Sf-RVN® Platform as well as the production of AAV2 using the 2 baculoviruses system. Data shows that this rhabdovirus-negative platform provides increased productivity. Hence, the Sf-RVN® Platform is a performant rhabdovirus-free BEVS alternative to produce recombinant protein and AAV and enhances risk mitigation.

1217 A Novel AAV8 Capsid Variant Enabling Potent Ocular Gene Delivery in Rabbit and a Laser Induced CNV NHP Model

Qiang Zheng[1], Shuang Luo[1], Hao Jiang[1], Qingwei Li[1], Yingfei Qin[1], Fan Yang[1], Aibing Liu[1], Jing Li[1], Avner Ingerman[2], Anna Oughton[2], Shawn Patrick Shearn[2], Qing Xie[1], Xiao Ke*[1,3]

[1]Chengdu Origen Biotechnology Co., Ltd, Chengdu, China,[2]Vanotech Ltd, Rockaway, NJ,[3]Chengdu Kanghong Pharmaceuticals Group Co Ltd, Chengdu, China

Suprachoroidal space (SCS) injection is a simple and efficient technology that delivers medication materials directly into the eye, and can be done in an out-patient setting. Recombinant adeno-associated viruses (rAAVs) are emerging as the most widely used *in vivo* vehicles to deliver a targeted therapeutic gene cassette into tissues. Tropism and transduction efficiency of rAAVs greatly influence the therapeutic outcomes. The purpose of the current study is to find a new AAV capsid that can efficiently transduce retinal tissues by SCS injection. In the present study, a series of engineered vectors were generated by modifying the VP3-VIII region of a natural prototypical AAV8 capsid using a rational design method. A new capsid variant candidate v128 was selected to perform a biodistribution assay in rabbit eyes (Figure 1A-B). The transduction potency of this candidate was further evaluated in a laser-induced CNV non-human primates (NHPs) model. In a side-by-side study, the v128 candidate displayed similar tissue tropism with its prototypical AAV8 capsid vector, but has enhanced transduction efficiency for retinal pigment epithelium (RPE) and photoreceptor cells after SCS injection in rabbit eyes (Fig.1 A, B). The v128 vector has a 51.4-71.8 fold higher transduction efficiency as compared to prototype AAV8 as determined by transgene (mCherry) copy number assay (Figure 1C). As v128 candidate efficiency was determined, a further experiment is described to evaluate therapeutic potency of the candidate in a laser-induced CNV NHP model. AAV vectors carrying an anti-VEGF transgene (Aflibercept) were produced with the v128 capsid and the prototypical AAV8 capsid respectively. Each vector was injected into the SCS of the NHP eyes at a targeted dose of 1E12 vg/eye. At the evaluation timepoint, 42-days post injection, a higher concentration of transgene was found in the v128 treated NHP retina, at a level of 4056 ng/g (oculus sinister, OS) and 2112 ng/g (oculus dextrus, OD) respectively compared to prototype AAV8, and further there was considerable transgene expression also found in other ocular tissues including: aqueous humor, choroid, conjunctiva, iris/ciliary body, sclera and vitreous. In the control AAV8 group, transgene expression in NHP retina was undetectable for both eyes, and the only tissue with transgene expression was iris/ciliary body, with concentration of 39.12 ng/g (OS) and 52.8 ng/g (OD) respectively. The initial data indicates the candidate v128 capsid has demonstrated enhanced transduction efficiency in animal ocular tissues, especially the retina, compared to its prototypical capsid AAV8. The novel capsid warrants further exploration as a potential gene delivery vehicle to treat ocular disorders of the retina.

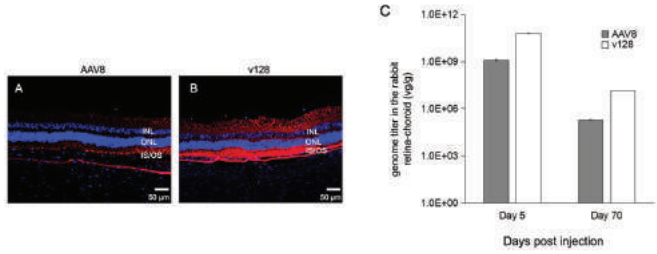

Figure 1. v128 variant shows enhanced transduction efficiency in rabbits' ocular tissues. (A-B) Immunofluorescence images of the rabbit retinal layer. 1.25E11 vg/eye of AAV8-mCherry or v128-mCherry was injected into rabbit suprachoroidal space. 21-days post injection animals were sacrificed, and the retinas were isolated. Images were taken by a confocal fluorescence microscope. (C) Genome copy numbers in AAV treated rabbits' retina-choroid tissues at day-5 and day-70.

1218 High-Throughput Arrayed Screening of Logic-Gated CARs Enables the Selection of Candidates for ccRCC with Optimal Potency and Fidelity Traits

Jamie J. Thomas, Nishant Mehta, Edward Yashin, Andrea Fua, Johnny Li, Jon Chen, Laura Lim, Mary Chua, Andrew Cardozo, Marian Sandoval, Duy Nguyen, Ziyan Hong, Jimmy Wu, Cate Sue, Gustavo Guzman, Li Wang, Sofia Kyriazopoulou Panagiotopoulou, Sophie Xu, Angela Boroughs, W. Nicholas Haining

ArsenalBio, South San Francisco, CA

The development of clinically effective CAR-T cell products for solid tumors will require substantial cell engineering to confer sufficient specificity, potency, and persistence. Advances in genome engineering and synthetic biology have provided an increasingly complex set of features that can be introduced into CAR-T cells to augment their function. However, combining multiple features may result in unpredictable negative interactions between components. Here, we report the use of high-throughput screening to optimize the design of a highly-engineered Integrated Circuit T Cell (ICT) product for the treatment of clear cell renal cell carcinoma (ccRCC). ICT cells are CAR-T cells that contain an AND logic gate requiring two antigens to be present to trigger tumor cell killing together with multiple enhancement modules. First, to create the logic gate we generated hundreds of novel scFv and VH/VHH binders targeting PSMA (as a priming target) and CA9 (as a cytolytic target) via two parallel de novo binder discovery efforts: 1) transgenic mice immunizations and 2) internally-developed phage display panning campaigns. Two independent arrayed screens with 500 PSMA prime receptors (PrimeRTM) and 750 CA9 CARs were conducted to find PrimeRs with high inducibility and CARs with strong on-target potency. A fully-automated, end-to-end workflow was used to conduct each arrayed screen with the PrimeR screen evaluating PSMA binders with a fixed CAR binder and the CAR screen evaluating CA9 binders with a fixed PrimeR. Non-viral editing techniques were used to electroporate primary CD4/CD8 cells and robotic handlers were used to set up co-cultures. Lead nominations were conducted based on the desired criteria that 1) PrimeR is expressed constitutively and can induce CAR in the presence of PSMA, 2) CAR can be induced and remain stable on the surface, 3) does not elicit a response in the presence of a single-antigen and 4) CAR-dependent binding elicit strong activity that is comparable to endogenous levels of CA9.From these screens, the top 25 PSMA PrimeRs and 20 CA9 CARs were combined with an shRNA cassette for targeted knockdowns along with two variations of a persistence module. We used the same automated workflow to perform an integrated screen of the resulting 1,000 member library in T cells engineered from four human donors. Circuit specificity and potency were assessed by flow and cytokine secretion and resistance to exhaustion was assessed in a seven day killing assay. Although the library was built from components that functioned well independently, we found that when combined, many of the circuits displayed suboptimal function. Integrated screening identified 20 variants that each far exceeded the performance of a small set of initial prototypes built from top selections of individual screens. The final candidates are significantly superior to constitutive CAR-T cells in a long term killing assay, show potent cytotoxicity of low expressing antigen lines, and display background levels of cytotoxicity against single antigen targets. Engineering multiple features into T cell products is limited by unpredictable negative interactions between components. We have overcome this limitation by using high-throughput screening which generated development-ready candidates for ccRCC with finely tuned desirability criteria in <18 months.

1219 Application of ADAR-Mediated RNA Editing to Upregulate Gene Expression by Modulating Protein-Protein, Protein-RNA or RNA-RNA Interactions

Chikdu Shivalila, Ian Harding, Prashant Monian, Genliang Lu, Keith Bowman, Michael Byrne, Arindom Chatterjee, Jigar Desai, Jason Dufresne, Frank Favaloro, Stephen Friend, Jack Godfrey, Naoki Iwamoto, Jayakanthan Kumarasamy, Pachamuthu Kandasamy, Tomomi Kawamoto, Anthony Lamattina, Gina Lein, Amber Lindsey, Richard Looby, Leah McCarthy, Andrew McGlynn, Allison Molski, Qianli Pan, Erin Purcell-Estabrook, Jeff Rossi, Stephany Standley, Alexandra Walen, Hailin Yang, Yuan Yin, H. Yu, Paloma H. Giangrande, Chandra Vargeese

Wave Life Sciences, Cambridge, MA

AIMers—chemically modified oligonucleotides in which the chiral configurations of backbone linkages are precisely controlled at each position—direct sequence-specific adenine (A) to inosine (I)/guanine (G) RNA editing using endogenous ADAR enzymes. In addition to correcting disease-causing mutations, AIMers can be applied to modulate protein-protein, protein-RNA, and RNA-RNA interactions, thereby expanding the scope of human diseases that can potentially be addressed with this technology. We present AIMers designed to modulate the NRF2-KEAP1 protein-protein interaction system, a conserved intracellular defense pathway to counter cellular oxidative stress. NRF2 is a transcriptional regulator of antioxidant and metabolic genes that is negatively regulated through direct interaction with KEAP1, where KEAP1 sequesters NRF2 in the cytoplasm, promoting its degradation. By disrupting this interaction, AIMers activate NRF2-dependent gene expression. We designed AIMers to modify amino acids at the interface between KEAP1 and NRF2. We show AIMers direct up to 80% editing of NRF2 or KEAP1 transcripts in multiple human and mouse cell types *in vitro* and show that editing leads to dose-dependent activation of NRF2-dependent gene expression. We applied AIMers *in vivo* in mice expressing human ADAR1 and observed ≥40% transcript editing and activation of NRF2-dependent gene expression in the liver. We also present AIMers designed to alter gene expression by modifying regulatory elements in RNA that mediate protein-RNA or RNA-RNA interactions. Specific structural or sequence motifs that mediate these intermolecular interactions impact RNA processing and stability. We have designed AIMers to modify regulatory RNA elements with the aim of increasing the stability of the associated transcripts. By editing RNAs encoding multiple metabolic and immune proteins, we demonstrate that AIMers that modify regulatory RNA elements can increase mRNA expression 2-15-fold *in vitro* in cultured cells. We also show GalNAc-conjugated AIMers that lead to 40-60%

editing of these RNA regulatory elements in the mouse liver result in a corresponding ~5-fold increase in mRNA expression in liver and protein expression in serum one-week after treatment. Together, these data provide proof-of-concept that AIMers can modulate protein-protein, protein-RNA, and RNA-RNA interactions to upregulate gene expression *in vitro* and in mice.

1220 The OMNI™ Panel of Novel Engineered Nucleases Unlocks the Full Potential of Genome Editing

Liat Rockah, Malka Aker, Michal Sharabi Schwager, Noa Oded Elkayam, Nurit Meron, Ariel Gispan, Ella Segal, Bar Ben Baruch, Milit Marom, Tali Pechenick Jowers, Rachel Diamant, Rafi Emmanuel, Idit Buch, Lior Izhar

Emendo Biotherapeutics, Rehovot, Israel

Gene editing is revolutionizing molecular therapeutics. However, a key challenge in realizing the full clinical potential of this technology is the narrow repertoire of protospacer adjacent motif (PAM) sequences used by commonly applied nucleases. This restricted PAM selection limits the range of genomic targets accessible for editing and, in turn, limits the range of treatable diseases. While NGG PAM nucleases have proven useful, NGG PAM coverage across the total area of genes in the human genome is only ~5%, leaving many therapeutic relevant sites without an NGG PAM in the required editing window. Wide genome accessibility is necessary to access every potential target gene and cut site. Our solution to this challenge is based on the recognition that different nucleases utilize widely varied PAMs differing in sequence and length. With the aim of discovering novel nucleases with alternative PAM usage we have developed a dual platform technology combining a discovery pipeline and cutting-edge protein-engineering capabilities, supported by extensive computational and machine learning tools. Using this powerful platform, we have generated a panel of novel OMNI™ nucleases that unlock the full potential of genome editing. These Type II nucleases, used in our own clinical programs, are diverse in size and compatible with all delivery modalities. Importantly, our OMNI™ repertoire increases PAM usage diversity to approximately 79% gene coverage. Our engineered highly active and highly specific variants enable eliminating off-target effect and performing allele-specific editing. We are currently testing our nucleases in preclinical programs across various conditions, including severe congenital neutropenia, familial hypercholesterolemia, and retinal degenerative diseases. Our unique approach allows us to make any gene targetable, transforming the current landscape of genetic medicine.

1221 E1-Transformed BHK Cell Lines for Helper Virus-Free AAV Production Using Triple Transfection

James W. Brown, Santo Anto, Amber Chevalier Plambeck, Andrzej K. Noyszewski, John Ballantyne, Michael Chambers, Alex Deiulio, Erica Kelly Venberg, Jagadish Loganathan

Agathos Biologics, Fargo, ND

Adeno-associated virus (AAV) is currently the most researched viral vector for use in gene therapy. For several decades, human embryonic kidney (HEK293) cells have been the only adenovirus E1-complementing mammalian cell line suitable to produce adeno-associated viral vectors of different serotypes via triple transfection. There is a need for improved methods to address yield, scalability, and ethical concerns regarding rAAV production. To address this demand, we have developed a new cell line derived from baby hamster kidney cells (BHK-21) transformed with a fragment of the Ad5 sequence. We demonstrated this transformed BHK-21 cell line, BHK-[wt E1] stably expresses the E1 proteins. BHK-[wt E1] produced recombinant AAV by triple transfection and was confirmed based on yield, detection of viral proteins, and infectivity. FIG. 1 shows the general scheme of the experiments, and FIG. 2 shows rAAV2 viral genomes from transformed polyclonal BHK-[wt E1] cells compared to parental BHK cells untransformed (measured value below limit of detection) after triple transfection. These data demonstrate the proof of concept for this approach, and continued development and optimization of these cell lines should improve their properties. In addition, for isolating individual clones from a single cell, we used high-content imaging system to identify high-quality and pure clones for rAAV producing cell lines. The successful transformation of BHK cells as a new E1 complementing cell line and subsequent expression of high levels of E1 are important factors for rAAV production. We also discuss other strategies for creating E1-complementing cell lines using different E1 sequences. BHK-[wt E1] and other E1-complementing cell lines based on BHK may provide advantages in applications where HEK293 and similar cells are used.

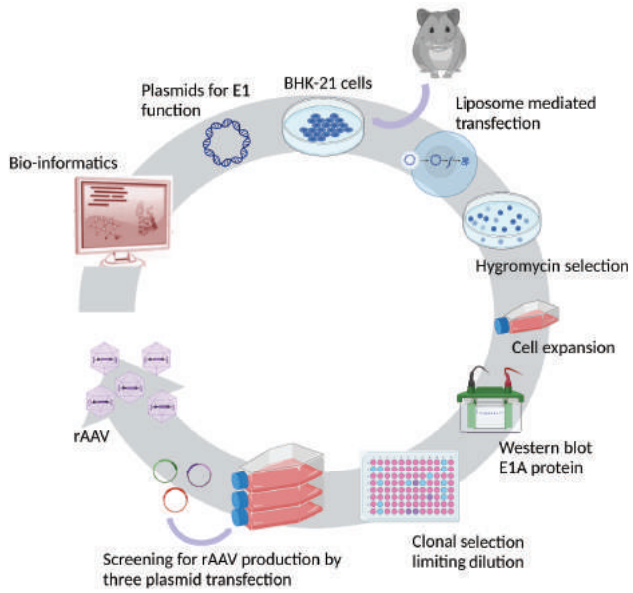

FIG. 1 Process steps for establishing and assessing BHK-21 cells for rAAV production.

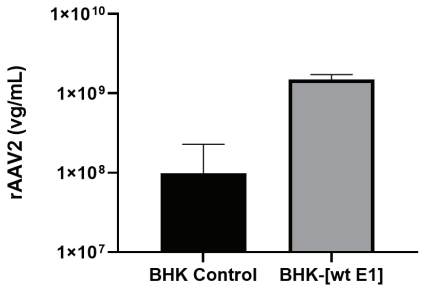

FIG. 2 Digital PCR (QIAcuity, Qiagen) measurements of rAAV2 viral genomes. BHK-[wt E1] $1.5x10^9$ +/- $2.20x10^8$, BHK Control below level of detection.

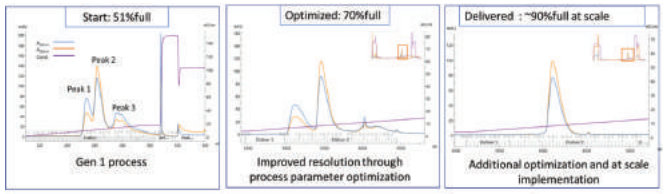
1222 Pushing the Boundaries of AAV Empty Capsid Removal: Challenges and Solutions for Resolving Half-Loaded Capsids Using Anion Exchange Chromatography

Xiaotong Fu, Richard Gyamfi Atta, Colin Haws, John F. Kerwin

Resilience, Waltham, MA

Recombinant adeno-associated virus (rAAV) vectors have been developed as one of the most promising gene delivery candidates due to their high transduction efficacy, good safety profile, and unique tropism. However, the drug product quality impact from empty capsids remains inconclusive and requires additional downstream process capability to remove them. Though the technology of using anion-exchange chromatography (AEX) to separate empty capsids from the genome containing capsids has made significant progress in recent years, achieving good resolutions between different AAV subpopulations are still challenging due to the minute differences in their charge profiles. This becomes particularly problematic when the encapsidated gene sequence is not designed to maximize AAV load capacity. In this work, we presented a study to develop a robust and effective AEX process for an AAV product with half payload (2.3kb), where the regular AEX protocols failed to resolve the empty and genome-containing capsids. In this study, we evaluated several critical parameters that can potentially improve AEX resolution, including buffer matrices, MgCl2 concentration, column loadings, peak fractionations, etc. By combining multiple optimized parameters, the process was able to improve the %full from 50%, the original AEX process, to 90+%. Comparable %full results were reported using multiple analytical tools, including analytical ultracentrifugation(AUC), mass photometry (MP), and charge density mass spectrometry (CDMS). Full characterization of the elution profile was also conducted to understand the distribution of AAV subpopulations during AEX elution, including empty, partially-filled, full-length genome containing (2.3kb), and over-packaged (2.3+kb) capsids. The study was wrapped up with a scalability demonstration from bench-scale to pilot-scale, along with a reproducible, fully automated peak fractionation strategy for large-scale manufacturing.



1223 The Role of Natural Killer Cells During Adenovirus Infection: Implications for Adenovirus Based NK-cell Therapy

Luca Scarsella[1], Wenli Zhang[1], Serge C. Thal[2], Anja Ehrhardt[3], Malik Aydin[1]

[1]Human Medicine, Faculty of Health, Witten/Herdecke University, Witten, Germany,[2]Department of Anesthesiology, Helios University Hospital Wuppertal, Witten/Herdecke University, Wuppertal, Germany,[3]Private University Witten/Herdecke, Witten, Germany

Natural killer (NK) cells have been shown to exert a robust anti-viral and -tumor activity and were successfully applied in CAR-based cellular immunotherapy using different vectors to engineer these cells. Although there are hints in the literature that commonly used adenovirus (Ad) type 5-based vectors carrying an Ad35 or Ad37 fiber can transduce NK cells, a systemic analysis of a broad spectrum of human Ads on primary NK cells is lacking. Therefore, we focused on identifying novel Ad candidates for efficient NK cell transduction and aimed at analyzing the role of NK cells during Ad infection. To address these questions, we studied the transduction efficiencies of 21 recombinant human Ad types derived from different Ad species in peripheral mononuclear blood cells (PBMCs) and isolated NK cells derived from healthy donors. All analyzed viruses contained a dual-reporter cassette expressing green-fluorescent protein and Nano-luciferase to monitor transduction rates. We found that Ad35 from species B using CD46 as major cell entry receptor and Ad37 from species D using GD1a glycan as entry receptor revealed highest transduction efficiencies in PBMCs derived from healthy donors. To understand the role of NK cells during Ad infection, we performed co-culture experiments using primary NK cells, which were co-cultured with A549 lung cancer cells. Here, we infected A549 cells with 3, 30 and 300 virus particles per cell (VPC) for four hours with Ad35 and

Ad37, removed the virus from the culture medium and subsequently added primary NK cells for 24 hours. Quantitative PCR analysis revealed that 300 VPC showed highest transduction efficiencies in A549 cells compared to groups treated with lower VPC. Focusing on the hypothesis whether virus progeny from A549 cells results in infection of co-cultured NK cells, we performed RT-qPCR for detection of Ad-derived transgene expression in NK cells. Preliminary results revealed that NK cells were successfully infected. In the next steps, we plan to analyze the production of cytokines in NK cells in the presence of Ad infection. Furthermore, the transcriptome of these NK cells will provide more information on cell-cell interaction during Ad infection, and will enable to identify a new panel of distinct changes in NK cells upon Ad infection. We believe that this information will help to develop gene therapeutic vectors to treat orphan diseases in the future.

1224 Next-Generation Microfluidic Technology for Gene-Editing in Human Primary T Cells Using CRISPR-Cas9

Ailin M. Goff, Struan Bourke, Ockchul Kim, Ian Sicher, Alexander Alexeev, Todd Sulchek, Alla Zamarevya, Sewoon Han, Chih-Wen Ni

CellFE, Alameda, CA

Introduction: The exploitation of CRISPR-Cas9 ribonucleoprotein (RNP) complexes for gene editing is rapidly driving the development of non-viral gene therapies. Current trends in cell and gene therapy workflows are reliant on viral transduction to efficiently deliver genetic material. However, CRISPR-Cas9 transfected cell therapies can result in lower immunogenicity and fewer off-target effects as well as reduce manufacturing costs. CRISPR knockout (KO) is achieved through the complexation of Cas9 nucleases in combination with small single-guide (sg) RNAs to selectively target genes through site-specific recognition. For CRISPR knock-in (KI), an additional DNA donor component is included such as; single-stranded DNA, double-stranded DNA, or a plasmid, that can be added to deliver a gene of interest to the target site with limited off-target effects. We developed a workflow using microfluidic technology to effectively deliver both RNP and a DNA donor template to perform permanent genetic edits in T cells. The technology uses the unique properties of fast biomechanical deformations to rapidly edit cells while maintaining their capacity to expand and proliferate. By using the current workflow, we achieve over 15% knock-in efficiency in both Jurkat and human primary T-cells while maintaining high viability. **Materials and Methods:** In our concept validation study, we deliver CRISPR-Cas9 and donor DNA to both Jurkat cells and human primary T cells. Frozen cells are thawed two days prior to transfection, and human primary T cells are activated with the chemical activator, TransACT. At 48 hours post-activation, we use our novel microfluidic platform to co-deliver linearized double-stranded DNA with CRISPR-Cas9 RNP complexes. Our device has a high processing capacity, capable of transfecting high-cell-density samples at a rapid rate. For knock-in transfection, we process 1.5 million cells in 30 µL of native cell media through each microfluidic consumable, a process that occurs in under 1 second. T cells are directly cultured, with no need for new media exchanges, for two days, and total CRISPR events (including both knockout and knock-in results) are gathered via flow cytometry, as well as quantitative data read out through fluorescence microscopy. The cells are kept in culture for five days post-transfection to monitor the proliferation of each sample and the durability of transgene expression. **Results:** Through the homology-directed repair (HDR) pathway, we inserted an EGFP transgene into several loci; including a ubiquitously expressed target, *RAB11a*(>15% knock-in), and the T cell receptor protein, *TRAC* (>10% knock-in). Knockout data at the *TRAC* locus shows 60-80% knockout, leading to a total gene-editing efficiency of upwards of 90% using our microfluidic process. The results show minimal impact on cell health after processing, with recovery two days post-transfection (>80% viability) and no impact on proliferation. **Conclusions:** Gene therapy manufacturing is labor and time intensive, but our high processing parameters allow for rapid manufacturing. Additionally, we are able to achieve high gene editing efficiency with low cytotoxicity and low impacts on cell functionality. Our microfluidic technology represents an exciting future for non-viral gene therapy with several applications to cell therapy manufacturing.

1225 Total Lowering of HTT Using Vectorized Antisense Oligonucleotides for the Treatment of Huntington's Disease

Johanna Adams[1], Martin Goulet[1], Shyam Ramachandran[1], Bradford Elmer[1], Christian Mueller[2]

[1]Sanofi, Waltham, MA,[2]Sanofi Genzyme, Framingham, MA

Huntington's disease (HD) is a fatal, monogenic neurodegenerative disease that affects between 5-17 of every 100,000 persons. Expanded trinucleotide repeats in the huntingtin gene (HTT) confer a toxic gain-of-function that causes progressive motor, cognitive and neuropsychiatric impairment for which there is currently no disease modifying treatment. Partial suppression of HTT in the brain has been demonstrated to be both safe and efficacious in animal models of HD, providing proof-of-concept for a HTT lowering therapeutic strategy. Vectorized antisense oligonucleotides (vASO) act at the transcriptional level to reduce levels of target RNA and can be expressed from adeno-associated viral (AAV) vectors for long-term target engagement. Here, we have designed and leveraged a novel vASO platform to achieve significant *in vitro* reduction of total endogenous HTT mRNA. Vectorization of ASOs involves the initial incorporation of an ASO sequence into a modified U7 snRNP (U7smOpt) sequence for nuclear localization. We first designed a novel tandem-repeat construct containing multiple copies of U7smOpt and validated this expression construct with published SOD1-targeting ASO sequences. We then generated a library of constructs expressing individual ASO sequences that collectively tiles across a target HTT exon and 100nt into its flanking introns. As these ASOs were designed to generate target knockdown by inducing exon skipping in a manner that triggers nonsense-mediated decay of the transcript, we designed and validated a novel assay for specific and sensitive multiplexed quantification of exon-skipped and total HTT transcript. The ASO library was transfected into HeLa cells that express endogenous HTT. RNA was isolated 48 hours post-transfection and assayed for exon-skipped and total HTT transcript levels. Several individual vASO sequences yielded significant target exon skipping and HTT transcript knockdown, with maximum exon skipping of 20% and maximum mRNA target knockdown of 32% relative to a control. As expected, the incidence of exon skipping events and total transcript knockdown is linked. Skipping events and transcript knockdown also appear to be caused

by ASO sequences largely targeting within the exon, with the highest efficacy seen for sequences tiling 20-30nt from the splice junctions. These results clearly demonstrate the vASO platform as a viable strategy for HTT lowering and can inform design strategies for other targets to streamline early discovery screening.

1226 Modulation of Loss of Neuromuscular Junctions in the Muscle of ALS Mice

Stefano Cagnin[1], Raphael Severino Bonadio[1], Francesco Chemello[1], Caterina Paggion[2], Giulia Zanetti[2], Maria Lina Massimino[3], Marco Pirazzini[2], Alessandro Bertoli[1]

[1]Department of Biology, University of Padova, Padova, Italy,[2]Department of Biomedical Science, University of Padova, Padova, Italy,[3]CNR, University of Padova, Padova, Italy

Amyotrophic Lateral Sclerosis (ALS) is the most common adult-onset motor neuron (MN) disease whose causes remain largely unknown and whose therapeutic options are ineffective in the long term. Hallmark of ALS is the selective and progressive degeneration of lower and upper MNs, which leads to spasticity, weakness, and muscle atrophy. Several studies suggest that non-coding RNAs are critical for ALS onset and progression. Most of studies of ALS are neuro-centric assuming that MN disfunctions are the main origin of the disease and muscle alterations are consequences. Growing evidence, however, suggest that molecular alterations in muscle fibers in the presymptomatic phase can trigger ALS pathology. However, there is still a huge gap in the knowledge about the molecular mechanisms that compromise muscle synapses and consequently MNs. To fulfil this gap, we analyzed the non-coding and coding differentially expressed genes of skeletal muscle from SOD1*G93A mice, an established model for ALS studies. We identified a signature composed by 3 miRNAs (miR-152, miR-193a, and miR-193b) that was activated in pre-symptomatic conditions of ALS and that is involved in the development, maintenance, and functionality of neuromuscular junction (NMJ). Our analysis on muscles of ALS mouse model revealed an aberrant expression of genes that encodes for acetylcholine receptors (AChRs) subunits and the results strongly suggest that the 3 miRNAs are involved in the adult-to-fetal switch of AChRs isoforms in ALS. In vitro assays confirmed that the miRNAs indeed bind the 3'UTR of target genes and effectively induce their degradation. In vivo functional assays corroborate the involvement of miR-152, miR-193a, and miR-193b in the onset of myopathies. The overexpression of the pooled miRNAs in healthy mice induced loss of muscle mass and weight reduction. The mechanisms responsible for muscle atrophy induction were also investigated. High levels of miR-152, miR-193a, and miR-193b induce the impairment of synaptic transmissions and disrupt NMJ functioning. Interestingly, we also observed the fast-to-slow myofiber shift phenomenon as a consequence of the treatment. Altogether, these results suggest that miR-152, miR-193a, and miR-193b could possibly trigger ALS, since their aberrant expression occurs in the early-stage disease. For this reason we try to modulate the expression of the three miRNAs in the muscle of ALS mouse model demonstrating that the expression of AChRs was impacted and muscle mass loss was decreased. This may represent an interesting strategy to avoid muscle atrophy and counteract muscle and motor neuronal alterations occurred in ALS patients.

1227 Development of Therapeutic Extracellular Vesicle Enveloped-AAV Vectors for Muscle Gene Therapy

Joshua J. Kauffman[1], Nizar Y. Saad[2]

[1]Center for Gene Therapy, Nationwide Children's Hospital, Columbus, OH,[2]Center for Gene Therapy, The Ohio State University and Nationwide Children's Hospital, Columbus, OH

Introduction: Translating gene therapy for muscular disorders is challenging because systemic delivery of high Adeno-Associated Virus (AAV) doses is required, increasing the risks of treatment-related immune responses and adverse events. To overcome these limitations, we developed muscle-targeting extracellular vesicle enveloped-AAV vectors (myoEV-AAV), aiming to increase transduction potency to skeletal muscle and shield AAV from neutralizing antibodies (NAbs). **Methods:** We purified AAV using iodixanol (IDX) density gradient and anion exchange HPLC. We purified EV-AAV using IDX density gradient or size-exclusion chromatography (SEC). We characterized EV size, frequency, purity, and surface markers profile using NTA and western blots. We used Transmission Electron Microscopy (TEM) to determine EV-AAV structure and validate AAV packaging. We used a reporter system to determine EV-AAV transduction efficiency into HEK293 cells, myoblasts and muscle. We performed a neutralizing antibody assay (NAA) to determine EV-AAV resistance to NAbs. **Results:** Our data showed better EV-AAV purification using SEC with which we obtained one Log higher EV yield and a 5-fold higher AAV yield. SEC had better resolution in separating eluates. Using TEM, EV-AAVs had an inflated rather than a collapsed structure. EV-AAV was ~2-fold more efficient than AAV in transducing HEK293s but had similar efficiency in transducing myoblasts when we used EVs packaging myotropic AAVs (MYOAAV). Intramuscular injection of EV-MYOAAV into the tibialis anterior of C57BL/6 mice showed higher transduction efficacy than that of MYOAAVs. Using NAA, EV-AAV showed resistance to serum AAV-NAbs. Finally, we successfully targeted EV-AAVs to myoblasts using muscle-specific peptides. **Conclusion:** We have proof-of-concept for designing and producing muscle-specific EV-AAVs that transduce with high efficiency skeletal muscles and shield AAV from NAbs. Next, we will validate our results using systemic delivery of EV-AAVs.

1228 Gene Therapy for Treating Sialidosis

Wuh-Liang Hwu[1], Karine Chang[1], Yu-Han Liu[2], Hao-Chun Wang[1], Ni-Chung Lee[3], Yin-Hsiu Chien[3]

[1]Department of Pediatrics, Nation Taiwan University Hospital, Taipei, Taiwan,[2]Department of Medical Genetics, Nation Taiwan University Hospital, Taipei, Taiwan,[3]Department of Medical Genetics, National Taiwan University Hospital, Taipei, Taiwan

Patients with sialidosis (mucolipidosis type I) typically present myoclonus, seizure, ataxia, cherry-red spot, and blindness, because of mutations in the neuraminidase I (*NEU1*) gene. Currently, there is no treatment for sialidosis. In this study, we developed an adeno-associated virus (AAV)-mediated gene therapy for a *Neu1* knockout mouse model (*Neu1*$^{-/-}$). The vector included human *NEU1* promoter, *NEU1* cDNA, IRES, and human protective protein/cathepsin A (PPCA) cDNA. Untreated *Neu1*$^{-/-}$ mice showed astrogliosis and microglia activation in the brain and lysosomal storage in dorsal rout ganglion (DRG)

neurons, together with impaired motor function. Co-expression of NEU1 and PPCA in neurons and microglia by intracerebroventricular or facial vein injection of neonatal *Neu1*$^{-/-}$ mice resulted in decreased astrocyte proliferation and microglia activation. Rotarod performance and grasping power were both improved. In facial vein-injected *Neu1*$^{-/-}$ mice, lysosomal storage in DRG neurons was decreased and body weight was improved. There was no vector-related adverse event. Therefore, AAV-mediated gene therapy is safe and efficient for treating *Neu1*$^{-/-}$ mice.

1229 Neuronal Transduction of AAV-Progranulin Corrects Microglial Lipofuscinosis and Pro-Inflammatory Microglial Morphology in a Mouse Model of Progranulin Deficiency

Shreya N. Kashyap, Katherine I. WIlson, Andrew E. Arrant, Erik D. Roberson

Neurology, University of Alabama Birmingham, Birmingham, AL

State of the Art: Of the more than 70 *GRN* mutations associated with FTD, nearly all cause progranulin haploinsufficiency. Therefore, progranulin replacement is a straightforward therapeutic approach for the FTD-*GRN* patient population. There are two AAV-Progranulin gene therapeutics currently in clinical trials. PR006, manufactured by Prevail Therapeutics, is a human progranulin transgene product packaged in an AAV9 capsid which transduces both neurons and astroglia. PBFT02, manufactured by Passage Bio, is human progranulin packaged in an AAV1 capsid, which selectively transduces neurons. Our lab has developed a novel mouse progranulin construct packaged in AAV1, which despite selectively transducing neurons, also has the ability to correct microglial lysosomal dysfunction in progranulin homozygous knockout (*Grn*$^{-/-}$) mice as measured by CD68 immunostaining, and to decrease microglial soma size, as measured by IBA1-positive particle analysis of DAB micrographs. Here, we further characterized microglial phenotypes of *Grn*$^{-/-}$mice, using a combination of high resolution microscopy and computational techniques and confirmed that our novel neuron-targeting AAV-Progranulin construct has the ability to correct **both** neuronal and microglial phenotypes of progranulin deficiency.**Methodology:** A blinded experimenter used 3D Slicer to manually segment and perform 3D reconstruction of microglia from 40X Z-stacks of IBA1-stained sections of *Grn*$^{-/-}$and *Grn*$^{+/+}$ brains. We also used a MATLAB-based script which segments and skeletonizes microglia based on a threshold set by the user. We repeated these analyses with *Grn*$^{-/-}$ mice that received AAV1m*Grn* or AAV1GFP. We concomitantly measured neuronal lipofuscinosis and evaluated levels of microglial disease-associated markers in both AAV1mGrn and AAV1GFP treated mice. Finally we used confocal microscopy of IBA1-stained sections, and measured autofluorescent lipofuscin deposits within microglial ROIs, via a ImageJ/FIJI pipeline. We also developed a PYTHON-based script to quantitate the volume of lipofuscin within each microglial cell, and performed analyses to correlate microglial lipofuscin with hyperinflammatory morphology. **Results:** *Grn*$^{-/-}$ mice had age-dependent increases in microglial lipofuscinosis and microglial cell volume, territorial volume, and average branch length, and AAV1m*Grn* treatment corrected these morphologic and lysosomal phenotypes. AAV1mGrn treatment also corrected neuronal lipofuscinosis. Exogenous progranulin was detected only in neurons, not microglia. **Conclusions:** Neuronal transduction of our novel AAV-Progranulin improves the cross-correctional capacity of progranulin, allowing it to reduce both neuronal lipofuscinosis, as well as microglial lipofuscinosis and pro-inflammatory microglial morphology in *Grn*$^{-/-}$ mice.

1230 Novel Method of Producing AAV Capsid Libraries in Insect Cells

Bas Bosma[1], Elena Santidrian Yebra-Pimentel[1], Tom van der Zon[1], Lyubomir Momchev[1], Milja Pesic[2], Noun Bashir[2], Marsha Haneveld[2], Angga Kusuma[1]

[1]Vector Technologies, uniQure NV, Amsterdam, Netherlands,[2]Process Development, uniQure NV, Amsterdam, Netherlands

Adeno-associated virus (AAV) capsid development via directed evolution is a powerful approach that allows relatively fast selection of virus variants with novel properties. To date, the main production platform for AAV capsid libraries used by this approach has been the HEK platform, in which capsid DNA libraries are delivered into the mammalian cells via transfection. While this method allows for the production of libraries of sufficient depth and titer, it requires the transfection of high quantities of DNA per cell, making the method prone to cross-packaging. Here, we propose a novel method for generating AAV capsid libraries in insect cells that significantly reduces the amount of DNA transfected per cell, while maintaining high AAV titers and library depth. Importantly, the capsid lead candidates selected from these libraries would be directly compatible with both mammalian and insect cell-based AAV production platforms. Our DNA libraries were built upon our proprietary plasmids, which are amplified and prepared with a three-step process to produce the AAV capsid libraries. Analysis of process intermediates revealed that even though a low amount of DNA libraries was transfected per insect cell, high AAV titers were produced, and that the efficiency of AAV recovery through the downstream process was ~40%. Furthermore, using next generation sequencing analysis we found that our method maintains the library complexity throughout the whole process, with the largest reduction in complexity occurring at the AAV production step. The level of cross-packaging of the method was measured using the limiting dilution assay followed by NGS analysis, and was found to be low compared to the cross-packaging reported for HEK-produced capsid libraries. Taken together, our data suggest that the newly proposed workflow generates AAV libraries of superior quality, suitable for AAV capsid development via directed evolution.

1231 A Novel Approach to Mass Spec Sample Preparation of AAV Capsid Protein for Peptide Mapping and Host Cell Protein Impurity Analysis

Kara B. Machleidt, Trish Hoang, Sergei Saveliev, Marjeta Urh, Michael M. Rosenblatt

Promega Corporation, Madison, WI

Introduction The characterization of biotherapeutic proteins, prior to approval for use in Humans, has been the subject of immense research. Initial efforts focused hormones (Insulin), followed by the mainstream use of therapeutic antibodies. Recently, Adeno- Associated Virus (AAV) has emerged as a prominent delivery vector for Gene Therapy.

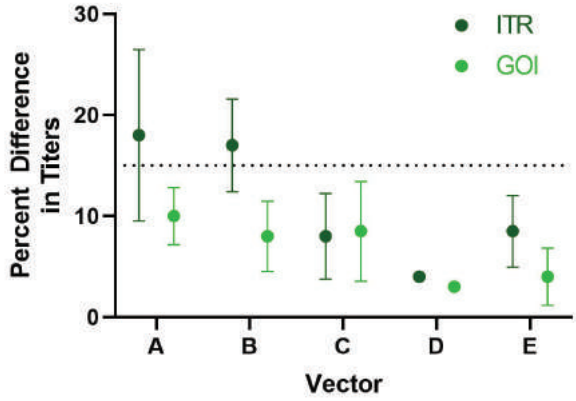
Characterization of capsid proteins and host cell protein (HCP) contaminants, has proven to pose several challenges particularly due to the stability of the viral particle and the abundance of HCPs. We have developed novel protocols for capsid peptide mapping and HCP analysis, involving precipitation of capsid proteins onto the surface of magnetic beads, followed by proteolysis with multiple proteases to maximize sequence coverage and identification of HCPs. **Results** An initial screen of Capsid solubilization revealed that heating and reducing agents were required for disruption of capsid particles, as revealed by SDS-PAGE analysis and quantitative protein assay. Surfactants improved the solubilization process, although native conditions, also gave favorable results. The use of hydrophilic magnetic beads, both as a tool for removing mass spec incompatible solutes as well as a mechanism for protein denaturation, was employed for capsid proteolysis. Our findings reveal that proteolysis with trypsin, is able to give 75 % sequence coverage of the entire VP1 Capsid protein (the longest isoform). Analysis of the Capsid sequence revealed the presence of 2 large patches of amino acid sequence (170 - 239 and 322 - 389) on the protein that predict tryptic peptides to be larger than 4000 Daltons, which is above the practical limit for peptide mapping. In an effort to increase the coverage of the protein, alternative proteases, known to be orthogonal to trypsin were utilized to improve subsequent sequence coverage. In addition, using our novel sample preparation approach, 128 human protein impurities derived from the HEK host cell were identified, with high confidence. The abundance of these host-cell impurities, relative to their natural abundance within the HEK cellular proteome will be compared. The use of additional proteases, to increase the number and confidence of protein impurities will be discussed. In addition, a DOE based approach to protocol optimization and the use of sequential digestion with orthogonal proteases will be presented. **Conclusion** We have developed an optimized, robust, and universal sample preparation method for the Peptide Mapping and Host Cell Protein Impurity analysis of AAV Capsid particles. We demonstrated that this method allows for maximum sequence coverage and identification of HCPs with high confidence.

1232 Optimizing Viral Genome Titer Methods: A Case Study on Improving Titer Accuracy Using ITR

Rosalie Bateson, Alexander Turner, Vickie Dowling, Wayne Yount

Kriya Therapeutics, Research Triangle Park, NC

The viral genome titer method by PCR is an industry standard method to quantify AAV in order to deliver accurate doses of gene therapy products. While sequences unique to the gene of interest (GOI) are the preferred PCR target for titer determination, other targets, such as the Inverted Terminal Repeats (ITR), are desirable for early stages of development because they allow for comparability across multiple constructs with variances in GOI nucleotide sequence. The ITR can be a difficult target to work with due to its complex native structure. However, the ITR is often the only universal target when comparing constructs when down selecting lead candidates. Here we present a case study where two sample preparation methods resulted in significantly different ITR titers. This method-dependent difference was specific to vector design and only observed in two vectors out of five analyzed (Figure 1). For all vectors tested, the determined GOI titers were not significantly different between the two methods (Figure 1).



The two vectors impacted used a modified titer calculation due to differing fragmentation in the method. Fragmentation of vector DNA occurs with use of restriction enzymes that cut within the secondary structure of the ITR, such as MspI. For vectors C, D, and E, MspI cut sites are present throughout the vector genome, resulting in the ITRs being split into two different fragments. Vectors A and B have no MspI cut sites between the ITRs theoretically resulting in two ITR targets per packaged vector genome. Accurate titer quantification of Vectors A and B assumes that all vector genomes remained intact throughout the ddPCR sample analysis procedure. Fragmentation during the sample preparation was evaluated using a capillary electrophoresis (CE)-based vector genome integrity method which separates single-stranded DNA based on size. The CE data showed that heterogenous fragmentation of the vector genome occurred during the sample preparation. Less fragmentation occurred in the streamlined workflow with reduced exposure to high temperatures (>70°C). This difference in fragmentation likely accounted for the difference in ITR titers between the two methods for Vector A and B because of the unique assumption that all fragments contain both ITRs after the MspI digest. We were able to confirm this hypothesis with use of an additional restriction enzyme which splits the ITRs into multiple different fragments (Table 1). Based on these results, the additional restriction enzyme will be added to the sample preparation workflow.

Table 1. ITR differences between two sample preparation methods

	Minus Restriction Enzyme	Plus Restriction Enzyme
Method 1 Viral Genome Titer by ITR (vg/mL)	3.5E+13	2.0E+13
Method 2 Viral Genome Titer by ITR (vg/mL)	2.8E+13	1.9E+13
% Difference Method 1 vs Method 2	24%	6%

Using ITR as a PCR target allows for the use of a consistent titer method throughout the lifecycle of our programs. While the ITR may be a challenging target for PCR-based titer methods, we have demonstrated that accurate results can be achieved through sample preparation optimization. A comparison of two sample preparation workflows revealed conditions that negatively impacted the accuracy of ITR titers for a specific set of vectors. The use of an orthogonal CE method for vector genome integrity allowed the cause of the inaccuracies to be determined and an effective solution was implemented.

1233 Liver-Specific Knock-In Using Low-Dose AAV-CRISPR Restored Hemostasis in Neonatal Hemophilia B Mice with Low Antibody Response

Zhang Zhenjie

The Chinese University of Hong Kong, Hong Kong, Hong Kong

AAV-delivered CRISPR/Cas9 (AAV-CRISPR) has shown promising potentials in preclinical models to efficiently insert therapeutic gene sequences in somatic tissues. However, the AAV input doses required were prohibitively high and posed serious risk of toxicity. Here, we performed AAV-CRISPR mediated homology-independent knock-in at a new target site in *mAlb* 3'UTR and demonstrated that single dose of AAVs enabled long-term integration and expression of *hF9* transgene in both adult and neonatal hemophilia B mice (*mF9 -/-),* as evidenced by high levels of circulating hFIX and hemostasis restoration during entire 48-week observation period. Furthermore, we achieved hemostasis correction with a significantly lower AAV dose (2×10^9 vg/neonate and 1×10^{10} vg/adult mouse) through liver-specific gene knock-in using hyperactive $hF9^{R338L}$ variant. The plasma antibodies against Cas9 and AAV in the neonatal mice receiving low-dose AAV-CRISPR were negligible, which lent support to the development of AAV-CRISPR mediated somatic knock-in for treating inherited diseases.

1235 Clearance of Intracellular Free Cholesterol by Liver-Targeted LNP-mRNA Therapy Reverses NASH Pathology

Garrett Strough, Iyan Warren, Karim Sahbani, Stephen Plencner, Ian Laih, Reason ., Guilherme Cherman Perdigão de Oliveira, Mourad Topors

Repair Biotechnologies, Inc., Syracuse, NY

Cholesterol content is elevated in the livers of humans with non-alcoholic steatohepatitis (NASH) and raised levels of unesterified "free" cholesterol correlate with disease severity. High-cholesterol diets promote NASH in mouse models of diet-induced obesity. Hepatic steatosis coupled with sustained, maladaptive inflammation leads to progressive liver cell injury and fibrosis. To potentially treat this condition with high unmet need, we developed the Cholesterol Degrading Platform (CDP), an engineered fusion protein that confers on cells the ability to safely degrade excess free cholesterol into a non-toxic catabolite that is eliminated by the kidneys. Our reduction of NASH pathology with a liver-targeted lipid nanoparticle (LNP)-encapsulated CDP mRNA therapy indicates a novel approach to treating and reversing NASH. **Methods:** Male C57B6/J mice were fed a high-fat/high-cholesterol diet for 52 weeks to develop NASH. Mice were placed on normal chow, divided into two groups and treated with either (A) LNP-CDP mRNA (1mg/kg iv, qw ; n=15/group) or (B) LNP-Empty (1mg/kg iv, qw ; n=15/group) for 8 weeks. At study end, mice were sacrificed and blood and tissues were harvested and processed for analysis. **Results:** Body weights and serum AST/ALT ratios remained unchanged in LNP-CDP mRNA treated mice versus controls.

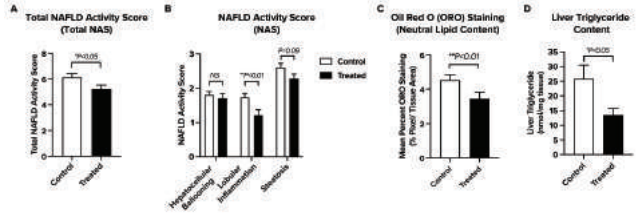


Figure 1. LNP-CDP mRNA Reduces NAFLD Activity Score in a model of NASH. A) Treatment significantly reduced total NAFLD Activity Score (NAS, *P<0.05 vs Control) which represents the sum of the scores of hepatocellular ballooning, lobular inflammation, and steatosis. B) The treatment had its greatest effects on lobular inflammation (**P<0.01 vs Control) and steatosis (P=0.09), while hepatocellular ballooning remained unchanged. While this scoring of liver steatosis did not reach our desired level of statistical confidence, treatment significantly reduced other measures of liver lipid content including C) liver Oil Red O staining(**P<0.01 vs Control) as well as D) liver triglyceride content (*P<0.05 vs Control).

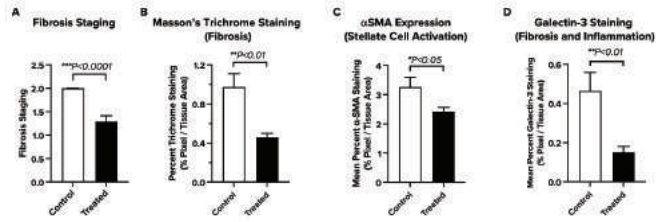

Figure 2. LNP-CDP mRNA Reduces Fibrosis and Markers of Hepatic Stellate Activation. Compared to control, treatment led to A) a significant reduction in overall fibrosis stage based on assessments of liver H&E sections (**P<0.0001 vs Control), also supported by B) a 52% decrease in Masson's Trichrome fibrosis staining (**P<0.01 vs Control). C) Treatment with REP-0002 led to a 26% reduction in α-SMA staining (P<0.05), suggesting attenuation of hepatic stellate cell activation, a major inciting mechanism and driver of liver fibrosis in NASH. Additionally, D) we observed a 67% reduction in galectin-3 staining, an established surrogate marker of tissue inflammation, fibrosis, and overall NASH severity. **Conclusion:** Our data provides strong preliminary evidence that the removal of excess free cholesterol from the liver using LNP-CDP mRNA therapy is safe and very well-tolerated, suggesting a first-in-class approach to attenuate and reverse NASH pathology.

1236 A Powerful Immunoassay Platform for Protein Expression Potency Testing

Rachel Talis, Francisco Ramirez, Charles Haitjema, John Eugenis, Chris Heger

Bio-Techne, San Jose, CA

Gene therapies offer new treatments and cures for deadly diseases, but a major challenge is the lack of fit-for-purpose analytical technologies

for monitoring critical quality attributes (CQAs). Potency is an essential CQA that has been overlooked by manufacturers and is often a sticking point with regulatory agencies. Existing analytical solutions are outdated and do not meet modern manufacturing needs. Simple Western, a capillary electrophoresis platform that incorporates a quantitative immunoassay, is a next-generation fit-for-purpose tool for gene therapy analytical testing. It excels at working in complex cell lysates or tissue homogenates, offers high sensitivity, and can monitor multiple CQAs, including potency. Here we detail a relative potency assay for a AAV gene therapy on Simple Western and characterize the analytical performance of the assay. Simple Western uses a single antibody and provides quantitative immunoassays in complex samples, making it a valuable tool in manufacturing workflows.

1237 Assessing Tissue-Specific Gene Therapies in a Pre-Clinical Mouse Model of Lipodystrophy

Mansi Tiwari[1], Nadine Sommer[1], Ahlima Roumane[1], Weiping Han[2], Mirela Delibegovic[3], Justin J. Rochford[1], George D. Mcilroy[1]

[1]The Rowett Institute, University of Aberdeen, Aberdeen, United Kingdom,[2]Institute of Molecular and Cell Biology, Agency for Science, Technology and Research (A*STAR), Singapore, Singapore,[3]Institute of Medical Sciences, University of Aberdeen, Aberdeen, United Kingdom

Congenital generalised lipodystrophy (CGL) is a rare and life-threatening disorder. Patients with CGL fail to develop appropriate adipose tissue stores. This leads to the development of severe metabolic complications, including hepatic steatosis, lipoatrophic diabetes and cardiovascular disease. There is currently no cure for CGL, and treatment options remain limited. Adipose tissue has emerged as a target for adeno-associated virus (AAV) vectors. We recently revealed that systemic AAV-mediated gene therapy restores adipose tissue development and metabolic health in a pre-clinical mouse model of CGL. Here, we utilised the human cytomegalovirus (CMV) promoter to drive constitutive transgene expression. We have subsequently investigated whether tissue-specific AAV vectors can provide a more targeted form of therapeutic intervention for CGL. We combined AAV8 vectors with the mini/aP2 or thyroxine-binding globulin promoter to specifically target adipose tissue and liver, respectively. Additionally, AAV-mini/aP2 vectors contained the liver-specific microRNA-122 target sequence to limit hepatic expression of our transgene. Our data indicate that systemic delivery of adipose or liver specific AAV vectors restores adipose tissue development and improves metabolic health in mice with CGL. Hyperglycaemia was normalised two weeks post-treatment ($p<0.001$, n=5/AAV vector) compared to AAV-CMV-eGFP treated controls. Glucose and insulin tolerance was significantly improved, and liver weights were significantly reduced in both treatments ($p<0.0001$, n=5/AAV vector). Surprisingly, hepatic steatosis was only improved with AAV-mini/aP2 vector administration ($p<0.0001$, n=5), indicating divergent effects dependent on promoter selection. We propose that tissue-specific AAV-mediated gene therapy may offer an effective form of therapeutic intervention to correct metabolic dysfunction in patients with CGL.

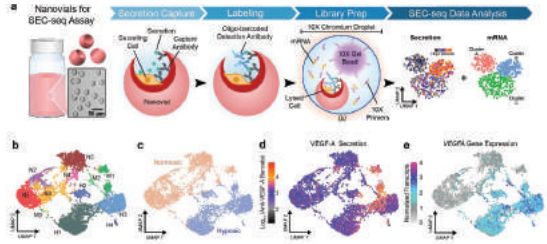
1238 Unveiling the Molecular Landscape of Highly Secretory MSCs through Secretion Encoded Single-Cell Sequencing (SEC-seq)

Shreya Udani[1], Justin Langerman[2], Doyeon Koo[3], Sevana Baghdasarian[4], Brian Cheng[1], Simran Kang[1], Citradewi Soemardy[1], Joseph de Rutte[5], Kathrin Plath[2], Dino Di Carlo[1]

[1]Bioengineering, University of California, Los Angeles, Los Angeles, CA,[2]Biological Chemistry, David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA,[3]Bioengineering, University of California Los Angeles, Los Angeles, CA,[4]Chemical Engineering, University of California, Los Angeles, Los Angeles, CA,[5]Partillion Bioscience, Los Angeles, CA

Cell function is defined by a myriad of biomolecules that they secrete. Mesenchymal stromal cells (MSCs) have been widely evaluated as therapeutics because they secrete growth and neurotrophic factors, cytokines, and extracellular vesicles, which promote immunomodulation and regeneration. However, there is a lack of methods to probe the heterogeneity in secretory functions and link these to specific gene expression networks at scale. Methods to sort therapeutic cell populations by functional potency and uncover the single-cell level gene expression driving this potency can transform the next generation of cell therapies. We introduce a new multiomics method to profile the secretion phenotype of tens of thousands of single cells and link this with the associated transcriptome using scRNA-seq. Secretion encoded single-cell sequencing (SEC-seq) leverages nanovials (hydrogel particles with nano-liter sized-cavities) and standard flow cytometry and scRNA-seq platforms to retain and analyze both transcriptome and secretion information from the same cells. Cells are loaded into gelatin-coated nanovials conjugated with capture antibodies for a secreted protein of interest, allowing the cells to adhere to the nanovial surface and secreted protein to bind to the capture antibodies. After incubation, nanovials are labeled with oligo-barcoded detection antibodies against the secreted product. Single-cell loaded nanovial samples, enriched by FACS, are then partitioned for downstream scRNA-seq, including library preparation for mRNA and oligo-barcode detection, sequencing, and data analysis (Figure 1a). We show the utility of SEC-seq by uncovering the relationship between the secretion of vascular endothelial growth factor A (VEGF-A) and the underlying transcriptome state in MSCs under normoxic and hypoxic conditions for the first time. Surprisingly, we found a relatively low correlation between VEGF-A secretion and *VEGFA* transcript levels across cells in both conditions. Yet, a subset of cells (5-20%) found in normoxic and hypoxic conditions secrete high levels of VEGF-A (Figure 1b-d; cluster M1). This subpopulation is not defined by increased *VEGFA* transcript levels; instead, it is characterized by a unique, secretory gene-enriched transcription profile. We coined this gene signature the "Vascular Regenerative Signal" due to the presence of transcripts related to cell motility, blood vessel development, and wound response, and its link to the high VEGF-A secretory state. The induction of the hypoxic response globally elevates *VEGFA* transcript levels and VEGF-A secretion across all cells, indicating that the modulation of *VEGFA* transcript levels can tune the secretion output under certain conditions. Overall, our findings demonstrate the need to probe secretion and transcriptome simultaneously to better understand

the regulation of protein secretion, and SEC-seq introduces a new method that leverages standard cytometry tools and can be broadly adopted to explore these linkages across any cells.



1239 Enhanced AaCas12b^{Max}-Mediated Disruption of a *cis*-Element in *HBG* Promoter to Generate HPFH Mutations in HSPCs for the Treatment of β-Thalassemia

Yue Meng Zhao, Yule Shao, Wenli Min, Xiaoping Zhao, Shin-Shay Tian, Su Qu

Shanghai Vitalgen BioPharma Co. Ltd, Shanghai, China

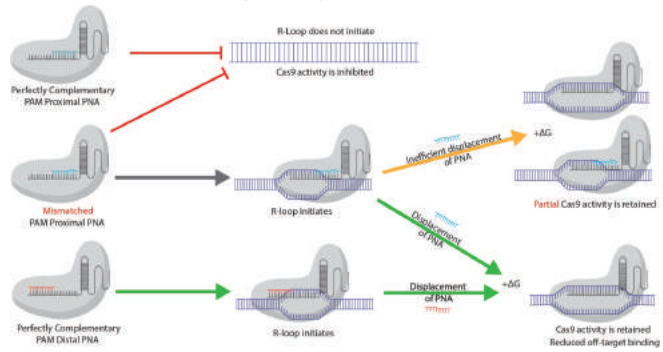
β-thalassemia is an inherited blood disorder that is caused by a collection of *HBB* gene mutations resulting in insufficient β-hemoglobin production. Recent advances in nuclease-based approaches for genome editing, particularly applying CRISPR/Cas, have efficiently generated hereditary persistence fetal hemoglobin (HPFH)-like mutations in hematopoietic stem and progenitor cells (HSPCs) to reactivate HbF expression in erythroid lineages as an effective and endurable gene therapy for β-thalassemia. It has been demonstrated that HPFH-like mutations at the −200 bp and −115 bp upstream of the *HBG1/2* transcription start sites (TSSs) will inhibit the binding of HBG repressors and thus awaken γ-globin expression from developmental silencing. Here, we evaluated the effectiveness of a proprietary type V-B CRISPR nuclease (AaCas12b^{Max}) in combination with a single guide RNA (sgRNA) to generate genetically modified HSPCs for the treatment of β-thalassemia. Using an optimized AaCas12b^{Max}:sgRNA ribonucleoprotein (RNP) complex, we achieved editing efficiencies of >90% at the LRF binding site upstream of *HBG1/2* in both HSPCs from healthy donors and β-thalassemia patients. Indel profiles from deep sequencing showed that the optimized AaCas12b^{Max}-RNP mediated cleavage led to larger indels than spCas9 did and the most frequent mutations were >10 bp deletions by microhomology-mediated end joining (MMEJ) repairs. The AaCas12b^{Max}-RNP evaluated was highly specific for the HBG locus editing in HSPCs, with no detectable off-target activity (below 0.1% allele frequency) identified at any projected potential off-target sites as evaluated by *in silico* modeling, Tag-seq cellular assay and SITE-seq biochemical assay. To evaluate HBF reactivation after the HBG locus editing, the edited HSPCs were induced to differentiate into the erythroid lineage *in vitro*. Significant HbF induction in the edited erythroid progeny was detected by flow cytometry analysis of the F-cell (CD235a+/HbF+) percentages and HPLC analysis of the HbF protein expression. The edited HSPCs maintained their engraftment and lineage differentiation potential as evaluated together with unedited HSPCs in immunodeficient mice. The engraftment of the edited HSPC-derived erythroid cells resulted in the increase of the HbF protein levels and corrected the globin protein expression balance in the study subjects. In summary, we have demonstrated that our proprietary AaCas12bMax-RNP-mediated disruption of a *HBG cis*-element in HSPCs is a promising therapy for the treatment of β-thalassemia.

1240 Modulating Cas9 Activity and Specificity Using Antispacer PNAs for Allele Specific Gene Editing

Kelly E. W. Carufe[1], Nicholas G. Economos[1], Peter M. Glazer[2]

[1]Yale University, New Haven, CT,[2]Yale University School of Medicine, New Haven, CT

While CRISPR-Cas9 gene therapies have proven to be a powerful tool for gene editing, one area where there could be improvement is in allele-specific targeting to treat various autosomal dominant diseases in situations where preservation of the wild-type allele is required. Single base pair mismatches between wildtype and mutant sequences can prove challenging for Cas9 to differentiate depending on location relative to the PAM site. Here we use synthetic peptide nucleic acids (PNAs) that bind selected spacer sequences in the guide RNA (gRNA) to increase the specificity of Cas9. We demonstrate that PNAs which bind over the PAM distal region of the gRNA allow retention of on-target editing while reducing off-target effects. We also show that PNAs that are perfectly complementary to the PAM proximal region completely shut down Cas9 activity while PNAs with key mismatches in the same region have different abilities to modulate Cas9 editing depending on where the mismatch falls in the gRNA sequence. These effects range between complete inhibition of Cas9, moderate inhibition, or no inhibition of Cas9. We hypothesize that these distal and proximal PNA designs will allow allele specific discrimination by increasing the specificity of Cas9 cutting activity.



1241 Vector Biodistribution and Transgene Expression in the Heart Following Gene Transfer of AAVrh.10 vs. AAV9 Capsids

Nithya Selvan[1], Anju Nair[1], Anthony S. Fargnoli[1], Jing Zhang[2], Jie Wang[2], William H. Bradford[2], Sonia Gutierrez Granados[1], Kenneth M. Law[1], Tim Fenn[1], Paul McCormac[1], Jay Barth[1], Farah Sheikh[2], Richie Khanna[1]

[1]Lexeo Therapeutics, New York, NY,[2]University of California, San Diego, La Jolla, CA

AAV9 is a widely used gene transfer vector to target the heart; however, its biodistribution and functional effects relative to other cardiotropic AAV vectors, such as AAVrh.10 have not been fully elucidated. Here we investigated the differential biodistribution of AAVrh.10 versus AAV9 encoding a reporter transgene in a wildtype porcine model, as well as the functional effects of delivering a therapeutic transgene using these capsids in a mouse model of heart disease. By exploiting quantitative whole-body imaging of I-124 labelled AAV vectors, it was previously shown that AAVrh.10 distribution was ~2-fold higher in the heart when compared to AAV9 within the first 72 hours post intravenous administration in African green monkeys (Ballon et al, 2020, Hum Gene Ther 31:1237-1259). Vectors were administered intravenously to pigs, and hearts harvested for analysis two weeks post treatment. Consistent with findings in NHPs, we show using qPCR analysis of hearts from minipigs treated with AAVrh.10eGFP and AAV9eGFP, that the overall biodistribution of AAVrh.10eGFP in various cardiac regions was ~1.5-fold greater than AAV9eGFP (n=4 per vector group and n=2 for vehicle group). In addition, eGFP transgene expression analysis of porcine hearts using quantitative Westerns and immunohistochemistry also showed a similar ~1.5-fold greater expression with AAVrh.10 capsid compared to AAV9. To assess the functional impact of improved vector biodistribution and transgene expression we tested the efficacy of AAVrh.10 vs. AAV9 encoding human plakophilin-2 (PKP2) transgene in a severe mouse model of arrhythmogenic right ventricular cardiomyopathy (ARVC) harboring a mutation in the *PKP2* gene. AAVrh.10hPKP2 or AAV9hPKP2 was administered intraperitoneally at postnatal day 2 to PKP2 Hom mice (n=6 for vehicle group, n=5 per treatment group). Mice were evaluated for cardiac function using magnetic resonance imaging (MRI) 4-weeks post vector administration. MRI analysis showed improved (~2 fold) left and right ejection fraction in mice treated with AAVrh.10hPKP2 compared to mice treated with AAV9hPKP2. AAVrh.10 also showed reduced right and left end-diastolic and systolic volumes when compared to AAV9. Collectively, these data generated using different animal models demonstrate that all parameters studied (vector biodistribution, transgene expression, and cardiac functional rescue) trend better with AAVrh.10 capsid compared to AAV9.

1242 Dissecting the Mechanisms of CAR-T Cell Dysfunction in a Mouse Model of Solid Tumors

Paula Barbao[1], Berta Marzal[1], Irene Andreu-Saumell[1], Alba Rodriguez-Garcia[1], Joan Castellsagué[1], Marta Giménez-Alejandre[1], Anna Esteve-Codina[2], Marta Soria-Castellano[1], Aleix Prat[3], Alvaro Urbano-Ispizua[4], Sonia Guedan[1]

[1]Fundació Clínic per la Recerca Biomèdica, Barcelona, Spain,[2]Centre de Regulació Genòmica CNAG-CRG, Barcelona, Spain,[3]Medical Oncology Department, Hospital Clínic de Barcelona, Barcelona, Spain,[4]Hospital Clínc de Barcelona, Barcelona, Spain

CAR-T cell immunotherapy has demonstrated remarkable efficacy against hematologic malignancies, but their efficacy against solid tumors remains limited. Successful tumor eradication by CAR-T cells relies on maintaining highly effective antitumor T cells despite persistent antigen stimulation and immunosuppressive networks in the tumor microenvironment. CAR-T cell dysfunction has been recently explored by other groups using in vitro models of chronic antigen stimulation or CARs that induce tonic signalling. Here, we have generated a xenograft mouse model of HER2+ solid tumors in which infused anti-HER2 CD28-based CAR-T cells are driven to a dysfunctional state. We have isolated tumor infiltrating T cells at two different phases: 1) an initial phase of T cell activation that leads to tumor regression (named "effective CAR-TILs") and 2) a second phase of progressive loss of T-cell function and tumor escape (named "dysfunctional CAR-TILs"). Phenotype, function and transcriptional signatures of effective and dysfunctional TILs have been analysed. Immunohistochemistry analysis of tumors treated with anti-HER2-CAR-T cells showed CD8+ infiltration and persistence of the targeted antigen after escape to treatment. Dysfunctional TILs expressed high levels of PD-1 and had lost the expression of the proliferation marker Ki67. When using a real-time cytotoxicity assay, effective but not dysfunctional CAR-T cells were able to lyse tumor cells. We observed impaired production of cytokines and cytotoxic molecules such as IFNg, granzymes A and B and FasL in dysfunctional TILs when co-cultured with tumor cells ex vivo. However, TILs at the dysfunctional phase released higher IL-6 than effective TILs. Contrary to previous reports, the loss of effector functions observed in dysfunctional CAR-TILs was not reversible after overnight resting. This dysfunctional phenotype was not specific to CAR signalling since stimulation with PMA/Ionomycin did not rescue T cell function. Principal component analysis of RNA-sequencing data revealed strong differences between effective and dysfunctional CAR-TILs with 2.472 differentially expressed genes. Using Ingenuity Pathway Analysis, we found T cell exhaustion and senescence pathways enriched in dysfunctional CAR-TILs. We also observed NK cell-like signatures in our model as hallmark of exhaustion as recently published. Surprisingly, while effective TILs retained their effector functions and were able to induce tumor regression in mice, T cell exhaustion gene signatures were also early enriched in effective TILs. To further study the dynamics and mechanisms mediating loss of CAR-T cell function in our model we performed a soft clustering analysis of gene expression profiles from effective and dysfunctional CAR-TILs and the preinfusion product. We identified cell adhesion genes to be progressively upregulated in the dysfunctional phase, whereas genes related to metabolic and biosynthetic processes were downregulated. Using high throughput

screening we aim at providing a better understanding of the function of candidate genes in T cell effector functions and/or T cell dysfunction. Altogether our results suggest that CAR-T cell dysfunction state begins early after treatment in the tumor microenvironment and ultimately leads to treatment failure. Understanding the underlying mechanisms leading to loss of T cell functions is key to unleash the full potential of CAR-T cell therapy in solid tumors.

1243 Novel AAV9 Peptide Insertion Variants with Improved Tropism Tailored for Effective Retinal Gene Therapy

Sabrina Babutzka[1], Jacqueline Bogedein[1], Hildegard Buening[2], Stylianos Michalakis[1]

[1]Department of Ophthalmology, University Hospital, LMU Munich, Munich, Germany,[2]Laboratory for Infection Biology and Gene Transfer, Institute of Experimental Haematology, Hannover Medical School, Hannover, Germany

Gene therapy has gained importance in recent years as a treatment option for inherited retinal dystrophies. In different preclinical studies, gene supplementation (or augmentation) therapy using recombinant adeno-associated viral (AAV) vectors has proven effective in halting the progression of retinal degeneration and preventing blindness. Despite many advantages, AAV vectors still have some limitations, such as the need for local delivery via subretinal injection, which carries the risk of collateral retinal damage, or limited efficiency in reaching and transducing cells outside the subretinal injection area. Here we introduce two novel engineered AAV9 variants optimized for effective photoreceptor-targeting after a less invasive intravitreal administration. These variants carry small peptide insertions in the surface exposed variable loop IV of the AAV9 capsid. AAV9 has so far not been widely used for retinal use but has certain advantages over other serotypes, such as a lower prevalence of pre-existing immunity in the human population and good neuronal tropism. Previously, heparan-sulfate proteoglycan (HSPG) binding has been shown to contribute to the retinal cell tropism of AAV vectors. Therefore, we introduced an artificial HSPG binding site with the peptide insertions to investigate how this affects penetration into the retinal cell layers after intravitreal administration. A total of ten different AAV9-based variants were assessed regarding thermal capsid stability, *in vitro* transduction properties and *in vivo* tropism in mouse retina. To this end, the novel AAV variants were packaged with a CMV-eGFP fluorescence reporter cassette and tested on several different tissue types. Transduction efficiencies were initially tested *in vitro* in HeLa cells at three different MOIs. AAV9.NNR and AAV9.GLR outperformed AAV9 wild type as well as previous AAV9 variants lacking a HSPG motif. Selected variants were also tested in *ex vivo* human retinal tissue explants with the AAV9.GLR variant showing the highest efficiency. In adult C57BL/6 mice, the AAV9.NNR and AAV9.GLR variants showed broad expression of the eGFP reporter covering the entire fundus. Immunohistochemistry at three weeks after intravitreal injection of 1E+09 total vg showed high transduction of all retinal cell layers for AAV9.NNR, while AAV9.GLR staining showed strong transduction in the photoreceptor layer. Of note, both variants also showed strong transduction of the non-pigmented epithelium of the ciliary body in C57BL/6 mice. Currently, the most promising variants are being tested in human retinal organoids to further investigate their potential for gene therapy in a complex *in vitro* model of the human retina. In summary, we describe novel promising AAV9-based vectors with improved tropism that enable less invasive and potentially safer intravitreal gene supplementation therapy for retinal diseases.

1244 Pharmacology of Clinical Candidate Lipid Nanoparticle-Mediated mRNA-Based Therapeutics for Crigler-Najjar Syndrome Type 1

Vivek Chowdhary[1], Elizabeth Campbell[1], Karina Cuevas Mora[1], Rucha Fadnavis[1], Celensia Tolson[1], Grayson Sanchez[1], Jason Lamontagne[1], Christine Draper[1], Deirdre McMenamin[1], Elizabeth L. Buza[1], Kimberly Coughlan[2], Hannah Zhang[2], Paolo G. V. Martini[2], Jenny A. Greig[1], James M. Wilson[1]

[1]University of Pennsylvania, Philadelphia, PA,[2]Moderna, Cambridge, MA

Crigler-Najjar syndrome type 1 (CN1) is an ultra-rare disorder of bilirubin metabolism caused by mutations in the uridine diphosphate glucuronosyltransferase 1A1 (*UGT1A1*) gene. CN1 is primarily managed by phototherapy, which requires the individual to undergo 10-12 hours of therapy per day, impeding their quality of life. This study evaluated the pharmacology of a systemically administered clinical candidate lipid nanoparticle (LNP)-encapsulated human UGT1A1 (hUGT1A1) mRNA therapy in a *Ugt1* knockout mouse model. Newborn knockout mice were rescued from lethal postnatal hyperbilirubinemia by a single dose of LNP at 0.5 mg/kg, encapsulating the same hUGT1A1 mRNA. The rescued adult knockout mice then received a single injection of the clinical candidate LNP-encapsulated hUGT1A1 mRNA at a dose of 0.1 mg/kg, 0.5 mg/kg, or 1.0 mg/kg. Within 7 hours, serum total bilirubin levels decreased to wild-type levels (< 0.2 mg/dL) in the cohort dosed at 1.0 mg/kg, followed closely by the cohort dosed at 0.5 mg/kg in a dose-dependent manner. This reduction was sustained for 2 weeks in the highest dose cohort; subsequently, bilirubin levels rose and returned to pre-treatment hyperbilirubinemia levels by day 42 post-administration. In addition, we achieved sustained reductions in total serum bilirubin levels by repeated administration of the clinical candidate LNP-encapsulated hUGT1A1 mRNA at 1.0 mg/kg in a biweekly regimen for up to 12 weeks. Multiple doses of the LNP-encapsulated hUGT1A1 were well tolerated without any reduction in efficacy. No gross lesions were detected upon histopathological evaluation of the liver, kidney, or spleen. Findings in the liver consisted of minimal single hepatocyte necrosis (most consistent with apoptosis) with or without minimal-to-mild mononuclear inflammatory cell infiltrates. Overall, our results demonstrate that we can achieve wild-type bilirubin levels as early as 7 hours after injection of LNP-encapsulated hUGT1A1 mRNA at 1.0 mg/kg, suggesting that this may represent a potential treatment strategy for CN1.

1245 Towards Ultra Scale-Down AAV Production in Microtiter Plates

Vincent Wiegmann, Florian Dziopa

MeiraGTx, London, United Kingdom

In recent years, high-throughput screening methods have become an integral part of research and development in the biopharmaceutical industry. Due to their low cost, ease of operation and high degree of

parallelisation, microtiter plates remain an important format for early-stage process development with a strong track record of bioprocessing applications. Yet, few examples of viral vector production in microtiter plates have been published to date. This work describes the scale-down of a transient transfection-based adeno-associated virus (AAV) production process from 250 mL stirred tank reactor (STR) to 24 deep square well microtiter plates (24DSW), encompassing serotypes AAV2, AAV5, and AAV8. Initially, 24DSW material of construction and working volume were evaluated, resulting in comparable HEK293 growth kinetics to the 250 mL STR-scale. Subsequently, a Design of Experiment (DoE) approach was employed to further the understanding of the transfection step at the micro-scale. Finally, a scalable cell lysis step was demonstrated for all tested serotypes. Iterative process advances led to improved productivity, resulting in viral genome titres comparable to the 250 mL STR-scale and a reduction of the intra-plate coefficient of variance from 60% to under 30%, proving the suitability of the platform for large early-stage screening studies.

1246 Therapeutic Effects of hMSCs Administration in a Mouse Model of SCA2

Sehwan Kim[1], Youngpyo Nam[2], Hanwoong Woo[2], Sang Ryong Kim[2]

[1]School of Life Sciences, Kyungpook National University, Daegu, Korea, Republic of,[2]Brain Science and Engineering Institute, Kyungpook National University, Daegu, Korea, Republic of

We have investigated the therapeutic potential of human mesenchymal stem cells (hMSCs), transplanted intrathecally (IT), in a transgenic mice model bearing a polyQ mutation in the ataxin-2 gene. Our results showed that IT transplantation of hMSCs at 26 weeks old could induce a significant improvement of abnormal motor function, measured by the ataxic scoring system, shown in spinocerebellar ataxia type 2 (SCA2) mice until 24 weeks after hMSCs administration. In addition, we observed that hMSCs administration protected the loss of purkinje cells through production of neurotrophic factors such as brain-derived neurotrophic factor (BDNF) and glial cell line-derived neurotrophic factor (GDNF), and inhibition of cerebellar inflammatory responses by production of anti-inflammatory molecules such as tumor necrosis factor stimulated gene-6 (TSG-6) and Follistatin-like 1 (FSTL1), respectively. Altogether, the administration of hMSCs improved motor behavior and ataxia-pathology alleviation by stimulating endogenous regeneration and suppressing inflammatory responses. Notably, the results of this study strongly support further exploration of the feasibility to design new clinical approaches for SCA2 patients.

1247 Natural AAV2 Variants Demonstrate Stronger Neurotropism, Penetrance of the Blood-Brain Barrier, and Differential Transduction of Brain Regions Compared to AAV9

Sophia Liu[1,2], Thomas Leland[1,2], Manish Muhuri[1], Anoushka Lotun[1], Meiyu Xu[1], Guangchao Xu[3], Li Luo[3], Wanru Qin[3], Ran He[1], Qin Su[1], Jun Xie[1], Yu-Quan Wei[3], Phillip WL Tai[1,4], Guangping Gao[1,4]

[1]UMass Chan Medical School, Worcester, MA,[2]Co-first Authors, Worcester, MA,[3]Sichuan University, Chengdu, China,[4]Co-corresponding Authors, Worcester, MA

There is a continuing need to discover and/or engineer novel adeno-associated virus (AAV) capsids for human gene therapy. Most discovery pursuits are focused on overcoming the patient's immune system and delivering transgenes efficiently to specific tissue targets. Capsids of different serotypes possess diverse tropism profiles, resulting from variations in the amino acids present on the capsid surface. Multiple studies have used rational design to engineer capsids with desired transduction patterns. Random mutagenesis and machine learning approaches, coupled with directed evolution have enabled researchers to test large libraries of candidate capsids. These efforts have uncovered capsids that outperform those tested in clinical trials and commercially-approved AAV vectors. However, naturally circulating AAV variants remain an untapped reservoir for capsid discovery. Among a library of human-isolated 86 AAV2 variants that show equal or better packaging yields than prototypical AAV2, we identified seven variants tentatively named v46, v56, v67, v81, v224, v326, and v358, that demonstrated strong transduction following intrahippocampal injections in adult mice. In addition, we observed that the variants conferred differential transgene expression in separate structures of the hippocampus. These capsids possess 12-15 residues that are different from AAV2, mainly clustered within variable regions IV-VIII. Four of the seven capsid variants share variable region residues with AAV2.v66, a neurotropic AAV2 variant we previously identified. We have been exploring the mechanisms that underpin how these variants can confer neurotropism that rivals AAV9. Our preliminary data show that following facial vein injections of neonatal mice, the seven variants can traverse the blood-brain barrier and exhibit strong transduction of the thalamus, a structure that is an important target for neuronopathic lysosomal storage diseases but fails to be strongly transduced by AAV9 with systemic delivery. Our ongoing work explores whether the unique biodistributions achieved by our AAV2 variants are a result of cell type-specific transduction. Our findings support the notion that natural variants can serve as useful sources for gene therapy capsids.

1248 Modification of Conventional Mouse Dendritic Cells

Shelby Namen[1], Gaurav Pandey[1], Megan Harris[2], Daniel P. Miller[2], Samir Mendonca[1], David T. Curiel[1], Carl DeSelm[1]

[1]Department of Radiation Oncology, Washington University in St. Louis, St. Louis, MO,[2]MaxCyte, Gaithersburg, MD

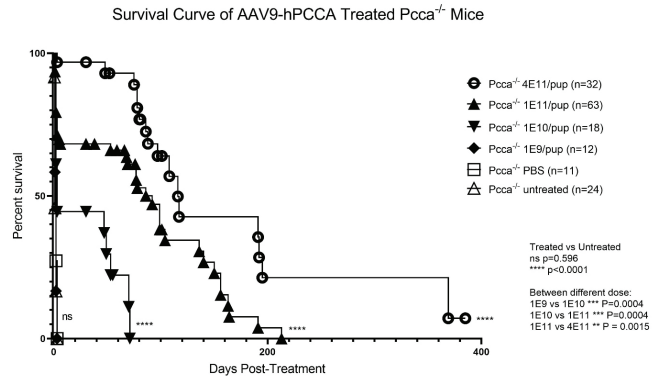
Dendritic cells play an important role in bridging the innate and adaptive immune response. Conventional dendritic cells (cDCs) are the most potent antigen presenting cell (APC) *in vivo*, but due to their relative scarcity and difficulty to culture, far less work has been done to optimize techniques for genetically modifying them relative to other myeloid cells, such as macrophages or monocyte-derived DCs. Here we aimed to develop and refine permanent and transient methods to modify/engineer mouse cDCs, so that they may be more effectively used in cancer immunotherapy and vaccine studies. We tested various viral transduction methods including two different adenoviral vectors (Ad5 and AdRGD) and a retroviral vector (SFG) using different promoters to improve expression. In addition, we compared and tested electroporation with DNA and mRNA using the MaxCyte ExPERT GTx. Optimized electroporation with mRNA yielded the greatest transfection efficiency (~90%) of all methods and was able to be maintained for up to 8 days, while optimized retroviral transduction yielded moderate transduction efficiency (25-50%) with long-term expression. The retroviral vector containing an additional shortened CD11c promoter had the greatest cDC1 transduction. Electroporation with DNA was able to modify cDCs (8-15%) but yielded poor cell viability. Ad5 transduced cDC1s at a low rate of ~2%, while AdRGD improved transduction by 20-fold, to 40%. These studies provide a variety of new methods for effectively engineering and modifying mouse cDCs.

1249 Systemic AAV9 Gene Therapy for Propionyl-CoA Carboxylase, Alpha Subunit (AAV9-hPCCA) in a Neonatal Lethal Model of Propionic Acidemia: Dose Finding, Biodistribution, and Long-Term Safety

Lina Li[1], Eun-Young Choi[1], Erik Wagner[2], Amy Wang[2], Xin Xu[2], The PaVe-GT Team[2], Randy J. Chandler[1], Charles P. Venditti[1]

[1]NHGRI, NIH, Bethesda, MD,[2]NCATS, NIH, Rockville, MD

Background: Propionic acidemia (PA) is an often lethal organic acidemia caused by deficiency of the enzyme propionyl-CoA carboxylase (PCC). PCC is ubiquitously expressed and comprised of α and β subunits encoded by either the *PCCA* or *PCCB* genes. Elective liver transplantation has been offered to severely affected patients and there are no approved therapies for the treatment of PA. Systemic AAV9 gene therapy could enable hepato-cardiac correction and provide a viable alternative to liver transplantation that might also ameliorate or prevent cardiomyopathy, a devastating complication of PA. **Methods:** To develop an AAV9 gene therapy to treat PA as an NCATS sponsored Platform Vector Gene Therapy (PaVe-GT) indication, we developed and then further studied an adeno-associated virus 9 (AAV9) vector expressing the propionyl-CoA carboxylase, alpha subunit (*PCCA*) cDNA under control of the elongation factor 1 alpha (EF1a) promoter in a neonatal lethal *Pcca* knock-out ($Pcca^{-/-}$) mouse model. The most efficacious vector, AAV9-hPCCA [NCATS-BL0746], was produced at research, 10L, and 50L scales for preclinic studies to determine in vivo efficacy, explore dose ranges, and establish manufacturability. $Pcca^{-/-}$ and control littermates were treated on day of life (DOL) 1 to across the doses of 1E9, 1E10, 1E11 and 4E11 GC/pup, equivalent to ~ 7E11, 7E12, 7E13 and 2.8E14 GC/KG, respectively. In mice that were sick, aged or recently found dead, dissection and gross examination with microscopic examination in representative treated animals were performed to assess the liver, heart, kidney, skeletal muscle, and brain. **Results:** Dose-dependency was noted, with 1E10 GC/pup emerging as the lowest dose that demonstrated a survival signal (see Figure). Treatment with the AAV9-hPCCA vector was accompanied by improvements in clinical, metabolic (reduced plasma 2-methycitrate levels), and enzymatic (restoration of 1-C^{13} propionate oxidation; increased hepatic and cardiac PCC enzymatic activity) parameters. A biodistribution study using ddPCR to detect the *PCCA* transgene in AAV9-hPCCA treated $Pcca^{-/-}$ mice quantitated vector transduction in various tissues, and subsequent RT-qPCR, Western blotting, and RNA in situ hybridization confirmed robust transgene expression, particularly in hepatocytes and cardiomyocytes in $Pcca^{-/-}$ mice and $Pcca^{+/-}$ controls. In the aggregate cohort of mice treated with the AAV9-hPCCA [NCATS-BL0746] (N=283), studied over an age range of DOL 1 to DOL 765, hepatocellular carcinoma (HCC) was not detected in any $Pcca^{-/-}$ mice (N=125) or $Pcca^{+/-}$ controls (N=158). **Conclusions:** Our studies establish a range of doses that demonstrate clinical efficacy of AAV9-hPCCA [NCATS-BL0746] in a severe disease model of propionic acidemia. Importantly we document that $Pcca^{+/-}$ control littermates, some treated with AAV doses as high as 2.8E14 GC/KG on DOL 1 and observed for as long as 765 days after injection, did not develop HCC, supporting our previous hypothesis that vector design is the dominant factor predisposing mice to develop HCC after AAV integration. The AAV9-hPCCA vector used here is potent in vivo, but the AAV-hPCCA vector genome is devoid of viral and or cellular enhancers and could be readily reconfigured to express another cDNA for high dose AAV applications to achieve excellent long-term safety and no genotoxicity.



1250 Genetic Assessment of Impurity in Human iPSCs for Cell Therapy Using CE- and NGS-Based STR Analysis

NaRi Seo, Ji-Hye Kim, Yoo Sung Kim, Jun Ho Yun, Hyunkeun Kim, Yoonjeong Lee, Sunhee Kim, Ki Dae Park, Misun Park

National Institute of Food and Drug Safety Evaluation, Ministry of Food and Drug Safety, Cheongju-si, Korea, Republic of

Background: The quality control of starting materials is critical for the stability and efficacy of the final products in cell-based therapy. The use of human induced pluripotent stem cells (hiPSCs) has been rapidly increased as a starting material for regenerative therapeutic intervention due to their pluripotency and large-scale manufacturing potential. One of the key concerns in hiPSC-based cell therapy is genetic stability and impurity in hiPSCs during subculture or cell banking. Recent MFDS guidelines recommend applying the Short Tandem Repeat (STR) analysis to assess the possibility of cross-contamination with other cells during the hiPSC manufacturing process, but robust method protocols remain to be verified. In this study, we established methods for genetic assessment of impurity in hiPSCs using Capillary Electrophoresis (CE)-STR and Next-generation Sequencing (NGS)-STR followed by comparative analysis of two methods with mixed-cell samples. Methods: For the assessment of impurity in hiPSCs, we used two types of stem cells; hiPSCs from the Korea National Stem Cell Bank and human induced neural stem cells (hiNSCs) from direct reprogramming of human fibroblast. The characteristic properties of hiPSC and iNSC were identified by real-time PCR and flow cytometry. To examine the sensitivity of CE-STR and NGS-STR, five mixed-cell samples were prepared using iPSCs and iNSCs from different genetic origins. Five mixed-cell samples were prepared with various ratios of 20%, 10%, 5%, 2.5%, and 1%. DNA concentration and quality of these five samples were assessed by Trio DNA Quantification Kit. CE-STR profiles were analyzed using Powerplex Kit and GeneMapper ID-X software. Precision ID GlobalFiler NGS-STR Panel v2 and Converge software v2.1 was used for NGS-STR profile analysis.Results: For the characteristic analysis of two stem cell types, we identified specific molecular marker genes in hiPSCs (OCT4 and Nanog) and hiNSCs (Pax6 and NCAD). To meet the QC criteria of genomic DNA for STR profile analysis, we confirmed that the genomic DNA from mixed-cell samples satisfied the criteria of DNA degradation index value (<1.5). When the STR profile matching percentage between mixed-cell samples and hiNSC is 56% or higher, it was defined as 'further analysis required'. In the CE-based STR method, up to 5% cell impurity (> 1:20 mixed-cell ratio) was detected, but 2.5% and 1% cell impurity (1:40 and 1:100 mixed-cell ratio, respectively) were undetected. For the NGS-STR method, we performed the QC of the library, confirming all the alignment parameters within QC satisfactory values. From the results of checking the total aligned bases using human genome hg19 as a reference, it was confirmed the sequencing was successfully performed with a value of 96% or higher. By using NGS-based STR analysis, unexpectedly, we could assess the impurity of cells when > 20% of cell impurity (> 1:5 mixed-cell ratio) existed in mixed-cell samples. The interpretation criteria are based on cell line discrimination criteria of the International Cell Line Certification Committee. Conclusion: In this study, we successfully established CE-STR and NGS-STR profiling methods which can be applied to a genetic assessment of impurity in hiPSCs using mixed-cell samples. Although NGS-STR can provide additional information on gene mutation in hiPSCs, we demonstrated that CE-STR could detect mixed cells with high detection sensitivity compared to NGS-STR. Taken together, it is necessary to choose which of two methods to apply for the assessment of impurity in starting cells according to the purpose.

1251 A Modular System to Convert Therapeutic miRNA Expression Cassettes from Ubiquitous RNA pol III-Based Promoters to RNA pol II-Driven Tissue-Specific Promoters While Maintaining Fidelity of Processing and Efficacy

Noah K. Taylor[1], Matthew J. Guggenbiller[1], Scott Q. Harper[2]

[1]Nationwide Children's Hospital, Columbus, OH,[2]Ohio State University & Nationwide Children's Hospital, Columbus, OH

Dominant genetic diseases may benefit from RNA interference (RNAi)-based gene therapies. Although RNAi was discovered around 1998 and many RNAi-based gene therapies have been under development since that time, the approach is still emerging translationally and clinically. Many RNAi-based systems rely upon first-generation expression strategies that employ ubiquitous RNA polymerase III (pol III)-driven promoters, such as U6 or H1, to drive shRNA or miRNA expression in vivo. These systems are advantageous because they produce primary miRNA transcripts from defined transcription start and termination sites, thereby enabling consistent processing of predictable mature products through endogenous miRNA biogenesis pathways. However, these pol III-based systems do not allow cell- or tissue-specific expression. Commonly used tissue-specific promoters utilize RNA polymerase II (pol II) to drive transcription. These pol II-based systems often have multiple transcription start sites and require poly A signals and transcript poly-adenylation for termination. As a result of these sequence differences, converting a pol III-driven miRNA to a pol II-driven system can change the secondary structure of the primary miRNA transcript, thereby altering the maturation process by the RNAse enzymes Drosha and Dicer. This is important because even a single nucleotide change in a mature miRNA or shRNA sequence can impact specificity and efficiency. Thus, converting an existing pol III-based miRNA expression system to one driven by RNA pol II, and still producing the same mature miRNA, can be challenging. We previously developed and reported U6- and H1 promoter-driven systems to express therapeutic miRNAs targeting several dominant disease genes. In this study, we generated several novel miRNA designs to convert an existing U6 promoter-driven miRNA to a tissue-specific, pol II-based system. We incorporated novel secondary structure elements in the primary transcript regions flanking Drosha and Dicer processing sites, and confirmed efficacy and expression of the mature sequences in vitro. Our system will allow rapid conversion of ubiquitous to tissue-specific miRNA expression systems without rederivation of lead RNAi triggers, while also providing a new approach to restrict expression of therapeutic miRNAs.

1253 AAV Capsid Comparison in Human Neuronal Cells

Lu Song, I-Chueh Huang, Steven Pennock, Marshall Huston, Thomas Wechsler, Justin Scheer

Janssen Research & Development, The Janssen Pharmaceutical Companies of Johnson & Johnson, Brisbane, CA

Gene therapy is emerging as a promising approach for treating a spectrum of neurological and neurodegenerative disorders, including Alzheimer's disease, Parkinson's disease, and amyotrophic lateral sclerosis. Adeno-associated viruses (AAVs) have been used as efficient tools for clinical gene delivery in various genetic disorders with neurological manifestations. Over a dozen AAV serotypes have been identified by natural discovery and novel capsid variants are being created by rational design and directed evolution. AAV serotypes have distinct tropisms due to their affinity to the receptors on the target tissues or cells. There are still limited platforms for evaluating AAV serotypes in human neuronal cells. Here, we establish an *in vitro* strategy to understand AAV tropism in human neuronal cells, including neuroblastoma cells and differentiated neurons derived from induced pluripotent stem cells (iPSC). We transduced the neurons and neuroblastoma cells with multiple AAV serotypes. Our results indicate that AAV serotypes have different capacities to transduce neuronal cells. These findings may contribute to AAV capsid selection in gene therapy applications to treat neuronal-related disorders.

Friday Poster Session

1254 Scalable Continuous Flow Iodixanol Gradient Ultracentrifugation Purification of Supernatant Derived rAAV8 with Enhanced Purity When Compared to Batch CsCl Gradient Ultracentrifugation

Gael Mbele[1], Chiara Piscopo[1], Lakshmikanth Gandikota[1], Monica Doria[1], Sandra Merino[2]

[1]Innovavector srl, Pozzuoli, Italy,[2]Alfa Wassermann Separation Technologies, West Caldwell, NJ

Adeno-associated virus (AAV) is one of the most promising gene therapy vectors due to their low immunogenicity and large tropism. A robust, reliable and scalable purification process for AAV vectors is essential to the gene therapy industry. AAV purification techniques can be separated into two distinct categories, namely density gradient centrifugation or chromatography purification. For the serotype-independent purification of AAV vectors produced in HEK-293 or SF9 cells, the two most widely established methods for preclinical applications are based on batch ultracentrifugation using either cesium chloride (CsCl) or an Iodixanol density gradient. Importantly, Iodixanol is inert and non-toxic to mammalian cells, and should be favored for scaling up. In addition, Iodixanol has sufficient viscosity to form a stable gradient. Reported data suggest that vectors based on many commonly used AAV serotypes are present at high titer in culture medium of transfected cultures, and can be recovered simply by harvesting and concentrating the culture fluids. Here, we report a simplified and scalable rAAV8 vector manufacturing process using supernatants of triply transfected HEK 293 cultures and PEG precipitation strategy. To this end, we compare the final product profiles obtained : 1) via 2 rounds of CsCl gradient-based batch ultracentrifugation and 2) 1 round of Iodixanol gradient-based continuous flow zonal ultracentrifugation. Data obtained shows the presence of a significant quantity of rAAV8 viral particles in the supernatants of the cell cultures. This quantity is similar to one that can be obtained after cell lysis. A significant improvement of impurities profile (decrease of residual total host cell protein and cellular DNA) in the final product has been observed after purification through Iodixanol gradient performed using continuous flow ultracentrifugation with respect to the one obtained after cesium chloride gradient batch ultracentrifugation while total particles recovery (process efficiency) and vector purity are similar in both purification processes. Due to its high capacity and scalability these data suggest that supernatant derived rAAV purified with one round of Iodixanol gradient-based ultracentrifugation could be a suitable process for producing enough material for clinical application in cost and time effective way.

1255 The Impacts of Suppressing Cellular Innate Immune Responses on Adeno Associated Virus Yields During Production

Paul Kroeger[1], Khan Umaer[1], Ngan Trinh[1], Andrea Vervoort[2], Srivanya Tummala[1], Ben McLeod[2], Brian Tomkowicz[1]

[1]Viral Vector Research & Development, Center for Breakthrough Medicines, King of Prussia, PA,[2]Virica Biotech, Ottawa, ON, Canada

Cellular immune response to viral infection, as well as neutralization due to pre-existing antibodies, are significant clinical hurdles to overcome for successful viral vector mediated therapies. However, very little attention has been placed on understanding how the cellular innate immune response impacts recombinant AAV production during manufacturing. It has been recently reported that during the triple transfection process, a common technique employed for recombinant AAV generation, indeed, a multi-phasic innate response, accentuated by upregulation of inflammatory, antiviral, and interferon-stimulated cytokines genes and proteins is prominent in HEK293 production cells. In a collaboration between Virica Biotech and the Center for Breakthrough Medicines, we sought to better understand how suppressing the cellular innate response would impact virus production using Viral Sensitizers (VSE™). VSEs are proprietary small molecules that are designed to target cellular immune responses with the overall outcome of improving viral yields and effectiveness. VSEs accomplish this by transiently altering cell signaling to improve yields. Virica Biotech has a library of hundreds of VSEs each of which attenuate the antiviral defense in different ways. We screened eight compounds representing unique classes of antiviral defenses and identified several VSEs that increase overall virus and full particle production, as measured by dPCR & ELISA, in small-scale, 30mL screens. Identification of leads that showed optimal performance were then used in shake flask studies to examine the impact these compounds have on the distribution of full particles following purification using a two-step AKTA-based affinity and anion-exchange polish. Our results

demonstrate that the addition of viral sensitizers skews particle yields to a "full" phenotype, in agreement with published observations that cellular innate immune responses impact virus production.

1256 Evaluation of the Manufacturability of MyoAAV Capsid Variants

Harvir Grewal, Tamera Toland, Nathan Jones
Kate Therapeutics, San Diego, CA

Directed evolution of adeno-associated virus (AAV) capsids has the potential to drive exciting breakthroughs for tissue-specific gene therapies. The advantages of these novel capsids are in their ability to target specific cell types with high efficiency resulting in a significantly lower dose required to elicit a therapeutic benefit compared to natural capsids. However, these same capsid surface modifications that alter tropism and potency may also affect the manufacturability of the vector, i.e., impact productivity, purification, and stability. The incompatibility of novel capsids with an established manufacturing platform can result in extended process development timelines, thereby delaying access of transformative therapeutics to patients. Therefore, early determination of manufacturability can either de-risk a development candidate or aid resource allocation planning. Moreover, although biodistribution and biological activity will ultimately define the selection of a novel capsid, performing a manufacturability assessment as part of a comprehensive capsid engineering and screening exercise can aid in the selection of an ideal capsid variant for clinical development. The Directed Evolution of AAV capsid Leveraging In Vivo Expression of transgene RNA (DELIVER) platform is a methodology to select highly potent AAV capsid variants with ability to transduce specific cell types through the application of directed evolution and machine learning. The DELIVER methodology begins with a library of >5,000,000 capsid variants in the first round of selection; yielding approximately 30,000-60,000 variants introduced in the second round; and resulting in the identification of 10-30 primary capsid variants. These primary capsid variants are evaluated for manufacturability in parallel to the final round of screening. We have implemented a manufacturability strategy that applies metrics for assessing productivity in suspension culture, compatibility with affinity-based purification processes, and consistent product quality attributes. The productivity of candidate capsid variants was determined using a scale-down model of a suspension-adapted HEK293 transient transfection process. Cultures were harvested by chemical lysis, clarified by centrifugation, and processed by affinity chromatography. All process parameters were held constant for each capsid variant for the preliminary assessment. Samples post-lysis, post-clarification, and post-chromatography were analyzed by ddPCR to determine vector titer. Multiple MyoAAV capsid variants were tested within the manufacturability paradigm. All variants demonstrated similar productivity in cell culture harvest at quantities sufficient to support clinical development. Further, all variants bound and eluted from an AAV9 affinity column using standard conditions. Each variant also demonstrated expected quality attributes for AAVs (e.g. capsid protein ratio, capsid size, etc.). The totality of the data generated during the assessment showed similar manufacturability for all MyoAAV variants tested - suggesting that insertion of peptide sequences in variable region VIII does not significantly alter the productivity in HEK293 cells, nor impact vector quality.

1257 Bench Scale Process Development of RNA-LNPS Using a Novel Microfluidics Platform

Ian Johnston[1], B. MacDougall[1], Suraj Abraham[2], P. Harvie[2], Sri Abbina[3], Anitha Thomas[2], Aruna Balgi[2], Stella Park[2], C. Ong[2], Keara Marshall[2], Vicki Stronge[3], A. Ugorenko[4], Yvonne Perrie[4], Samuel Clarke[2], Ian Villamagna[1]
[1]Precision NanoSystems Inc., Vancouver, BC, Canada,[2]Precision NanoSystems, Vancouver, BC, Canada,[3]Precision Nanosystems, Vancouver, BC, Canada,[4]University of Strathclyde, Glasglow, United Kingdom

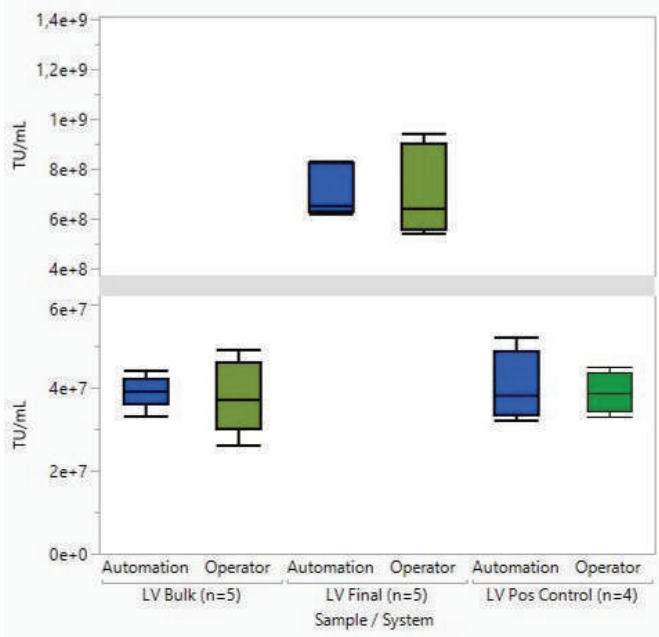
Introduction: The RNA-lipid nanoparticle (LNP) vaccines for the SARS-CoV-2 pandemic highlight the impact of genetic medicines deployed at scale. RNA-LNP applications also include gene editing, oncology, and rare diseases. However, a common need for these RNA-LNP therapies is a scalable manufacturing process. The mixing process to encapsulate RNA within LNPs is among the most difficult unit operations to scale-up throughput rates and batch sizes. In this work, we demonstrate the capabilities of a novel microfluidic-based instrument that enables bench scale production of 60 mL of pre-dilution RNA-LNPs at flow rates of 200 mL/min. These capabilities allow rapid and cost-effective process development with the same critical process parameters (CPPs) and downstream unit operations that are used for large-scale cGMP production. **Methods:** Self-amplifying mRNA (saRNA) encoding the SARS-CoV-2 spike protein and a custom lipid composition were used as a model for a RNA-LNP vaccine. The total flow rate and formulation volume was increased stepwise from 12 mL/min and 5 mL to 200 mL/min and 40 mL using the NanoAssemblr Ignite+ instrument with the standard NxGen microfluidic mixer or larger NxGen 500 mixer. Post-formulation dilution ratio, N/P ratio, and flow rate ratio were kept constant. The saRNA-LNPs were purified with ultrafiltration or TFF. Size, polydispersity and zeta potential were measured by DLS, and RNA encapsulation efficiency by Ribogreen assay. The lipid composition of the saRNA-LNPs was assayed with UHPLC. The saRNA integrity was assayed through capillary gel electrophoresis. *In vitro* expression was assessed in BHK570 cells. Immunization was done by intramuscular injection, with a booster on day 28. Tail bleeds were 1 day before each immunization and mice were culled on day 42. IgG titers were determined by ELISA. **Results:** All the saRNA-LNPs were of high quality with particle sizes ranging from 75 - 87 nm, polydispersity indices < 0.16 and RNA encapsulation efficiency > 95%. *In vitro* spike protein expression was similar across all process conditions with EC50 values between 0.06 to 0.12 μg/mL. Immunization of mice with the saRNA-LNPs resulted in an IgG specific response between $1.4x10^4$ to $1.8x10^5$ ng/mL. Additionally, the 40 mL batches enabled downstream processing by TFF. Finally, the saRNA-LNPs were similar to those produced by larger clinical-scale instruments. **Conclusions:** We have developed a microfluidic instrument and workflow for enabling bench scale process development of RNA-LNP drugs with the same CPPs used for GMP production. Sufficient quantities of these RNA-LNPs can be produced for optimizing downstream unit operations such as in-line dilution and TFF, and for large cohort animal studies, stability testing and extensive analytical

characterization. Overall, this technology should enable researchers to begin process development activities much earlier in drug development, thereby decreasing cost, risk, and timelines.

1258 Automated Systems Leading Solution to Increase LVV Characterization Capacity

Giuliana Vallanti[1], Margherita Neri[2]
[1]AGC Biologics, Milan, Italy,[2]AGC Biologics, Milano, Italy

AGC biologics is a leading CDMO, providing world-class development and manufacture of therapeutic proteins, plasmid DNA, viral vectors and genetically engineered cells. Lentiviral vectors (LVV) are efficient vehicles for gene delivery that play an important role for ATMPs. The efficiency of the production process and the performance of the final LVV is monitored through potency and purity methods. In AGC Biologics, the infectious and physical viral titers and the ELISA assays to determine residual Host Cell Proteins, total residual DNA and residual Benzonase have been automated to increase capacity while also allowing the flexibility to run different assays in parallel using the same sample aliquot. The automated stations are constituted of a core liquid handling, full integrated with all the devices, Sealers, Real Time PCR thermocyclers, plate wash and plate reader, incubators to correct perform the different steps of the assays, including standards, controls and samples dilutions, procedure steps, results analysis. The methods have been validated according before being transferred into automation and comparability of each assay's automated and manual methods has been demonstrated, with p values ranging from 0.800 to 0.090, repeatability ≤ 20% and a reproducibility with manual execution system ≤ 19%. Among the assays mentioned above, the infectious viral titer method is the most complex and time-consuming method, where the automation has brought the greatest help in terms of number of samples analysed at the same time. The assay is based on the detection of proviral DNA copy number integrated into the cell genome. The selected reference cell line, deeply characterized and full representative of target primary cells, is transduced with serial dilutions of vectors and tested with a qPCR assay. Regarding infectious titer, the automated solutions brought to 5-fold increase in number of samples daily tested, greatly reducing the timing of analysis and operator effort. Results generated with automatic stations on different purification steps or final purified LVV are comparable to the manual ones, Figure 1, with a repeatability ≤ 15% and a reproducibility with manual execution system ≤ 19%. All the automated stations, compliance to CFR21 and qualified according to ICH Q2 (R1), allow to have a complete automatic and traceable flow, from sample vial to result, that makes the difference in laboratory capacity. **Figure 1**. Representative data obtained from the comparability study. Reference cell line has been transduced with LV bulk (n=5), LV final product (n=5) or LV positive control of transduction (n=4) in independent experiments. The same samples have been processed either with automation or with the validated method. Results of the same sample have been analysed with pooled t-test assuming equal variance. The two data sets are not significantly different for all the samples tested (p ≥ 0.787).



1259 Engineering CRISPR-Based Editors for Treatment of Machado-Joseph Disease

Pedro Perdigão[1,2], Miguel Dias[1,2], Sara Lopes[1,2], Rita Fernandes[1,2,3], Frederico Pena[1,2,3], Miguel Lopes[1,2,3,4], Rui Nobre[1,2,4], Thomas Gaj[5,6], Luis Pereira de Almeida[1,2,7]

Woese Institute for Genomic Biology, University of Illinois, Urbana-Champaign, IL,[7]Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal

Machado-Joseph Disease (MJD) is a dominantly inherited neurodegenerative disorder, integrating the group of polyglutamine (polyQ) diseases as the most prevalent form of spinocerebellar ataxia. MJD is caused by the overexpansion of a cytosine-adenine-guanosine (CAG) trinucleotide repeat in the *ATXN3* gene encoding the Ataxin-3 deubiquitinase. As a result, the formation of an expanded polyQ segment within Ataxin-3 confers a toxic gain-of function to this mutant isoform manifested by the generation of protein microaggregates and toxic species that trigger neuronal cell death by disrupting vital cellular mechanisms. Suppression of *ATXN3* expression by RNA interference sequences is the most widely adopted approach to treat MJD. However, the role of Ataxin-3 in numerous cellular functions may be indicative that fully silencing its activity could be deleterious to patients. Here, we harnessed the ability of CRISPR-base editing technology to target the *ATXN3* genomic locus and precisely insert A>G or C>T point mutations to permanently remove the MJD-causing polyQ segment from the Ataxin-3 while keeping its physiological activity. For this purpose, we designed CRISPR-base editor sequences that (i) modulate

ATXN3 splicing to exclude the CAG-encoding exon 10 by disrupting conserved nucleotides within splicing sites, or (ii) introduce nonsense mutations to create premature stop codons in the exon 9 upstream of the CAG tract. We show that CRISPR-base editors can precisely insert single point mutations in the *ATXN3* locus with up to 70% efficiency, both in HEK293T cells or patient-derived induced pluripotent stem cells (iPSC). This results in the formation of a C-terminal truncated Ataxin-3 isoform lacking the polyQ tract previously reported to retain its ubiquitin-binding and deubiquitase activity. *ATXN3*-targeting base editing sequences were successfully packaged into a dual adeno-associated virus (AAV) vectors that efficiently reconstitute the CRISPR editor framework by intein-mediated protein trans-splicing. The capacity of CRISPR-base editors to edit *ATXN3* and rescue MJD neurodegeneration is currently being validated in patient iPSC-derived neuronal cultures and a transgenic mouse model. Our work illustrates the potential of CRISPR-base editors as a novel and safe gene therapy approach that could positively impact the life quality of MJD patients.

1260 High-Resolution Genetic Stability Analysis in Human Induced Pluripotent Stem Cell-Derived Cardiomyocytes for Cell Therapy

Jun Ho Yun, Ji Won Park, Su Ji Bae, Hyunkeun Kim, Yoonjeong Lee, Ki Dae Park, Sunhee Kim, Misun Park

National Institute of Food and Drug Safety Evaluation, Ministry of Food and Drug Safety, Cheongju-si, Korea, Republic of

Background: The use of human-induced pluripotent stem cell (hiPSC) as a starting material for cell therapy has been increased due to its pluripotency and large scale-manufacturing potential. However, the genetic stability of hiPSCs and their differentiated target cells have to verify since certain genetic variants could be associated with an increased risk of tumorigenicity or dysfunction for regenerative therapeutic intervention. In this study, we assessed the genetic stability of hiPSCs and hiPSC-derived cardiomyocytes (CMs) during the proliferation and differentiation process using next generation sequencing (NGS)-based analysis. Methods: To examine the genetic stability of hiPSCs or hiPSC-CMs, we performed CytoscanHD array and NGS-based analysis such as whole exome sequencing (WES), targeted (tumor) panel sequencing (TS) at 0, 2, and 4 weeks after differentiation of hiPSCs into hiPSC-CMs. For the prediction of tumorigenicity from genetic mutations in hiPSCs and hiPSC-CMs, we analyzed the mutation data using COSMIC (Catalogue of Somatic Mutation in Cancer), reflecting a high risk of cancer mutation. We further analyzed their functional and structural pathogenicity using multiple bioinformatics tools including Mutation Taster software. Results: First, we detected a total of 25 sub-chromosomal copy number variations (CNVs) with sizes ranging from 7.3 kb to 2.5 Mb including 3 deletions and 22 gains in the process of sub-culture of hiPSCs and differentiation into hiPSC-CMs by NGS-based analysis. On chromosome 20 q11.21, copy number gain was detected with the size of 2.5 Mb CNV which was not detected by conventional karyotyping. Next, using WES analysis, we detected 425 of single base pair mutations which were found only in hiPSC-CMs at 2 and 4 weeks of differentiation from hiPSCs. Among those variants, three mutations were verified as a high risk of tumorigenicity with nonsense mutation or frameshift mutation. MUC4 c.8032_8033insA; p. (Pro2678fs) and KMT2C c.2263C>T; p. (Gln755Ter) were analyzed to be associated with potential tumorigenicity. AKAP9 c.4004_4006dupAA; p. (Lys1335_leu1336insGln) could be associated with potential abnormal myocardium. From the results of targeted (tumor) panel sequencing, we detected additional two genetic mutations such as BCOR c.1487_1500del; p. (Ile496AsnfsTer17) and BCOR c.2457_2460del; p. (819AsnTer) that could not be found by WES due to read depth differences. Conclusion: In this study, we demonstrated that the tumorigenicity-related genetic variants could be detected during the differentiation of hiPSCs into hiPSC-CMs by using various NGS-based analyses. The high-risk tumorigenic mutations were detected by only high-resolution analysis such as WES and TS, but not by conventional karyotyping. These results suggest that a high-resolution genetic analysis followed by an orthogonal validation method is not optional for assessing the genetic stability of hiPSC and hiPSC-derived target cells for cell therapies.

1261 Restoration of Brain Cholesterol Metabolism as Gene Therapy Strategy in Huntington's Disease: Unilateral Injections Are Insufficient to Elicit a Treatment Effect in HD Mice

Enejda Subashi[1], Haniyeh Yousef-Zadeh[1], Steve Cottin[1], Daniel Kemp[2], Alain Lamontagne[2], Michael O'Callaghan[2], Meredith Schultz[2], Lisa Aimone[2], Sandro Alves[1], Nathalie Cartier[1]

[1]Brainvectis SAS - Asklepios BioPharmaceutical, Inc, Institut du Cerveau (ICM), Paris, France,[2]Asklepios BioPharmaceutical, Inc, Research Triangle Park; Durham, NC

Impaired brain cholesterol metabolism is commonly identified in severe neurodegenerative disorders. In Huntington's disease (HD), impaired brain cholesterol homeostasis is caused by mutant Huntingtin (mHTT) deposition and is a major driver of HD hallmarks. Cholesterol 24-hydroxylase (CYP46A1), a key neuronal enzyme of cholesterol metabolism, is reduced in HD patients' brains. CYP46A1 removes the excess of cholesterol from neurons, thus regulating cholesterol synthesis and content in cell compartments. CYP46A1 is also is a key neuronal stress response factor in pathological conditions. In HD, reduced CYP46A1 is associated with extensive cholesterol accumulation in neuronal membranes with multiple consequences: impaired vesicular transport and synaptic transmission, compromised clearance of misfolded mHTT and compromised energy metabolism. Preclinical studies have indicated that restoring CYP46A1 levels and thus re-establishing cholesterol metabolism in striatal neurons by mean of an Adeno-Associated Virus (AAV) vector, considerably alleviated neuronal dysfunction and lowered mHTT accumulation through improved autophagy (Boussicaut et al. 2016; Kacher et al. 2019). In this study, we aimed at comparing the outcome of unilateral vs bilateral administration of AB-1001 (AAVrh10-CYP46A1) on motor and neuropathological outcomes in order to support, unilateral vs bilateral administration of AB-1001 in HD patients. The general locomotor activity (openfield) demonstrated no significant differences between R6/2 mice injected unilaterally or bilaterally with AB-1001 relatively to control R6/2 mice. The cylinder test revealed no differences among R6/2 mice injected with AB-1001 unilaterally or bilaterally, compared to R6/2 mice, also indicating the absence of forelimb asymmetry in mice

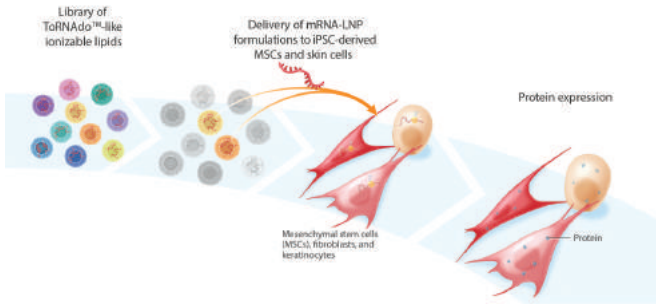
injected unilaterally. However, motor coordination analysis assessed by rotarod, showed that AB-1001, when administered unilaterally in R6/2 striatum up to titer 1.1E9 vg/µL (highest dose concentration in the human trial), did not improve motor performance of R6/2 mice. Bilateral intra-striatal AB-1001 delivery confirmed the beneficial effects of AB-1001 found in previous dose-response studies: motor performance of R6/2 mice injected bilaterally with AB-1001 at lower dose concentration (0.6E9 vg/µL) was improved by 60%.Interestingly, in R6/2 mice injected unilaterally with AB-1001, a significant reduction of aggregate number was observed [titers 0.6E9 vg/µL (25%) and 1.1E9 vg/µL (28%)] in injected striatum, accompanied with slight non-significant decrease (15-17%) in the contralateral non-injected hemisphere, despite the absence of vector genomes observed in that hemisphere. In R6/2 mice injected bilaterally with AB-1001 at 0.6E9 vg/µL, a comparable decrease on the number of aggregates (28%) was observed in both hemispheres. Neurofilament light-chain (NfL) levels (marker of neuro-axonal damage) remained unchanged in R6/2 mice injected unilaterally with AB-1001 at 0.6E9 vg/µL while a decreased trend was observed in mice injected unilaterally with the highest titer of AB-1001 (1.1E9 vg/µL; no motor benefits) and in R6/2 mice injected bilaterally with AB-1001 injected at lower titer (0.6E9 vg/µL), compared to control R6/2 mice. There were no adverse effects after unilateral/bilateral dosing of R6/2 mice with AB-1001. These data support that bilateral injections are beneficial for obtaining a clinical therapeutic effect of AB-1001 and that unilateral injections are insufficient in eliciting a treatment effect

1262 Novel Ionizable Lipids Derived from 2-Hydroxypropylamine and Spermine for mRNA-LNP Delivery

Ariadna Lubinus[1], Joseph Pisano[1], Elizabeth Belcher[2], Christopher B. Rohde[1], Matthew Angel[1]

[1]Factor Bioscience Inc., Cambridge, MA,[2]Eterna Therapeutics Inc., Cambridge, MA

Lipid nanoparticles (LNPs) containing cationic or ionizable lipids offer several advantages compared to other vehicles for nucleic acid delivery and have seen expanded clinical use with the introduction the COVID-19 mRNA vaccines and in treatments for genetic diseases. However, poor targeting, insufficient cellular uptake, and low endosomal release currently limit the use of lipid nanoparticles as efficient delivery systems for next-generation gene therapies. To address these limitations, we designed, synthesized, and formulated novel ionizable lipids as LNPs to optimize mRNA delivery to cells. We developed a library of 12 ionizable lipids containing hexyl 2-hexyldecanoate lipid tails and hydrophilic headgroups derived from spermine or 2-hydroxypropylamine. Nanoparticle formulations incorporating these ionizable lipids were prepared at a molar ratio of 50:38.5:10:1.5 (ionizable lipid: cholesterol: DSPC/DOPE: DMG-PEG_{2000}) with mRNA encoding GFP at an N/P ratio of 3. For all the lipids tested, a mean diameter ranging from 100-150nm was measured by DLS. All of the lipids showed encapsulation efficiencies between 70-80%, comparable to LNPs formulated using FDA-approved lipids ALC0315 and DLin-MC3-DMA. LNPs were administered to iPSC-derived MSCs, primary human fibroblasts, and keratinocytes. Microplate imaging showed peak GFP fluorescence between 40- and 48-hours post-transfection. We identified novel ionizable lipids that produced LNPs exhibiting lower mean particle sizes, higher loading efficiencies, and enhanced GFP expression compared to LNPs incorporating ALC0315 or DLin-MC3-DMA. These results indicate that lipids containing elements of spermine and 2-hydroxypropylamine headgroups may serve as components of next-generation, lipid nanoparticle-based gene therapies and assist in the rational design of ionizable lipids for mRNA delivery.



1263 Correcting Multi-Exonic DMD Deletions Using a CRISPR/Cas9- Based Knock-In System

Sina Fatehi Someeh

Genetics and Genome Biology, The Hospital for Sick Children, Toronto, ON, Canada

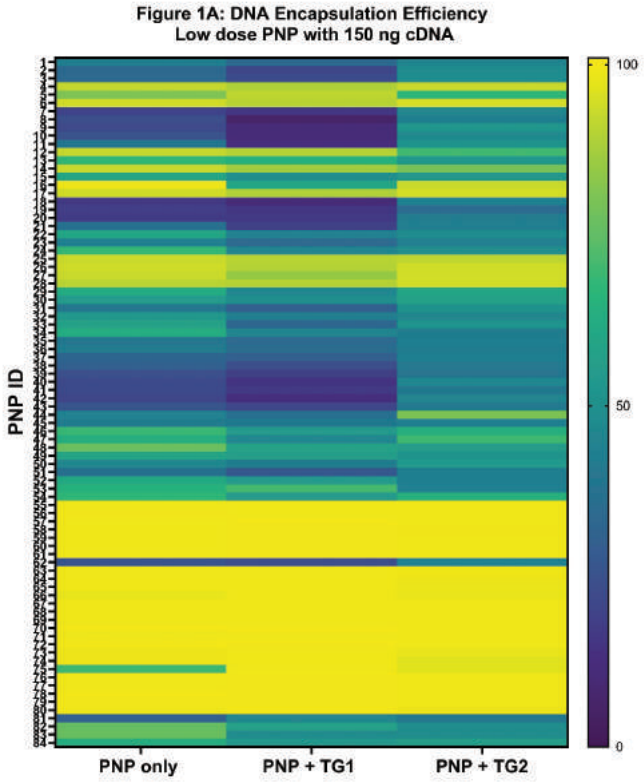
Duchenne muscular dystrophy (DMD) is the most common pediatric muscular dystrophy, with an incidence rate of 1 in 5,000 males due to its recessive X-linked mode of inheritance. Multi-exonic deletions that disrupt the open reading frame of the gene and stop dystrophin synthesis are the most common cause of the condition. The absence of dystrophin causes damage to build up in muscle cells during periods of contraction and relaxation. Continuous damage leads to increased muscle wasting in cardiac and skeletal muscles, significantly reducing life expectancy. A curative therapy for DMD deletions is within reach due to advances in CRISPR/Cas genome editing tools. We propose a novel strategy using these systems to correct the *DMD* patient deletion of exons 52-54 through targeted DNA knock-in of the deleted exons, termed homology-mediated end-joining (HMEJ). The proposed system was initially tested *in-vitro* on mouse myotubes harbouring the *Dmd Δ52-54* deletion followed by transition to a mouse model harbouring the same mutation. In both models, we have observed significant restoration of the wildtype transcript and dystrophin-positive fibres. The results of this project will demonstrate the efficiency of this gene editing strategy and determine its therapeutic capacity.

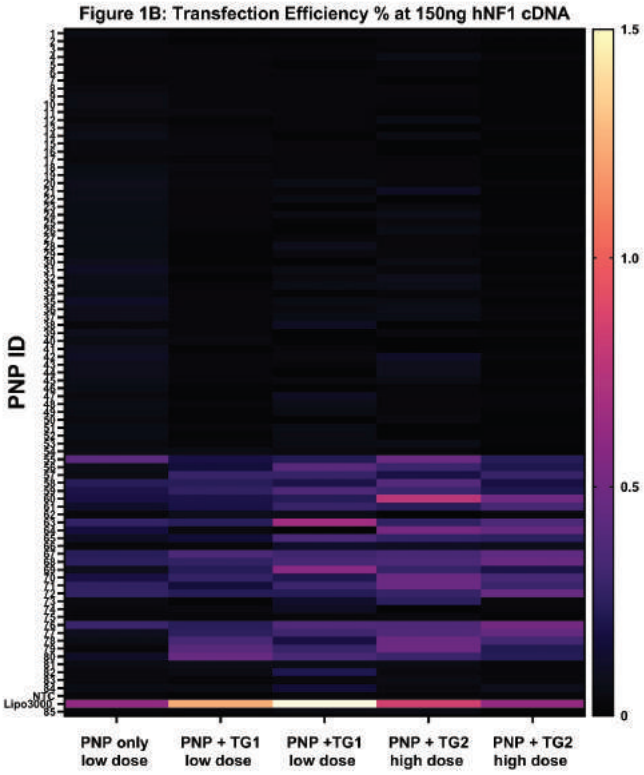
1264 Cationic Diblock Polymeric Nanoparticles Encapsulate and Deliver a Full-Length 20 kb cDNA to Neuronal Cells

Cherry Gupta[1], Ashlee Colbert[1], Caleb Hillrich[1], Joe Geers[1], Molly Kaufman[1], Emma Schmitz[1], Danielle Huk[1], Michael Riedl[1], Allison Secard[1], Joanna Hoy[1], Nick Andrioff[1], Miguel Pedrozo[1], Smith Brian[1], Andrea McCue[1], Deeann Wallis[2], Robert Kesterson[3]

[1]Battelle, Columbus, OH,[2]UAB, Birmigham, AL,[3]Pennington Biomedical Research Center, Baton Rouge, LA

Reconstituting functional proteins via exogenous cDNA delivery to treat genetic diseases such as Neurofibromatosis 1 (NF-1) presents a promising treatment modality which, due to its wide applicability, has high potential for near-term clinical translation. This is currently blocked because of the lack of a suitable delivery vector that can encapsulate the large NF1 cDNA, which at 8.5 kbp is out of reach for viral vectors. In addition, there are no existing strategies that can achieve safe systemic targeted delivery to cells such as Schwann cells (SC) in the nervous system. To overcome these challenges, we used self-assembled cationic di-block polymeric nanoparticles (PNP) to encapsulate and deliver the NF1 cDNA plasmids to SCs *in vitro*. The key advantages of the PNPs proposed here are: large cargo capacity, access to extensive structural diversity, ability to be functionalized for targeting, ease of preparation, and stability during storage. A newly developed human NF1 cDNA plasmid (19553 bp) was used as cargo. This hNF1 plasmid contains a previously described NF1 cDNA with mini-intron under the CMV promote in the pCEP4 vector backbone and also encodes for a 2A-eGFP such that it expresses GFP. Further, a human telomerase reverse transcriptase (hTERT) immortalized primary human NF1 null SC line [CRISPRed out NF1 (ipn97.4 #24 NF1 -/-)] was used for all *in vitro* testing to ensure clinical relevance. Six different monomers with varying logP and pKa values were used to design a diverse combinatorial library of hundreds of PNPs with both active and passive targeting functionalities. A high-throughput synthesis and screening platform was used to test the PNPs *in vitro* in Schwann cells. cDNA loading efficiency was characterized using a RiboGreen dye exclusion assay. Transfection efficiency was quantified by analyzing cells with positive GFP expression on flow cytometry and cytotoxicity was quantified using a live-dead stain. Our results demonstrate that the cDNA encapsulation efficiency and transfection efficiency of the PNPs in the Schwann cells was modulated by the following factors: molecular weight, monomer type, monomer pKa, and the cDNA to PNP mass ratio. A subset of our PNP library, represented in the bottom 1/3 of Figure 1A and Figure 1B were best at encapsulating the cDNA and transfecting Schwann cells *in vitro*. Figure 1 shows heat maps of the cDNA encapsulation efficiency and transfection efficiency for the PNP library with passive and two active targeting groups (TG1 and TG2). The cell viability was over 90% for all tested PNPs. The results presented here provide a basis for future optimization of polymeric delivery vectors that can transfect this challenging cell target and point to an exciting opportunity for the field of non-viral gene delivery in general and neuronal cells in particular.





1265 Cardiac AAV Gene Therapy is Enabled after Repeat Injection by Temporary Coronary Occlusions in a Pig Model of Heart Failure

Renata Mazurek, Anjali J. Ravichandran, Spyros Mavropoulos, Tomoki Sakata, Kiyotake Ishikawa
Cardiovascular Research Institute, Icahn School of Medicine at Mount Sinai, New York, NY

Introduction: Cardiac gene therapy with adeno-associated virus (AAV) has been challenged by low efficacy in human trials. A significant barrier to intravascular delivery is the formation of neutralizing antibodies (NAbs), which may preclude repeat dosing. Using a pig model of heart failure, we previously showed that AAV transgene expression via intracoronary (IC) administration can be significantly enhanced by brief simultaneous coronary artery and coronary sinus occlusions (CAO + CSO delivery). We hypothesized that this technique could also overcome NAb inhibition. Methods: Yorkshire pigs (38.2±1.1 kg, n=9) pre-screened for low or negative NAbs against AAV6 were enrolled. Three groups (n=3/group) were designated to receive IC delivery of AAV6 encoding for luciferase (AAV6.Luc) one week after acute myocardial infarction (MI). One group received AAV6 (encoding for GFP, AAV6.GFP) 3-4 weeks prior to MI as a first injection in order to induce NAbs against AAV6. This group then received AAV6.Luc by CAO + CSO as a second AAV6 injection. The other groups (without prior AAV6 injection) received AAV6.Luc by CAO + CSO or by slow continuous delivery as reference. Luciferase assay was assessed for expression in heart regions one month later. NAb assay and ELISpot assay with detection of interferon (IFN)-γ were conducted to evaluate humoral and cellular immune responses pre- and post-AAV6.Luc injection. Results: In the delivery groups without previous AAV6 injection, CAO + CSO delivery resulted in significantly higher luciferase expression in all cardiac tissue regions (infarct, infarct-border, and remote posterior epi- and endocardial) compared to continuous delivery (>700-fold global difference). In the group that received previous AAV6.GFP injection, NAb assay reflected an increase in the NAb titer one month following AAV6.GFP (first) injection and prior to AAV6.Luc (second) injection. Even with the presence of induced NAbs, CAO + CSO delivery led to positive luciferase expression within infarct and infarct-border tissues (Figure). IFN-γ detection by ELISpot demonstrated increased number of spots after each AAV6 injection, with the highest detection one month after AAV6.Luc delivery, suggesting increased cellular immune response following second AAV6 injection. Conclusion: This study addresses the possibility of achieving AAV gene expression in the presence of neutralizing antibodies using a novel delivery technique, while also suggesting upregulation of cellular immunity after repeat dosing.

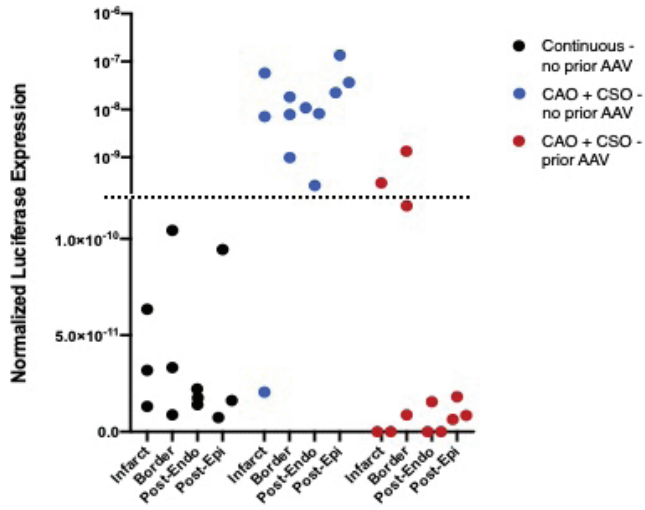


Figure. Luciferase expression in the heart by AAV immunity and delivery group. AAV6 encoding for luciferase was delivered by intracoronary injection one week post-MI to three groups (n=3/group): Continuous infusion without prior AAV6 injection (reference), delivery with coronary artery and coronary sinus occlusions and a cardiac support device (CAO + CSO) without prior AAV injection, and CAO + CSO with prior AAV injection (second dose). Negative values are represented as 0.0.

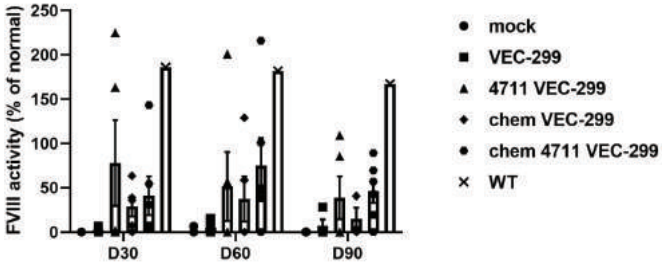
1266 Improved *In Vivo* Hemophilia A Gene Therapy Based on A Novel Immune-Escape Lentiviral Vector System

Jie Gong[1,2], Rui Yang[2], Yuchen Liu[3], Lung-Ji Chang[2,3]
[1]Chengdu Women's and Children's Central Hospital, Chengdu, China,[2]Medicine, University of Electronic Science and Technology of China, Chengdu, China,[3]Geno-immune Medical Institute, Shenzhen, China

Hemophilia A (HA) is an X-linked monogenic coagulation disorder in the intrinsic coagulation cascade resulting from deficiency of the factor VIII (FVIII, F8) gene. Gene therapy is a promising treatment for HA. However, a major limitation to direct intravenous (iv) lentiviral vector (LV) injection has been the poor biodistribution and fast clearance of the LV particles from the circulation by professional phagocytes and/or innate immune activation. We have developed an advanced LV system for intravenous (iv) F8 gene therapy based on a novel B domain deleted F8-BDD gene, with fully restored N-glycosylation sites (F8-299) in the B domain and an endothelial-specific (VEC) promoter which demonstrate increased coagulation function with reduced inhibitory effect (Gong et al. J Biol Chem 2021, DOI: 10.1016/j.jbc.2021.101397). To reduce immune clearance of the iv injected LVs, we used a dual immune-shield strategy for LV packaging referred to as "4711-LV-VEC-299", which is based on increased CD47 expression on the packaging cell surface to suppress phagocytosis of the assembled virus particles, and the incorporation of cytomegalovirus US11 and ICP47 in the packaging cells to induce degradation of major histocompatibility complex class I (MHC-I). LV iv injection was performed after a non-myeloablative conditioning (chem) approach with busulfan (3.2 mg/kg), cyclophosphamide (100 mg/kg) and dexamethasone (5 mg/kg) or

a non-conditioning approach. Day 0 refers to the day of LV iv injection of transduction unit of $8x10^7$/mouse. The vector copy number (VCN) in the blood of chemo-conditioned "chem VEC-299" and "chem 4711-VEC-299" groups reached 7% and 20% on day 7, respectively. It gradually reduced from day 15 to 60 to below 1%. Functional assay based on chromogenic assay using F8 mouse plasma at day 30, 60, and 90 after treatment demonstrated high F8 activity in groups "4711-VEC-299" and "chem 4711-VEC-299", approaching the therapeutic range (~50% of the normal range) from day 30 to 90, whereas the "VEC-299" and "chem VEC-299" mice showed low F8 activities (see Figure). The 4711-VEC-299 LV treatments without chemo-conditioning also showed F8 activity in plasma, indicating the success of immune escape of the "4711" LV. Further *in vitro* and *in vivo* characterization of the 4711 LV is underway to illustrate the mechanism of immune evasion. These early results demonstrated that iv 4711-LV-VEC-299 without chemo-conditioning in the F8 knockout mice was feasible and exhibited high and long-lasting coagulation function and immune evasion. The novel 4711-LV system could be a potentially safe, convenient and effective HA gene therapy tool in clinical applications.



1267 Formulation and Process Development for Stable Lyophilized AAV8 Drug Products

Yao Chen, Jonathan Wert, Nick Lai, Xiaoyan Wang, Shuai Li, Mohammed Shameem, Li Zhi, Dingjiang Liu
Regeneron Pharmaceuticals, Tarrytown, NY

Recombinant adeno-associated virus (rAAV) vectors have emerged as the leading gene delivery platform for treatment of monogenic disorders due to their superior safety profile, diverse tissue tropisms, and relatively mild immunogenicity. Currently for clinical and commercial products, rAAV vectors are typically formulated and stored at ≤-65°C as frozen liquid solutions. However, long-term storage of frozen liquid AAV products are often far from ideal because it may result in shorter drug product shelf-life compared to recombinant protein-based biologics, and also present challenges for supply chain and inventory management. Consequently, there is great interest in developing robust lyophilized AAV drug products that are stable at refrigerated condition (2-8°C). In this study, we systematically evaluated the key formulation excipients required for stable lyophilized AAV products including buffers, salts, cryoprotectants, surfactants, and bulking agents. We optimized the concentrations as well as the ratios between the key excipients. This led to the identification of the lead formulation that demonstrated short-term in-solution stability at 25°C and upon lyophilized, sufficient long-term stability at 2-8°C with the elegant cake appearance of the lyophilized drug product. Contrary to what was reported recently, we showed that by using a robust lyophilization process based on optimization of critical process parameters, we successfully promoted crystallization of mannitol and achieved an elegant product cake with low moisture content. Furthermore, our study demonstrated that mannitol has no detrimental effect on product quality and stability. The systemic approach we demonstrated in this study could be applied to streamline the development of lyophilized AAV gene therapy products with various target transgenes and capsid serotypes.

1268 A Novel Three-Plasmid Packaging System for High-Yield and rcAAV-Free rAAV Production

Mengyue Li[1], Chuangang Cheng[1], Chao Cheng[1], Leilei Xia[1], Yunhuan Wei[1], Jiachi Liu[1], Min Zhang[1], Yang Cao[1], Qiutang Li[2], Bose Kalampanayil[2], Su Xiao[1]
[1]Neurophth Biotechnology, Suzhou, China,[2]Neurophth Therapeutics, San Diego, CA

The HEK293-triple plasmid transfection platform is most widely used for rAAV clinical manufacturing. Despite countless advantages, the relatively low yield and generation of replication-competent AAV (rcAAV) particles impede its wider applications for future gene therapies. To overcome these bottlenecks, we designed a novel three-plasmid packaging system, Higher-Expression Recombinant AAV (HERA) system, which increased the rAAV yield by 5 to 10-fold and reduced rcAAV to an undetectable level. We implemented the following strategies to improve rAAV upstream yield: (1) screening and reconstitution of promoters for rep and cap gene; (2) selection and insertion of heterologous intron DNA sequences; (3) nucleic acid point-mutation to regulate pre-mRNA splicing; (4) optimization of rep/cap expression stoichiometry. To eliminate rcAAV, the following strategies were evaluated: (1) Homology reduction to prevent recombination events; (2) Stuffer insertion to prevent co-packaging; (3) recombination element separation; (4) transfection reagent compatibility screening. The HERA system has been evaluated in Neurophth's suspension HEK293 platform for multiple preclinical and clinical batches, across different serotypes and genes of interest. Herein, we present process and quality attributes summaries of historical batches to demonstrate the HERA system not only significantly reduced manufacturing scale but also achieved an improved quality profile. Utilizing the HERA system, the upstream rAAV yields were enhanced across various projects to the range of 3E14 vg/L to 1E15 vg/L, while the upstream rAAV yields were in the range of 3E13 vg/L to 2E14 vg/L when using the traditional plasmid packaging approach. Consequently, the HERA system has the potential to drastically reduce the demand for manufacturing scale and production cost due to the 5 to 10-fold improvement in rAAV yield. Meanwhile, the HERA system produced rcAAV-free drug products with comparable purity and impurities profiles to drug products produced using the classical plasmid packaging system.

1269 A Highly Sensitive NanoLuciferase Reporter Enables Efficient Functional and Genetic Biodistribution Assessment of AAV in Mice

Morten Seirup, Kirsten Wingate, Kara B. Machleidt, Douglas Horejsh, Trish Hoang, Marjeta Urh
Promega Corporation, Fitchburg, WI

AAV based gene therapy is a rapidly growing field and has the potential to cure a wide variety of monogenic diseases by delivering replacement for genes harboring undesirable mutations. To maximize efficacy and safety of the treatment, the delivery of the replacement genes must target specific tissues. Unfortunately, naturally occurring AAV serotypes display broad tissue tropism. Engineering of AAV capsids has been a favorable approach to enhance specificity toward target tissues while minimizing off-target delivery. AAV variant selection often comprise of large sample sets and a complex workflow that requires automation. Each animal is injected with a variant AAV capsid library, followed by the isolation, purification and sequencing of DNA from each AAV infected tissue. Herein we report a simple, fast and automated workflow to enable extraction, purification and quantification of viral DNA from tissue samples in a high throughput fashion. To demonstrate our workflow, we generated AAV9 viruses expressing a NanoLuc® reporter (AA9-NanoLuc) to examine tissue tropism in animals via bioluminescent live imaging. The NanoLuc® reporter displays superior brightness enabling detection at day 7 post injection. Additionally, it is small enough to be packaged into both single stranded and self-complementary AAV systems. In our study, we divided 40 mice into 4 groups of 10 (5 males and 5 females) and injected varying amounts of AAV9-NanoLuc into each group (Negative - 0 GC/Kg, Low - 1e10 GC/Kg, Medium - 1e11 GC/Kg, High - 1e12 GC/Kg). Two weeks after injection, bright and dose dependent bioluminescent images were captured via live whole-body imaging. Next, tissues were collected, and total DNA was extracted and purified using the Maxwell nucleic acid extraction system. Total DNA quantity and purity were assessed, followed by determination of AAV viral titers by normalization to house-keeping gene *TERT* using digital droplet PCR. We found AAV titers of several organs correlated with their luminescent signals. The viral titers accumulated in targeted tissues were also strongly dependent on the injection dose. In summary, we report a versatile NanoLuc® reporter that is bright and well suited to examine tissue tropism in live animals. In addition, we provide a simple, single day workflow which enables high throughput compatible viral titer determination of AAV infected tissues. The combination of our reporter and our proposed workflow would advance efficiency and effectiveness when screening AAV capsid libraries.

1270 The Optimization of AAV9 Dosage and Fluorescein Concentration in Direct Vagus Nerve Injection to Treat Autonomic Dysfunction

Nanda L. Regmi[1], Diane Armao[2], Xin Chen[1], Yuhui Hu[1], Rachel M. Bailey[1], Steven J. Gray[1]
[1]Department of Pediatrics, UT Southwestern Medical Center, Dallas, TX,[2]Department of Radiology, University of North Carolina, Chapel Hill, NC

We previously reported that a direct vagus nerve injection of AAV9/GAN (scAAV9/JeT-GAN) in combination with lumbar intrathecal (IT) delivery added benefit to the treatment of autonomic dysfunction caused by giant axonal neuropathy (GAN) (ASGCT-2020, Abstract#936). In that study, a single dose of 2.6E12 vg/rat IT simultaneously combined with a dose of 6.5E11 vg/rat directly into the vagus nerve was conducted in GAN-KI (knock-in) adult rats. The AAV9/GAN vector injected into the vagus nerve was mixed with luxol fast blue (LFB) dye to enable visualization and monitor the injection. In the present study, our goal was to identify the optimal dosage to transduce critical regions of the autonomic nervous system by injecting AAV9/GFP (scAAV9/CBh-GFP) into the vagal nerve of wild type adult Fischer 344 rats. To achieve this goal, we mixed five different doses (6.5E11, 2.5E11, 7.6E10, 2.5E10, or 2.5E9 vg/rat) of AAV9/GFP with 1% LFB, dosed each rat with a single unilateral injection of AAV9/GFP into the left vagus nerve at cervical region, and harvested autonomic gangaila along the vagus nerve and medulla for immunohistochemistry analyses 28 days post administration. We observed a dose dependent transduction variation in nodose ganglia of vagus nerve, dorsal motor nucleus, solitary tract and nucleus, and nucleus ambiguous of caudal medulla. The two highest doses (6.5E11 and 2.5E11 vg/rat) resulted in abundant and equivalent transduction efficiency in the cervical vagus nerve, nodose ganglia and brainstem sites of caudal medulla, leading us to conclude 2.5E11 vg/rat as the minimal dosage required to achieve maximal transduction efficiency of these critical regions of autonomic nervous system. Considering that LFB cannot be used as a tracking dye in humans to our knowledge, we further evaluated a range of fluorescein concentrations for their impact on transduction and feasibility to enable tracking of the injection fidelity in real time. Using a constant dose of 2.5E11 vg/rat AAV9/GFP, mixed with four different fluorescein concentrations (0.001, 0.002, 0.004, and 0.008) prior to vagal nerve injection into wild type Fischer 344 rats, we identified 0.004% fluorescein as the most optimal concentration to monitor injection fidelity. Taken together, these studies have identified practical parameters for optimal injection of AAV9 directly into the vagus nerve to target critical regions of the autonomic nervous system, which are prerequisite to facilitate the translation of this approach to larger animals and humans.

1271 Combining CAR T Cell Therapy with Novel STING Agonist for Successful Treatment of Solid Tumors

Ugur Uslu[1,2], Amanda V. Finck[1,2], Sofia Castelli[1,2], Tong Da[1,2], Charles-Antoine Assenmacher[3], Lijun Sun[4], Regina M. Young[1,2], Zhijian J. Chen[5,6,7], Carl H. June[1,2]

[1]University of Pennsylvania, Philadelphia, PA,[2]Parker Institute for Cancer Immunotherapy at University of Pennsylvania, Philadelphia, PA,[3]University of Pennsylvania, School of Veterinary Medicine, Philadelphia, PA,[4]ImmuneSensor Therapeutics, Dallas, TX,[5]University of Texas Southwestern Medical Center, Dallas, TX,[6]Center for Inflammatory Research at University of Texas Southwestern Medical Center, Dallas, TX,[7]Howard Hughes Medical Institute, Chevy Chase, MD

While chimeric antigen receptor T cells (CART) have achieved therapeutic success in hematological malignancies, similar results have not been observed in patients with solid tumors to date. Hurdles in CART therapy targeting solid tumors include insufficient cell trafficking into the tumor, as well as the immunosuppressive tumor microenvironment (TME) which hampers engineered T cell function. A possible strategy to increase efficacy and therapeutic response of CART in solid tumors could be the combined use with IMSA101, a novel stimulator of interferon genes (STING) agonist, to effectively modify the tumor microenvironment prior to engineered T cell administration. To test this approach, we established two syngeneic flank tumor models using immunocompetent C57BL/6 mice. Mice were either implanted with PDA7940b, an immunologically cold murine pancreatic ductal adenocarcinoma (PDA) cell line derived from KPC ($Kras^{LSL.G12D/+}p53^{R172H/+}$) mice, or with B16, an immunogenic murine melanoma cell line. Approximately one week after tumor cell injection, animals were treated with intratumoral IMSA101 alone, intravenous CART alone, IMSA101+CART, or were left untreated for control. At the time point of peak CART expansion, the TME was analyzed by flow cytometry of tumor single cell suspension in addition to pathological assessment and immunohistochemistry (IHC) of bulk tumor tissue. RNA was extracted from intratumoral CART for gene expression and pathway enrichment analyses, and mouse serum was analyzed for cytokines. In addition, a xenograft flank tumor model was established using NOD/scid/IL2r$\gamma^{-/-}$ (NSG) mice and human PDA AsPC-1 cells to characterize the effects of IMSA101 on human CART. Tumor clearance was seen in all B16 tumor-bearing mice, as well as in some PDA7940b tumor-bearing mice when both treatments were combined. This resulted in significantly improved overall survival when compared to mice treated with CART alone or IMSA101 alone in both syngeneic models. Treatment-related weight loss or clinical signs of distress were not observed in any of the mice. More CART were detected in tumors of IMSA101+CART-treated mice when compared to mice treated with CART alone. Importantly, gene expression analysis of intratumoral CART between these two cohorts showed activation as well as effector T cell signatures in CART+IMSA101-treated mice. In addition, more pro-inflammatory cytokines were detected in serum of mice receiving combination treatment in both syngeneic models. IMSA101 also enhanced human CART anti-tumor efficacy, resulting in significantly improved overall survival of NSG mice. Further analyses in xenograft tumor models are currently ongoing. In summary, intratumoral administration of IMSA101 improved CART trafficking into the tumor, induced intratumoral CART activation, and significantly enhanced overall anti-tumor efficacy and overall survival in two syngeneic flank tumor models and in an immunodeficient model with human CART, suggesting direct and indirect mechanisms of enhanced antitumor immunity. These promising results paved the way for development of the combination approach into the clinic.

1272 Comparison of CAR-T Cell-Mediated Cytotoxicity Assays with Suspension Tumor Cells Using High-Throughput Plate-Based Image Cytometry Method

Yu-Jun Sun[1], Yi-Chun Chen[1], Wei-Kai Hua[1], Sareina Wu[1], Bo Lin[2], Leo Li-Ying Chan[2]

[1]GenomeFrontier Therapeutics, Taipei, Taiwan,[2]Nexcelom Bioscience, Lawrence, MA

In the recent decade, chimeric antigen receptor (CAR)-T cell therapy has revolutionized strategies for cancer treatments due to its effective clinical efficacy and response for B cell malignancies. Currently, there are six CAR-T cell products available in the market including Kymriah®, Yescarta®, Tecartus®, Breyanzi®, Abecma®, and Carvykt™. The success of CAR-T cell therapy has stimulated the increase in the research and development of various CAR constructs to target different tumor types. Therefore, a robust and efficient in vitro potency assay may be beneficial to quickly identify potential CAR gene design from a library of construct candidates. Traditionally, in vitro CAR-T cell-mediated cytotoxicity is assessed using release assays such as 51Cr (radioactivity), calcein (fluorescence), and LDH (enzymatic). Image cytometry methodologies have been utilized for various CAR-T cell-mediated cytotoxicity assays using different fluorescent labeling methods, mainly due to their ease-of-use, ability to capture cell images for verification, and higher throughput performance. In this work, we employed the Celigo high-throughput plate-based Image Cytometer to evaluate and compare two CAR-T cell-mediated cytotoxicity assays using GFP-expressing or fluorescent dye-labeled myeloma and plasmacytoma cells. In regards to the performing time and E:T ratio-dependent CAR-T cell-mediated cytotoxicity assays, the GFP-based method demonstrated higher sensitivity in detecting the level of cytotoxicity when compared to the CMFDA/DAPI viability method. We have established the criteria and considerations for the selection of cytotoxicity assays that are fit-for-purpose and to provide meaningful results for the specific testing conditions. * All trademarks, service marks, trade names, and brand names are the property of their respective owners.

1273 Addressing Key Challenges to Enable Global Access to Gene Therapies

Markus J. Haindl

Global Head Gene Therapy Technical Development, Roche, Penzberg, Germany

Gene Therapies are currently where Monoclonal Antibodies were 25 years ago and we need a shift of technical development and analytical characterization paradigms as well as transformative innovation for reliable supply, more sustainable cost of manufacturing as well as enhanced molecular understanding of these next generation therapeutics. This presentation provides insights to our approaches

and scientific advancements to transform manufacturing and improve molecular understanding by analytical characterization in order to enable global access to AAV based therapeutics.

1274 Optimization of Transfection Reagent Formulation and Experimental Conditions to Maximize the Percentage of Full Adeno-Associated Virus Capsids

James J. Ludtke[1], Oksana Hart[1], Nicolas Rossi[1], Yuyuan Wang[1], Anatoly Pinchuk[1], Laura Juckem[2]

[1]Mirus Bio LLC, Madison, WI,[2]Mirus Bio, Madison, WI

Adeno-associated virus (AAV) has emerged as a leading platform for gene delivery for the treatment of a variety of human diseases. Generating high titer AAV at large-scale is technically challenging; however, process optimization (improved vectors, cells, media, culture conditions and transfection reagents) has resulted in robust improvements in AAV yield. Increasing the total yield of AAV manufactured is critical to moving gene therapies into mainstream medicine. Historically, viral genomes measured by qPCR or dPCR was paramount; however, the importance of the quality of the AAV, including the percentage of capsids containing AAV genomes as measured by the percentage if full capsids, is now considered a critical quality attribute (CQA) in generating therapeutic AAV. In response to this need, Mirus Bio is developing a new transfection formulation that provides multi-fold increases AAV genome titers over existing PEI based reagents while also increasing the percentage of full capsids. During these studies, using AAV8 as a model system, we have found that the transfection reagent used to generate recombinant AAV preparations in suspension 293 cells has a strong effect on not only the genome titer, but also on the virus quality as measured by the percentage of full capsids. Other factors affecting the percentage of full capsids were assessed with top candidates. These included: cell density, complex formation time, DNA dose (µg pDNA per ml of culture), and transfection reagent-to-DNA ratio. When using a high performing transfection formulation, alterations in transfection and/or cell growth conditions can have a larger effect on the percentage of full capsids compared to genome titer. The data presented in this poster illustrates how changes in the upstream transfection process can affect the AAV8 titer, and/or the quality of the virus produced which can positively affect downstream processing.

1275 Large-Scale Production of High-Quality Recombinant Adeno-Associated Virus Using Short-Term Zonal Ultracentrifugation

Mikako Wada[1], Naoya Uchida[1,2], Guillermo Posadas-Herrera[1], Hiromi Hayashita-Kinoh[1], Yuji Tsunekawa[1], Yukihiko Hirai[1], Takashi Okada[3]

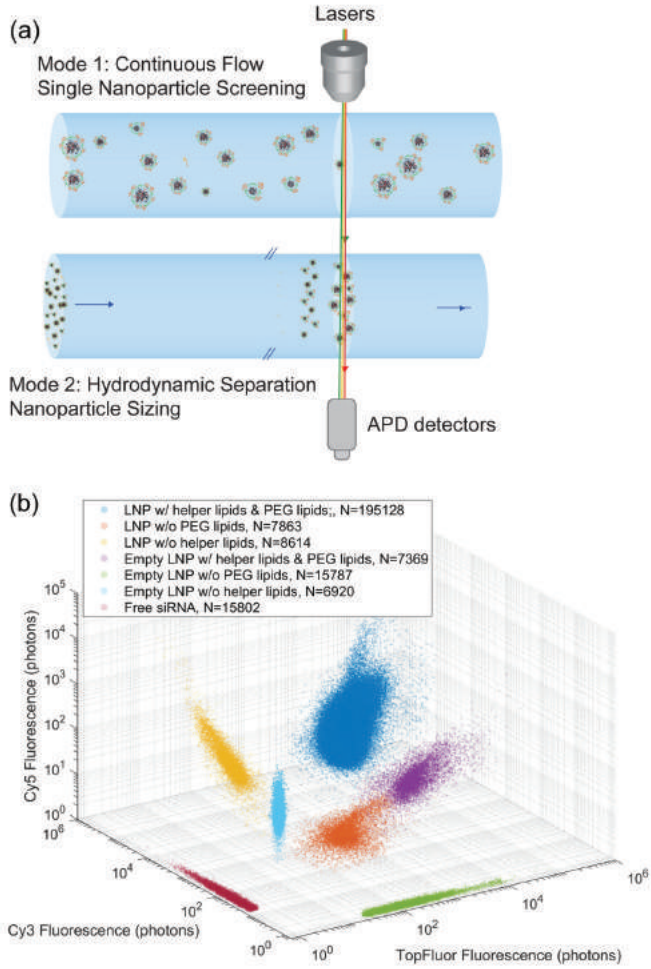
[1]Division of Molecular and Medical Genetics, Center for Gene and Cell Therapy, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan,[2]National Institutes of Health, Bethesda, MD,[3]Division of Molecular and Medical Genetics, Center for Gene and Cell Therapy, The Institute of Medical Science, The University of Tokyo, Minato-city, Tokyo, Japan

Background: Purification of recombinant adeno-associated virus (rAAV) is required for the safe and efficient transduction in rAAV-based in vivo gene therapies, because rAAV products contain full-genome (functional), intermediate, and empty rAAV particles as well as host-cell proteins. However, the current standard method for rAAV purification at the laboratory scale (up to 180mL) is based on two-day ultracentrifugation with a cesium chloride (CsCl) density-gradient protocol, limiting large-scale purification of functional rAAV for clinical usage. In addition, the infectivity decreases when the rAAV is incubated in CsCl over time. Therefore, in this study, we sought to develop a short-term purification method for large-scale rAAV production at high purity by using a zonal ultracentrifuge. Methods: rAAV9 encoding ZsGreen1 was collected from culture supernatant (without cell lysis) 5 days after plasmid transfection. Large-volume rAAV-containing culture media (up to 1,000mL) and escalating densities (2 or 4 steps) of CsCl solutions were separately placed in the zonal rotor, respectively. Following large-scale density-gradient ultracentrifugation of rAAV, the samples were fractionated automatically. These samples were evaluated by rAAV genome copies in quantitative PCR, rAAV capsid protein amounts in western blotting, and ZsGreen1 transduction efficiency in flow cytometry. The purity of rAAV was analyzed by analytical ultracentrifuge (AUC) and transmission electron microscope (TEM) with phosphotungstic acid stain. The genomic DNA regions packaged in rAAV particles were detected by droplet digital PCR (ddPCR) using various primers and probes targeting the whole vector genome. Results: We performed 2-step CsCl density-gradient ultracentrifugation with a zonal rotor, allowing for a large volume (900-1000mL) of rAAV purification as well as shorter ultracentrifugation for 4-5 hours with a steeper density-gradient in the area of rAAV fractions, as compared to our control method of 4-step density-gradient (300mL) for 10 hours. rAAV capsid proteins were detected in 2 of the fractions, one of which also contained the peaks of rAAV capsid, genome copies, and ZsGreen1 transduction, demonstrating a separation between functional full-genome and non-functional empty rAAV particles. The intermediate particles would be included between these fractions. We detected a single AUC peak with separate sedimentation coefficients for fractions of full-genome (about 90S) and empty (about 60S) vectors, demonstrating a high-purity separation of rAAV. Interestingly, the whole genome regions were detected at similar levels in full-genome rAAV by ddPCR; however, ITR signals were 2.5-2.9 fold higher than the ZsGreen1 signal in the empty particles, suggesting that ITR fragments can be packaged in 'empty' particles. In addition, we purified large-volume rAAV after removing small molecules and increasing concentration by simple pretreatment (up to 1.13x1014 v.g.). Conclusion: We developed a 2-step density-gradient ultracentrifugation method with a zonal rotor in 4-5 hours, allowing for large-scale purification of functional full-genome rAAV. We also improved the fractionation system for short-term purification. Our large-scale rAAV purification method would be applicable for considerable in vivo experimentation and clinical investigation.

1276 Uncovering Nucleic Acid Payload and Size of Lipid Nanoparticles via A High-Throughput Single Nanoparticle Analyzer

Sixuan Li, Yizong Hu, Jinghan Lin, Zachary Schneiderman, Kuangwen Hsieh, Lai Wei, Fangchi Shao, Efrosini Kokkoli, Hai-Quan Mao, Tza-Huei Wang
Johns Hopkins University, Baltimore, MD

Introduction: Lipid nanoparticles (LNPs) have broad applications as vehicles for RNA vaccines and therapeutics. However, the fundamental understanding of the structure-property-function relationships of the LNP system falls behind technological advancement and could hamper further development in more critical settings. In particular, there is limited understanding of the formation of subpopulations during manufacturing, single-nanoparticle nucleic acid and lipid payload level, or the correlation between nanoparticle payload and size. Here, we assessed the siRNA payload and content loading and distribution of two lipid components in a benchmark siRNA LNP formulation and the size of LNPs at the single-nanoparticle level. These results could provide more insights into the LNP assembly mechanism. **Methods**: We used Cylindrical Illumination Confocal Spectroscopy (CICS), a technique recently applied for LNP characterization[1] to examine the LNPs with fluorescent-labeled Cy3-siRNA, TopFluor-PC lipids, and Cy5-PEG lipids (Fig. 1a). The LNPs were injected continuously or in sample plug for Single Molecule Free Solution Hydrodynamic Separation (SML-FSHS)[2] in a microfluidic channel (Fig. 1a). A commonly referenced benchmark formulation was studied with the dosage of ionizable lipid DLin-MC3-DMA, cholesterol, the helper lipid DSPC, and DMG-PEG2000 at a molar ratio of 50:38.5:10:1.5. The LNPs were formulated by rapid mixing in a T-junction at pH 4.0 (acetate buffer) and dialyzed against PBS at pH 7.4. **Results**: The 3-color labeled siRNA LNPs were screened at the single nanoparticle level by CICS, and their signals were analyzed based on the fluorescence coincidence criteria. The fluorescence of all the identified events (>250,000 particles) was plotted in 3D space (Fig. 1b). 80.7% of the LNP signals were siRNA LNPs with both helper lipids and PEG lipids; 3.3% were siRNA LNPs without PEG lipids; 3.6% were siRNA LNPs without PC helper lipids; 3.0% were empty LNPs with both helper lipid and PEG lipid; 6.5% were empty LNPs without PEG lipids; 2.9% were empty LNPs without PC helper lipids. There was a total of 12.4% empty LNPs. CICS reported an average of 29.0 siRNAs per LNP for this formulation. Next, SML-FSHS was applied to analyze the hydrodynamic size of the siRNA LNPs at three PEG lipid concentrations (4.5%, 1.5%, 0.5% PEG). SML-FSHS yielded larger particle sizes (59 nm, 87 nm, and 115 nm at peak) compared to CryoTEM (28 nm, 41 nm, and 60 nm at peak) for LNPs at 4.5%, 1.5%, 0.5% PEG, respectively, as SML-FSHS measures the hydrodynamic size including the corona of the LNPs, whereas CryoTEM reveals the size of LNP cores.



Conclusions: This CICS-based LNP composition analysis technique allows for quantitative assessment of siRNA LNP subpopulations such as empty LNP percentage, lipid distribution, and siRNA payload and distributions. It also measures the hydrodynamic size of LNPs, incorporating the hydrodynamic separation. Overall, the method offers a powerful single nanoparticle analysis tool to study the structure-property-function relationships of LNPs. **Reference**: [1] *Nat. Commun.* **2022**, *13* (1), 5561. [2] *J. Am. Chem. Soc.* **1016**, *138* (1), 319-327.

1277 Development of Rationally Designed CAG-Based Promoters for Use in Gene Therapy

Dustin Lee, Josefa M. Sullivan, Natalia Fabela, Edgar Hernandez, Matthew J. During, Alexandria Forbes, Ce Feng Liu
Molecular & Protein Engineering, MeiraGTx LLC, New York, NY

Background: The promoter is an essential cis-regulatory element in any DNA-based gene therapy. It directly controls gene transcription and thereby therapeutic protein expression. In the context of genetic medicines, stronger promoter activity may enable a lower vector dosage of the given gene to achieve therapeutic effect, reducing safety risks associated with high vector dosages, as well as reducing

manufacturing costs. To date, an overwhelming majority of promoters used in gene therapy clinical trials are based on cellular CAG or viral CMV promoters. We endeavored to engineer new CAG-based promoters with the aim to increase potency and reduce size to create an improved set of strong, durable constitutive promoters amenable to gene therapy applications. **Methods:** The CAG promoter is a synthetic hybrid promoter consisting of the CMV immediate early enhancer and the promoter, the first exon, and a modified first intron of the chicken beta actin gene. We rationally designed a series of 82 new CAG promoter variants by systematically introducing modifications to each of the promoter elements and tested them in different *in vitro* and *in vivo* models. **Results:** In our library of CAG promoter variants, 51 are smaller than the original CAG, of which 22 are fewer than 1000 base pairs in length. In HEK293T cells, 67 CAG promoter variants were found to be stronger than the original CAG with the strongest promoter exhibiting 13-fold improvement in potency. Two CAG promoter variants, based on improved *in vitro* activity and smaller size (~40% size reduction), were administered by tail vein injection into C57BL/6 mice. Expression in the liver improved by up to 4-fold compared to the original CAG promoter. **Conclusions:** Through our promoter engineering platform, we successfully created a library of promoters based on CAG, a proven effective and safe promoter, with increased potency at driving gene expression and that displays promise for the next generation of gene therapy development.

1278 Utility of Cryofluorescence Tomography (CFT) as an Unbiased Method to Describe AAV Biodistribution

Samantha A. Yost[1], Justin D. Glenn[1], Hayley B. Carroll[1], Steven Foltz[1], April R. Giles[1], Elad Firnberg[1], Sungyeon Cho[1], Trang Nguyen[1], William M. Henry[1], Karolina J. Janczura[1], Joseph T. Bruder[1], Ye Liu[1], Olivier F. Danos[1], Subha Karumuthil-Melethil[1], Sanjana Pannem[2], Valerie Yost[2], Yelena Engelson[2], Hemi Dimant[2], Andrew C. Mercer[1], Jared B. Smith[1]

[1]Regenxbio, Inc., Rockville, MD,[2]Invicro, Boston, MA

The use of adeno-associated viruses (AAV) as gene delivery vectors has vast potential for the treatment of many severe human diseases. A small group of intensively studied AAV capsids have been propelled into pre-clinical and clinical use, and more recently, marketed products; however, many less-studied, naturally occurring capsids may also have desirable properties (e.g. potency differences, tissue tropism, reduced immunogenicity, etc.) that have yet to be thoroughly described. Within this under-studied group of capsids is AAV7, a potentially therapeutic capsid for which tropism studies are limited, and direct, head-to-head comparisons with well-described capsids have not been performed. We sought to characterize the biodistribution of this capsid more fully by several methods including quantitative PCR, immunofluorescence (IF) and immunohistochemistry (IHC), and whole-body imaging via cryofluorescence tomography (CFT) as an unbiased method to look for novel regions of transduction. CFT of whole mice was performed three weeks after IV administration of AAV7 or AAV9 carrying an EGFP transgene driven by CAG, or co-administration of AAV7-EGFP and AAV9-tdTomato. This was compared to traditional biodistribution analysis of vector genome copies and expressed RNA transcripts. Superiority of AAV9 in mouse skeletal muscle was shown over AAV7 and was confirmed via CFT and IF. Cardiac transduction by AAV7 trended higher than AAV9 in all studies. AAV7 and AAV9 both transduce the mouse brain with equal efficiency according to PCR-based biodistribution data; however, by CFT and IHC, cell type differences were found within the brain, with AAV7 being localized mostly around blood vessels within the brain, and AAV9 widely transducing astrocytes and neurons. A surprising finding from CFT was the presence of fluorescence in facial structures, some of it highly concentrated, for both AAV7 and AAV9. As this is not typically an area sampled by traditional biodistribution methods, this finding has been largely overlooked. In particular, the mandible showed the highest intensity of EGFP fluorescence of any other tissue for both AAV7 and AAV9. The incisor also had measurable EGFP fluorescence. As the mouse mandible is surrounded by muscle tissue that likely was transduced, we conducted an IHC study to further ascertain detailed information about the transduction seen in and around mouse facial structures and investigate tropism differences between AAV7 and AAV9. Surprisingly, strong transgene expression was observed throughout the head, as verified by IHC, including regions of the cranial sinuses, teeth, and mandible for both AAV7 and AAV9, an attribute that has not been previously evaluated via traditional biodistribution methods. These data will help build a broader structure-function knowledge base in the field, present capsid engineering opportunities, and enable the use of novel capsids with unique properties. Overall, CFT represents an unbiased method to evaluate novel AAV capsids, eliminating initial bias in tissue sampling and giving precedent for further investigation of tissues of interest.

1279 Evaluating Pharmacology and Efficacy of Delandistrogene Moxeparvovec in Young and Aged DMD^{MDX} Rats

Rachael Potter, Chris Wier, Grace Cooper-Olson, Esther Wheeler, Emily Anderbery, Amber Kempton, Leah Clements, Kaitlin Adegboye, Alex Haile, Ellyn Peterson, Louise Rodino-Klapac

Sarepta Therapeutics, Cambridge, MA

Gene transfer therapy is a promising treatment for patients with Duchenne muscular dystrophy (DMD). Delandistrogene moxeparvovec (previously known as SRP-9001) is an investigational recombinant adeno-associated viral vector-based gene transfer therapy designed to compensate for missing dystrophin in DMD by delivering the SRP-9001 dystrophin transgene, which encodes a shortened, engineered dystrophin protein that retains key functional domains of the wild-type protein. The purpose of this preclinical study was to evaluate the myocardial efficacy and safety of intended commercial process delandistrogene moxeparvovec material in DMD^{MDX} rats. DMD^{MDX} rats are a valuable alternative DMD animal model, as they demonstrate cardiac dysfunction that recapitulates cardiac dysfunction of patients with DMD. We performed systemic, intravenous delivery of intended commercial process delandistrogene moxeparvovec material in young (21-35 days old) and aged (3-5 months old) DMD^{MDX} rats. The older rats demonstrate a more severe phenotype in terms of fibrosis or cardiac disease progression. Rats received a dose of $1.33x10^{14}$ vg/kg. Ambulation activity was recorded via the Photobeam Activity System Open Field. Echocardiograms and histological analysis of fibrosis were used to evaluate cardiac disease.

Data from 12 weeks and 24 weeks post-systemic delivery demonstrated no evidence of cardiac toxicity. Importantly, there were no deaths attributed to treatment. Compared with the saline control, intended commercial process delandistrogene moxeparvovec material increased ambulation and vertical activity in young DMD^{MDX} rats and improved cardiac function. Protein expression was broadly distributed across skeletal muscle, the diaphragm, and the heart. Taken together, these findings confirm expression in cardiac muscle, as expected, and support the myocardial efficacy and safety of delandistrogene moxeparvovec. Further evaluation of cardiac disease phenotypes at 12 and 24 weeks post-systemic delivery utilizing several indicators of cardiac function will also be presented. This study was funded by Sarepta Therapeutics.

1280 P2Y12 is a Novel Druggable Target for Blocking Macrophage Myofibroblast Transition Driven Cancer Associated Fibroblast Formation in Lung Carcinoma

Kam Kwan Chan, Philip Chiu-Tsun Tang, Jeff Yat-Fai Chung

The Chinese University of Hong Kong, Hong Kong, Hong Kong

Macrophage-Myofibroblast Transition (MMT) is a newly discovered Smad3-dependent mechanism for the direct generation of protumoral cancer-associated fibroblasts (CAF) from tumor-associated macrophages (TAM). Better understanding of its regulatory mechanism would uncover novel therapeutic targets for developing precision medicine against CAF-driven non-small-cell lung carcinoma (NSCLC). By conducting high-resolution single-cell RNA-sequencing with bone marrow-derived macrophages (BMDM), we identified P2Y12 as a novel Smad3 direct target gene in the cells undergoing TGF-β-driven MMT *in vitro*. We found that macrophage P2Y12 level significantly correlated to the CAF abundance and associated with poorer overall survival of NSCLC patients. Genetic silencing of macrophage P2Y12 markedly suppressed MMT-driven myofibroblast formation and protumoral effectors *in vitro* and *in vivo*. Encouragingly, pharmaceutical inhibition of P2Y12 with FDA-approved P2Y12 inhibitor Clopidogrel effectively blocked MMT-driven CAF formation and cancer progression in mice bearing syngeneic lung carcinoma LLC as well as human NSCLC xenograft *in vivo*. Thus, we successfully identified macrophage P2Y12 as a druggable target for precisely targeting MMT-driven protumoral CAF formation in lung carcinoma.

1281 Improved Transgene Expression from GenY AAV Serotype Vectors in Human Cells *In Vitro* and in Murine Hepatocytes *In Vivo*

Aneesha Nath[1], Jakob Shoti[2], Geoffrey D. Keeler[2], Keyun Qing[2], Arun Srivastava[1]

[1]University of Florida College of Medicine, Gainesville, FL,[2]University of Florida, Gainesville, FL

We have previously reported that the distal 10-nts in the AAV2 D-sequence share partial homology with the glucocorticoid response element (GRE) ½ binding site, and that the AAV2 genomes in which the distal 10-nts with were replaced with the 15-nts consensus full-length GRE site mediated up to ~6-fold increased transgene expression in primary human skeletal muscle cells when packaged into AAVrh74 vectors (*Mol. Ther.*, 30: 237-238, 2022). In the current study, we examined whether similar increased efficacy of transgene expression could also be achieved with other AAV serotype vectors. To this end, HeLa cells were transduced with WT and GenY AAV2 vectors, and transgene expression was evaluated 72 hrs post-transduction. As can be seen in **Figure 1A**, The extent of transgene expression was ~2-fold higher with GenY AAV2 vectors, it was further increase by ~2-fold following dexamethasone-treatment, suggesting that the observed increase in transgene expression is indeed due to activation of the GR pathway, and that the GRE ½ site is potent enough to increase the transduction efficiency in response to dexamethasone-treatment. Transduction efficiencies of WT and GenY AAV2 vectors were also evaluated in C57BL6/J mice following intravenous delivery *in vivo*. These results, shown in **Figure 1B**, also document ~3-fold increase in transgene expression from GenY AAV2 vectors. Interestingly, sequence alignment of D-sequences of AAV1 through AAV6 revealed the absence of the GRE ½ site in the rest of the AAV serotypes (**Figure 1C**). The 15-nts consensus full-length GRE site was inserted in the AAV6 D-sequence to generate GenY AAV6 vectors. As can be seen in **Figure 1D**, GenY AAV6 vectors also mediated up to ~3-fold increase in transgene expression in HeLa cells compared with the WT AAV6 vectors, and it further increased by ~3-fold following dexamethasone-treatment. Since glucocor-ticoids, such as predni-solone, are routinely used prophylactically to mitigate the AAV vector-mediated host immune responses in clinical trials, our data suggest that insertion of the full-length GRE site in the recombinant AAV genomes may be a simple strategy to achieve increased trans-gene expression at lower doses of AAV vectors.

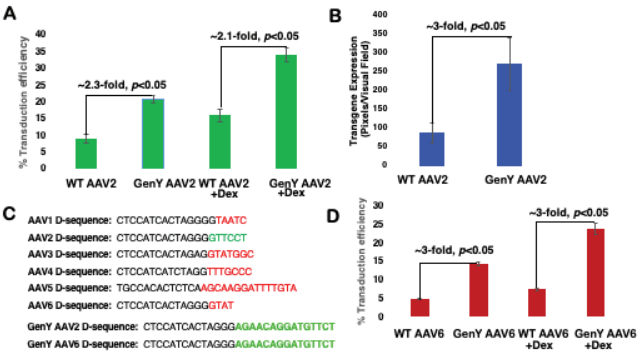


Figure 1: A. Transduction efficiency of WT and GenY AAV2 vectors in HeLa cells. Cells were transduced in triplicates at 500 vgs/cell of each vector, with or without pre-treatment of cells with 10 μM dexamethasone, and transgene expression was quantitated by flow cytometry. **B.** WT and GenY AAV2 vectors were injected intravenously at $1x10^{11}$ vgs/mouse (n=6 each) and transgene expression in liver sections was visualized under a fluorescence microscope 4-weeks post-injections. **C.** Sequence alignment of D-sequences in AAV1 through AAV6 serotypes. The GRE ½ site (green font) is present only in AAV2 D-sequence. 15-nts consensus full-length GRE site (bold green font) was inserted in AAV2 and AAV6 D-sequences to generate GenY AAV2 and GenY AAV6 vectors. **D.** Transduction efficiency of WT and GenY AAV6 vectors in HeLa cells. Cells were transduced in triplicates at 3,000 vgs/cell of each vector, with or without pre-treatment of cells with dexamethasone, and transgene expression was quantitated as described above.

1282 CRISPR Base Editing Approach to Treat Duchenne Muscular Dystrophy by Skipping DMD Exon 45

Devyani Swami[1], Michael Gapinske[1], Jackson S. Winter[1], Lauren Gapinske[1,2], Wendy S. Woods[1], Shraddha Shirguppe[1], Angelo Miskalis[1], Anna Busza[1], Dana Joulani[1], Colin Kao[1], Kurt A Kostan[3], Rashid bashir[1,2], Pablo Perez-Pinera[1,2]

[1]Bioengineering, University of Illinois at Urbana-Champaign, Urbana, IL,[2]Nick J. Holonyak Micro and Nano Technology Laboratory, University of Illinois Urbana Champaign, Urbana, IL,[3]bioengineering, University of Illinois, Urbana Champaign, Urbana, IL

Duchenne Muscular Dystrophy is an X-linked degenerative muscular disease that first manifests as muscle weakness and that progresses rapidly leading to paralysis and, ultimately, death of the patients in their 3rd decade of life. At the molecular level, Duchenne is caused by mutations in dystrophin, a protein that is critical for maintaining the stability of the muscle membrane by linking the cytoskeleton of the muscle cells with the extracellular matrix. While there is no cure for Duchenne, exon skipping with antisense oligonucleotides (AONs) has emerged as a highly promising therapeutic approach that interferes with the spliceosome to exclude exons containing mutations from mature mRNA, which creates a truncated dystrophin that ameliorates the symptoms of Duchenne. Currently, most methods of exon skipping require direct delivery of exon skipping oligonucleotides to the muscle cells, an approach that has several limitations, including that it is inherently transient and that it requires recurrent invasive and costly procedures over the lifetime of the patient. We have recently developed CRISPR-SKIP, a technology that utilizes base editors for disrupting the conserved AG dinucleotide within the splice acceptor of target exons. This method overcomes the problems associated with conventional exon skipping by achieving efficient and permanent exon skipping in the target cells. In our current work, we demonstrate that CRISPR-SKIP can effectively disrupt the splice acceptor of exon 45 in the dystrophin gene, a strategy that can be utilized to restore the dystrophin reading frame in patients with deletions in exons 44 or 46, which comprise approximately 9% of cases of Duchenne. First, we tested a panel of base editors that we have created and we demonstrated that they can introduce targeted base modifications in up to 90% of the targeted alleles, which is anticipated to be sufficient to provide a functional correction of DMD. Additional experiments demonstrated that targeted genome editing led to efficient skipping in mRNA and restoration of dystrophin protein expression. Furthermore, the majority of the targeting guides utilized did not induce detectable off-target mutations. Finally, to enable in vivo correction of Duchenne, we developed a split intein base editing system that is compatible with AAV delivery. We demonstrate that split intein base editors fully recapitulate the activity of their full-length counterparts at the splice acceptor of dystrophin exon 45. More importantly, split base editors delivered by AAV in vivo following intramuscular or systemic injections efficiently edited the splice acceptor of DMD exon 45. In summary, this work describes a novel exon skipping strategy that relies on base editors to enable efficient skipping of exon 45 in the dystrophin gene as well as a platform for in vivo delivery of base editing tools for correcting Duchenne muscular dystrophy.

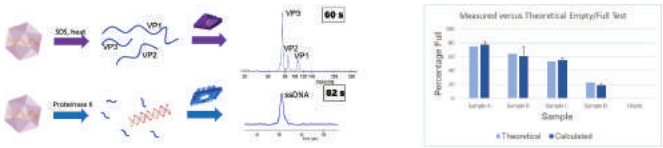
1283 Microfluidic Capillary Electrophoresis for Measurement of Full and Empty AAV Capsids

James White, Dipti Mehta

Applied Genomics, PerkinElmer, Hopkinton, MA

Adeno-associated virus (AAV) particles are intensively being investigated for therapeutic use in gene therapy due to low immunogenicity and ability for long-term gene expression in vivo. During development, testing strategies for the viral protein stoichiometry, capsid product purity, and ssDNA loading efficacy are used to monitor and assess AAV efficacy. The loading efficacy is observed as the percentage of capsids containing ssDNA (full capsids). While TEM and AUC measurements display high accuracy for empty/full measurements, these methods have high cost and time requirements. As such, there is a need for an accurate and high-throughput platform characterization system for empty/full measurement that requires low AAV volume input. Here we describe a microfluidic capillary electrophoresis method that measures AAV8 capsid proteins and ssDNA of samples alongside measurement of an AAV8 standard. Capsid protein and ssDNA area measurements are mathematically analyzed to afford the percentage full of AAV sample. The microfluidic system with AAV standard referencing method enables microliter sized samples to be analyzed in ~1 minute per sample and is concentration independent. Measurement and calculation of empty:full percentage of AAV8 samples with concordance to the expected values (within 12% of target) was achieved for sample mixtures of full and empty reference AAV particles. **Assay Overview and Experimental Setup** To determine the empty/full ratio, we began with a 10 µL fraction of AAV sample and 10 µL fraction of the AAV reference standard (75% full, UV-Vis). 5 µL of the standard and sample are mixed with a proteinase K/urea solution that upon heat treatment, digests the viral protein capsid. Microfluidic Capillary Electrophoresis (LabChip® GXII Touch™) is run using a single strand nucleic acid-binding dye for laser-induced fluorescence detection for ssDNA measurement. The remaining 5 µL of the AAV sample and reference sample are then mixed with 7 µL of a protein denaturing solution. Heat treatment and subsequent adjustment of the ionic strength prepare the solution for measurement of VP3 concentration. The percentage of full capsids was determined using an algorithm with inputs of the sample ratio of VP3 area, sample ratio of ssDNA area and the known percentage full content of the AAV8 reference standard. **Results**The average percentage full of duplicate measurements for Vigene AAV samples were found to be within 4.4% of the theoretical value for samples containing 50-75% full capsids, and all values obtained were within 12% of the theoretical value. The error for Vigene C sample was 18.8% (Target 23% full, measured 18.7% full). Sirion Biotech AAV8 samples were also made via mixing to produce different levels of full capsids. Analysis of these samples yielded an average error of 8.3% from expected. Control samples composed of 100% empty capsids did not show any measurable ssDNA signal above baseline and were calculated to be 0% full. A plot of calculated empty/full ratio versus the theoretical empty full ratio yields a linear regression R2 value of 0.96. **Conclusion** The microfluidic capillary electrophoresis-based method enables the rapid determination of the empty:full ratio for AAV8 particles. AAV8 samples can be assessed for empty/full ratio with protein and ssDNA measurements in ~1 minute per run. 10 µL samples with at least 1E12 VP/mL are recommended for use, however the exact

concentration of starting material does not need to be known. The LabChip® GXII Touch™ method provides a fast and cost-effective way to determine the empty/full ratio for AAV8 capsids.



1284 Optimizing Intravitreal Delivery to the Non-Human Primate Retina with Machine-Guided AAV Capsid Design

Shireen Abesteh, Ian Brenckle, Zac Cargill, Ina Chen, Sam Chen, Daniela Deny, Jumana Fathima, Jeff Gerold, Arpan Ghosh, Jacob Grush, Eric Kelsic, Helene Marie Kuchwara, Jamie Kwasnieski, Kathy S. Lin, Erik A. Dyno Therapeutics, Watertown, MA

To enable transduction of deeper retinal cell layers, current AAV-mediated ocular gene therapies require high doses to achieve clinically relevant efficacy which increases the risk of adverse inflammatory responses, or employ subretinal injections that must be performed by trained surgeons. More efficient cell-type targeted pan-retinal transduction via intravitreal (IVT) administration would allow for more effective therapies at lower and safer doses, broadening the reach of ocular gene therapies. Using machine-guided design we generated variant capsids with up to 80 times more efficient transduction of the neural retina in non-human primates (NHP) following IVT delivery as compared to AAV2. We then evaluated cell-type specific transduction patterns in the neural retina by single-nucleus RNA-seq. Relative to an AAV2-derived literature variant reported to have improved retinal transduction, these capsids demonstrated 2-6x improvement in retinal cell types including rods, cones, microglia and retinal ganglion cells. Extrapolating to a conservative dose of 8.0e10 vg/eye, we infer that these variants are capable of transducing a high proportion of cells across retinal cell types, for example up to 17% in retinal ganglion cells. The true proportion of transduced cells is likely even higher due to incomplete capture of transduction events in single nucleus sequencing. We selected one top capsid for further validation and injected it intravitreally into NHP eyes. Qualitative and quantitative in-life and histological readouts for transduction properties were performed based on reporter transgene expression. Histological readouts confirmed the variant's significantly improved transduction efficiency compared to AAV2-derived literature variants. These results show the utility of single-molecule based NGS-based readouts in both library and validation contexts and demonstrate the power of applying machine learning to capsid design.

1285 Gene Editing Therapy in a Humanized Mouse Model of Amyotrophic Lateral Sclerosis

Linyu Shi[1], Dong Yang[1], Xiaoqing Wu[1], Hui Yang[1,2]

[1]HuidaGene Therapeutics Co., Ltd., Shanghai, China,[2]Center for Excellence in Brain Science and Intelligence Technology, Chinese Academy of Sciences, Shanghai, China

Background: Amyotrophic lateral sclerosis (ALS) is a late-onset fatal neurodegenerative disease with an incidence rate of approximately 2-5 per 100,000 people in Europe and the United States. The neuropathological hallmark of ALS is the degeneration of cortical and spinal motor neurons with common symptoms such as muscle weakness, twitching, cramping, dyspnea, and dysphagia, leading to respiratory failure, paralysis, and death, typically within 2 to 5 years of symptom onset. About 10% of ALS patients are familial, and most of them are caused by the mutations in genes such as *C9orf72, SOD1, TDP-43,* and *FUS*. The dysfunctional protein aggregated in neurons is central to the pathology of ALS, and 97% of ALS patients eventually show the accumulation of mutated TDP-43 protein in the cytoplasm. TDP-43 is a DNA/RNA-binding protein essential for normal functions of the upper and lower motor neurons. It was reported that *ATXN2* promotes the formation of stress granules involving TDP-43 protein, and knockdown of *ATXN2* effectively inhibits the formation of stress granule aggregates by TDP-43. Hence, *ATXN2*-targeting gene editing is one of the potential treatment strategies for ALS. **Methods**: To explore the therapeutic effect of single AAV vector packaging high-fidelity Cas12i (hfCas12Max) and gRNAs targeting *Atxn2* (gAtxn2), we administrated AAV-hfCas12Max-gAtxn2 in postnatal day 0-1 humanized *TDP-43* transgenic mice via intracerebroventricular (ICV) injection (Fig. 1A). The indel efficiency was tested by PCR plus NGS sequencing. ATXN2 protein level in the cortex was evaluated by western blot and immunofluorescence staining. The lifespan of humanized *TDP-43* transgenic mice with or without AAV-hfCas12Max-gAtxn2 was also observed daily. **Results**: In the neonatal humanized *TDP-43* transgenic mice, the indel ratio of *Atxn2* gene reached 46.1% (Fig. 1B), and the knockdown efficacy of ATXN2 protein level was up to 86.8% in the cortex at 2 weeks post infection with AAV-hfCas12Max-gAtxn2, compared with that in control mice (Fig. 1C-E). Median survival of humanized *TDP-43* transgenic mice injected with high-dose AAV-hfCas12Max-gAtxn2 (29.75±0.5 days) was 5 days longer compared with humanized *TDP-43* transgenic mice injected with PBS (25.29±0.99 days), representing a 20% extension of survival (Fig. 1F). **Conclusions:** Our findings provide a strong foundation and promising approach for the clinical application of AAV-hfCas12Max-gAtxn2 to treat ALS, which may potentially increase the lifespan of patients with ALS.

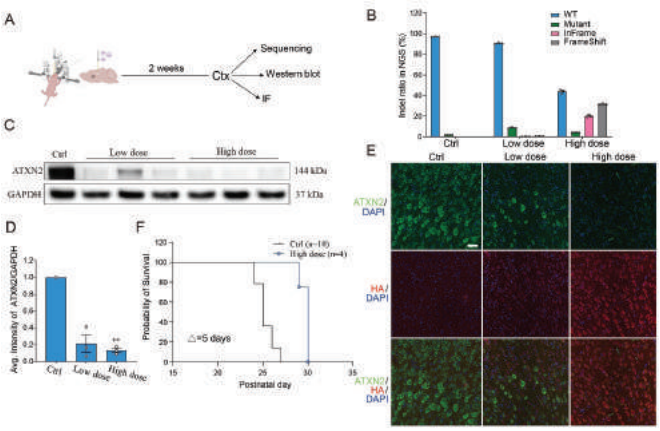

Figure 1. The treatment effect of AAV-hfCas12Max-gAtxn2 in the humanized *TDP-43* transgenic mice

1286 Combined +58 and +55 *BCL11A* Enhancer Editing Yields Exceptional Efficiency, Specificity and HbF Induction in Human Hematopoietic Stem Cells

Jing Zeng[1], My Anh Nguyen[1], Marioara-Felicia Ciuculescu[1], Esther Mintzer[2], Pengpeng Liu[2], Linda Lin[1], Tolulope Rosanwo[1], Archana Verma[1], Nola Neri[1], Stacy Maitland[2], Alden Richter[2], David Justus[1], Kendell Clement[3], Christian Brendel[1], Luca Pinello[3], John Manis[1], Myriam Armant[1], Scot Wolfe[2], Daniel Bauer[1]

[1]Boston Children's Hospital, Boston, MA,[2]University of Massachusetts Medical School, Worcester, MA,[3]Massachusetts General Hospital, Boston, MA

Targeting the *BCL11A* erythroid enhancer by gene editing is a promising approach to fetal hemoglobin (HbF) induction for β-hemoglobinopathies. HbF levels vary widely among individuals. We hypothesize that maximizing HbF induction potential could maximize clinical benefits. Here we compared CRISPR-Cas9 endonuclease editing of the *BCL11A* +58 enhancer with alternative gene modification approaches, including +55 enhancer editing alone or in combination with the +58 enhancer, as well as editing targeting the *HBG1/2* promoter -115 BCL11A binding site and transduction by an shRNA knocking down the *BCL11A* transcript in erythroid precursors. We found that combined editing of the +58 and +55 enhancers with 3xNLS-SpCas9 and two sgRNAs resulted in the most potent HbF induction (52.4%±6.3%) of the tested approaches (*BCL11A* +58 editing alone, 29.1%±3.9%; *BCL11A* +55 editing alone, 34.8±5.1%; *HBG1/2* promoter editing, 34.1% ±5.4%; shmiR-*BCL11A*, 32.2%±4.4%; mock, 7.6%±3.4%). Based on bulk and clonal analyses, we found that disruption of core half E-box/GATA motifs at both the +58 and +55 enhancers was associated with greatest enhancer chromatin inaccessibility and HbF induction, whether by small indels, interstitial 3.1 kb deletion or 3.1 kb inversion. Combined editing of +58 and +55 enhancers was compatible with HSC self-renewal and multilineage repopulation in primary and secondary xenotransplantation. We developed conditions using a MaxCyte electroporation instrument achieving mean 97.3±1.8% gene edits in 3 engineering runs at clinical scale, with similar results at small-scale with plerixafor-mobilized HSPCs from sickle cell disease (SCD) donors or G-CSF mobilized PBMCs from transfusion-dependent beta-thalassemia (TDT) donors, including 94.2%±4.4%, 99.5%±0.3% and 91.8%±6.3% of gene edits in engrafting cells from NBSGW 16 week mouse bone marrow of healthy, SCD and TDT donors respectively. Off-target analyses by pooled amplicon sequencing of 1288 candidate off-target sites for the +58 and +55 targeting sgRNAs, nominated by a range of computational (CRISPRme) and experimental (GUIDE-seq and ONE-seq) methods, did not identify reference genome off-target edits at a sensitivity of 0.1% allele frequency. We found the fraction of micronuclei was increased in cells electroporated with RNP following 24 or 48 hours of cytokine stimulation but not in unstimulated cells. We observed ~9-fold enrichment of chr2p in micronuclei after 24 or 48 hours of pre-stimulation cytokine culture prior to gene editing, but did not observe enrichment of chr2p in micronuclei in cells edited without pre-stimulation culture, suggesting that chromosome mis-segregation could be avoided by editing quiescent HSCs. We found editing cells without pre-stimulation culture was associated with undetectable long deletions and rearrangements as compared to editing after 24 or 48 hours of pre-stimulation culture. We observed similar HbF levels, editing and engraftment potency without as compared to with cytokine culture across mobilization type (G-CSF or plerixafor), donor disease status (healthy and SCD), and sgRNA target sequence. Together these results suggest that combined *BCL11A* +58 and +55 enhancer editing without cytokine culture produces highly efficient on-target allelic disruption, heightened HbF induction capacity compared to alternative approaches, preserved long-term multilineage engraftment potential, and absence of evident genotoxicity, under clinically relevant SpCas9 RNP electroporation conditions.

1287 Characterization of Genomic Heterogeneity in rAAV Preparations Using Short- and Long-Read Next Generation Sequencing

Tina Strauss[1], Alpha B. Diallo[2], Irene Zolotukhin[1], Elizabeth Tseng[3], Kristina Weber[3], Matthew Burg[1], Nilay Patel[4], Brett Palaschak[1], Stewart Coleman[5], Jennifer L. Marlowe[6], Adam S. Cockrell[1]

[1]Solid Biosciences, Gainesville, FL,[2]Form Bio, Dallas/Austin, TX,[3]Pacific Biosciences, Menlo Park, CA,[4]Solid Biosciences, Durham, NC,[5]Solid Biosciences, San Antonio, TX,[6]Solid Biosciences, Charlestown, MA

Three approved gene therapies within the last 6 years demonstrate that recombinant adeno-associated viral (rAAV) vector products are an accepted modality for delivering therapeutic transgenes to correct monogenic disorders. As commercial scale is needed to support the demand for AAV therapies there may be a need to manufacture large, reproducible batches of AAV drug products that are safe, pure, and potent. Biological outcomes associated with these attributes may be influenced by the genetic heterogeneity within populations of rAAV vector preparations. Molecular profiling of the genetic heterogeneity within rAAV vector preparations can provide insight into batch-to-batch reproducibility and inform on vector modifications that can improve these attributes. We applied long-read and short-read next generation sequencing (NGS) as orthogonal methods for molecular profiling of rAAV vector preparations. Our results demonstrate that

genetic composition can be influenced by choice of AAV capsid, method of producing AAV vectors, vector design, and downstream purification method. Learnings from rAAV molecular profiles will be processed by a unique artificial intelligence (AI) platform which can inform iterative vector designs.

1288 Development of AAV Transduction and Potency Assays to Evaluate Quality Attributes of ASC618, a Second Generation AAV8-Based Hemophilia A Gene Therapy

Chengtao Yang, Yu-Chen Sun, Eliza Dewangan, Yin Zhang, Rong Chen, Avital Gilam, Milena Veselinovic, Steve Zhang, Zoya Gluzman-Poltorak, Ruhong Jiang
ASC Therapeutics, Milpitas, CA

ASC618 is a second generation of AAV8-based gene therapy for Hemophilia A under clinical development. It utilizes an optimized liver-specific promoter to express an engineered human Factor VIII variant (ET3-FVIII) that is secreted with high efficiency from hepatocytes. To support the ongoing Phase 1/2 clinical trial that evaluates the safety, tolerability, and preliminary efficacy of ASC618 (NCT04676048), we have established robust analytical methods to assess the quality attributes of ASC618 GMP lots. We have developed a ddPCR-based AAV transduction assay to evaluate relative infectivity of ASC618 GMP lots in HepG2 cells (a human liver cancer cell line), compared to a reference standard (ASC618 Engineering Lot). During method development of the transduction assay, we observed that the transduction efficiency, measured by a ddPCR assay specific for theET3-FVIII transgene in ASC618-transduced HepG2 cells, strongly correlated with the level of ET3-FVIII protein in the cell culture media. Therefore, a single preparation of ASC618-transduced HepG2 cell culture can be used for both the transduction assay (using HepG2 cell pellets) and the potency assay (using cell culture supernatant), which streamlines the analytical workflow and reduces the amount of drug substance (DS) and drug product (DP) required for testing. The potency of ASC618 GMP lots relative to that of a reference standard (ASC618 Engineering Lot), which is evaluated by two assays that we have developed: a Potency-ELISA assay and a Potency-Activity assay, which XYNTHA® Antihemophilic Factor VIII (Recombinant) was used to generate standard curves for both assays. In pre-qualification experiments, the ASC618 Engineering lot was applied as Reference Standard and used to prepare QC samples with target ratio of potency (TRP) of 0.5 (50% QC), 1 (100% QC), 1.5 (150% QC) and 2 (200% QC) respectively. Both the Potency-ELISA Assay and the Potency-Activity Assay exhibited accuracy within 30% for TRP 0.5 - 2. In addition, by dividing the Potency-Activity result (IU/mL) by the Potency-ELISA result (IU/mL), we observed that the ET3-FVIII in the HepG2 cell culture supernatant has relative activity of 87.8% ± 20.4% to XYNTHA® Antihemophilic Factor VIII (Recombinant). By using the transduction, Potency-ELISA, and Potency-Activity assays, three independent batches of ASC618 drug substance (DS) or drug product (DP) have been tested. The relative transduction confirmed high consistency with the relative potency in both ELISA and Activity assays.

1289 Promoter Triage for Gene Expression & Function Optimization

Shen Lu, Christopher B. Driscoll, Kelsey Dupont, Emmanuel Nekongo, Alexander Boucher, Andrew Basinski, Elise Kim, Ana Maria Chadbourne, Cherylene Plewa, Stacie Seidel
Cellular Engineering, ElevateBio, Waltham, MA

Optimizing lentiviral vector designs to increase titer, decrease production costs, and increase potency is an active area of exploration especially for vectors entering large scale manufacture. Here, we tested the effect of different promoters on multiple CAR and transgenic TCR constructs for their effect on titer, integration, expression, and in vitro function. To achieve this, we developed a scaled down mid-throughput lentiviral vector production platform to produce multiple constructs in tandem with sufficient titers for functional screening. We found that the MND promoter was able to ubiquitously produce high titers of lentiviral vector and generated a high level of expression across all CAR and TCR constructs tested. Interestingly, EF1αL consistently produced lower titers compared to MND based constructs, but when transduced at the same MOI produced high levels of expression in T cells. Conversely, the SFFV and MSCV promoters showed varying titers and expression dependent on the encoded gene of interest. Comparing viral copy number and expression data, we were able to evaluate transduction efficiency and surface expression levels separately for each gene of interest. Unsurprisingly, cytotoxicity and function of each construct tested was highly correlated to the expression level on the cell surface in most cases. These data will help guide future construct design and help streamline clinical candidates towards scale and up feasibility studies.

1290 Optimization of a Virus-Free CRISPR-Cas9 Based Platform to Produce Allogeneic Chimeric Antigen Receptor (CAR) T Cells

Sarah Caroline Gomes de Lima[1], Dan Cappabianca[2], Matthew Forsberg[2], Christian Capitini[2], Dimas T. Covas[1], Krishanu Saha[2], Lucas E. B. de Souza[1]
[1]University of São Paulo, Ribeirão Preto, Brazil,[2]University of Wisconsin-Madison, Madison, WI

Autologous T cells expressing the chimeric antigen receptor (CAR) represented a breakthrough in hematological malignancies' treatment, leading to remission rates as high as 90%. Despite the impressive success, the custom-made pattern of such therapy restrains its widespread applicability due to defective cellular characteristics of intensively pretreated patients, complex production logistics and cost. Allogeneic T cells from healthy donors became an excellent alternative as a starting material for CAR T cell manufacture, enabling a staggered production of ready-to-use doses. Challenges of the resulting HLA-mismatched CAR T cell therapy can be addressed through T cell receptor (TCR) knock-out using genome editing technologies to prevent the graft-versus-host disease development. Here we described an optimization process of the CRISPR/Cas9 tool for a streamlined virus-free CAR T cell manufacture. With so, we targeted a transgene integration into the *TRAC* (*T Cell Receptor Alpha Constant*) locus, consequently disrupting the TCR. For the CRISPR/Cas9-mediated knock-in, we provided a homology-directed repair template (HDRT)

containing a second-generation anti-CD19 CAR or a mCherry sequence flanked by homology arms to the desired cut site in the human *TRAC* locus. This sequence was PCR amplified and purified, resulting in a highly concentrated double-stranded DNA HDRT, which was electroporated with the Cas9 ribonucleoproteins (RNPs) into healthy donors' T cells. Cells were assayed on days 5 and 11 post-electroporation for CAR expression and killing efficiency, respectively. We observed a 1.3-fold (±0,2) improvement in mCherry knock-in by adding the negatively charged polymer poly-L-glutamic acid (40 μg) that binds to RNPs and reduces aggregates (**Fig. 1A**). Additionally, by culturing the electroporated cells with increasing concentrations of an NHEJ inhibitor, we achieved a 1.3 (±0,1) to 2-fold (±0,02) increase in the editing efficiency (**Fig. 1B**), suggesting a favorable condition for the HDR. We then electroporated T cells with the CAR HDRT (3.2 kb length, 25 μg) using the established optimized conditions. We got high levels of TCR knock-out (91,5±0,4%) and CAR knock-in (83,7±4,0%) five days after electroporation (**Fig. 1C**), with the viability reaching ~60% on day 7. The on-target CAR gene integration was confirmed through an "in-out" PCR assay on the genomic DNA using primers specific to the *TRAC* locus and CAR transmembrane domain. In vitro potency of CAR T cells was measured by coculturing them with GFP-expressing RS4-11 cells ($CD19^+$). We observed a consistent control of the tumor cell growth at a 1:1 effector-to-target ratio (**Fig. 1D**), demonstrating the robust antitumor function of the CAR T cell products. Combined, the data provide a proof-of-concept for the virus-free manufacturing process of allogeneic anti-CD19 CAR T cells, enabling CAR knock-in and TCR knock-out in a single-step approach.

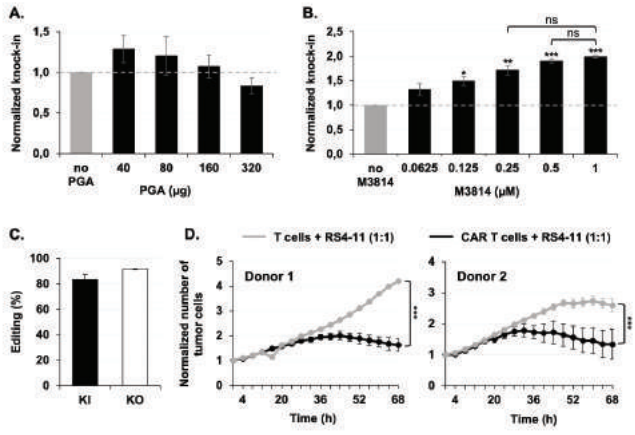

Figure 1. Improvement in mCherry knock-in rates using the anionic polymer poly-L-glutamic acid (PGA, **A**) and an NHEJ inhibitor (M3814, **B**). (**C**) Editing rates (CAR knock-in, KI; TCR knock-out, KO) 5 days after electroporation. (**D**) Tumor cell growth inhibition was observed for a 1:1 effector-to-target ratio. ns≥0,05; * p≤0,05; ** p≤0,01; *** p≤0,001.

1291 Development of Metabolically Reprogrammed HER2-CAR T Cells Suitable for Treating Breast Cancer

Kevin Song[1], Xiaotong Song[2]

[1]Biology, University of Houston, Houston, TX,[2]Texas A&M University, Houston, TX

HER2-targeted therapy is an established method for treating HER2-positive breast cancer. HER2 antibody-drug conjugate (ADC) is the newest additions to HER2-targeted therapy with Trastuzumab emtansine and Trastuzumab deruxtecan being recently approved by the FDA. Trastuzumab deruxtecan has shown to be effective in treating HER2-low breast cancer, allowing it to be the first targeted therapy for HER2-low breast cancer approved by the FDA. Although HER2 ADC drugs show effectiveness in killing HER2-positive breast cancer, the vast majority of HER2 ADC drugs result in a variety of side effects, with most being high grade or serious side effects. HER2 ADC's safety profile is similar to chemotherapy in several adverse events (AE), with two AEs of special interest (left ventricular dysfunction and interstitial lung diseases/pneumonitis) occurring more frequently in HER2 ADC drugs than it does in chemotherapy. Among these AEs, lung toxicity is an important safety concern of HER2 ADC drugs. Therefore, there is a need for a novel effective HER2-targeted therapy with lower toxicity. Remarkably, recent clinical studies demonstrated that the second generation HER2-CAR T cell with CD28 co-stimulatory domain showed lower toxicity with little incidents of grade 3 or higher adverse side effects, while having certain antitumor activity in early phase of clinical studies of HER2-positive Sarcoma and Glioblastoma. In this study, we developed and demonstrated the effectiveness of a metabolically reprogrammed HER2-CAR (MR.HER2-CAR) T cells that overexpress a secreted adenosine deaminase 1 (ADA1) fused with an anchor and CD26 (the receptor of ADA1) on the cell surface and. The ADA1 converts adenosine to inosine, allowing for the MR.CAR T cells to overcome adenosine-mediated immunosuppression and to provide inosine for CAR T cell growth. ADA1 is a cytoplasmic protein and conditionally secreted under stress, suggesting that ADA1 activates CAR T cells as a trans-signaling in a tumor specific manner. The overexpressed CD26 induced a rich chemokine receptor profile, allowing the CAR T cells to traffic to solid tumors. We further demonstrated that these MR.HER2-CAR T cells are more effective in killing HER2-low breast tumor cells than unmodified HER2-CAR T cells. Thus, MR.HER2-CAR T cell therapy is a promising candidate for a novel HER2-targeted therapy that is effective while having low toxicity.

1292 AAV Mediated Expression of a Chimeric Ion Channel in Combination with Its Ligand Varenicline Demonstrates a Dose Response Improvement in Pain Hypersensitivity in a Rat Model of Trigeminal Pain

Rosemarie Roeloffs[1], Ira Liolis[1], Nino Devidze[2], David Bleakman[2], David Spanswick[3], Fei-Yue Zhao[4], Haifeng Wei[4], Matilde P. C. B. da Cruz[4], Wendy Imlach[5], Melissa Rhodes[1]

[1]Kriya Therapeutics, Inc., RTP, NC,[2]Redpin Therapeutics, NYC, NY,[3]University of Warwick, Coventry, United Kingdom,[4]NeuroSolutions Ltd, Coventry, United Kingdom,[5]Monash Univerity, Melbourne, Australia

Chemogenetics is a method that provides selective control of cellular function by installing an engineered receptor that renders a targeted cell population sensitive to a small molecule ligand. KT-74863 is an AAV vector designed to drive expression of an engineered ligand-gated ion channel that is activated by the FDA approved drug varenicline to open a chloride-conducting ion channel that results in decreased neuronal excitability. KT-74863 in combination with varenicline (KT-74863-VT) is being developed for the treatment of trigeminal neuralgia. Trigeminal neuralgia (TN), also known as tic douloureux, is a rare, chronic and debilitating facial pain disorder that can be difficult to treat. Approved medications are poorly tolerated and lose their effectiveness over time, while surgical options are often complex, can be highly invasive and result in high rates of sensory loss. The pain is thought to be due to damage of the trigeminal roots or ganglion that results in hyperexcitability of the trigeminal nerve, giving rise to pain paroxysms. Control of hyperexcitability of neurons is affected primarily by the activity of membrane associated ion channels, whereby influx of anions through these channels leads to neuronal hyperpolarization and a decrease in pain. KT-74863-VT is expected to decrease trigeminal hyperexcitability following focal administration to the trigeminal ganglion and is being developed as a one-time treatment option for patients with TN who are refractory to medication. The preclinical efficacy and durability of KT-74863-VT was evaluated in the rat infraorbital nerve chronic constriction injury (IoN-CCI) model, an established model of trigeminal pain. Two treatment paradigms were tested: IoN-CCI surgery before or after KT-74863 administration. Efficacy was measured using a series of von Frey hairs applied to the whisker pads to determine the escape threshold (ET). Transgene expression was also measured in the trigeminal ganglion. KT-74863-VT in IoN-CCI male and female rats demonstrated a dose responsive improvement in pain hypersensitivity and durability regardless of treatment paradigm. Efficacy was observed throughout the 6-month duration of the study. The escape threshold (ET) significantly improved in both male and female IoN-CCI rats with no significant differences in ET between sexes. In contrast, neither KT-74863 alone nor varenicline alone demonstrated reductions in pain sensitivity. Analysis of relative levels of KT-74863 viral DNA and GlyR mRNA demonstrated dose dependent DNA/mRNA expression in the injected trigeminal ganglion. Varenicline levels in all animals receiving treatment were within predictable levels at the time of sample collection.

1293 Through the Ups and Downs - Leveraging siRNA-Mediated Gene Knockdown to Influence the Productive Capacity of HEK293 Cells in rAAV Production

Niklas Kraemer[1,2], Kathrin Teschner[1], Vera Ortseifen[1], Alyssa Vetter[1], Franziska Sundermann[1], Sandra Klausing[1]

[1]Research and Development, Sartorius Xell GmbH, Bielefeld, Germany,[2]Faculty of Technology, Bielefeld University, Bielefeld, Germany

Recombinant adeno-associated viruses (rAAV) have become one of the dominant forms of viral vectors for *in vivo* gene therapy. A growing body of work has focused on identifying new principles and methods to increase the yield in rAAV production. Despite this, many aspects of the molecular mechanisms underlying rAAV production by the host cell are still elusive. The complex networks of signaling pathways, messenger compounds and effectors are not yet fully understood and therefore not trivial to manipulate. Here we show how next-generation sequencing can be used to identify targets for cell line engineering of rAAV producer cell lines. Transcriptomic analysis was performed on RNA-Seq data from two different commercially available HEK293 cell lines. Cells were transfected with a two-plasmid system, collected 18 h afterwards and total RNA was sequenced. Bioinformatic tools such as DESeq2, Clusterprofiler and Reactome PA were employed for gene expression and pathway analysis to identify target genes that might affect the cellular production capacity for rAAV. In total, 4,008 genes were differentially expressed between the two cell lines. These genes belonged to 872 significantly enriched GO terms, covering numerous cellular mechanisms that were deemed relevant for rAAV production. One promising gene from this set was selected for assay establishment and as a proof-of-concept candidate. As a main aspect, we present the Design of Experiments-assisted steps towards siRNA transfection optimization for suspension cells, comparing different reagents, ratios, and conditions. The suspension-based assay is performed in a scale-down approach in 24-well plates. Based on the optimized protocol, we showed the effect of the siRNA-mediated gene knockdown on growth performance, transfection efficiency and rAAV titer. This work demonstrates how data-driven approaches can facilitate further developments in cell line engineering and help increase rAAV production capacities.

1294 High Throughput Viral Vector Characterization Using Density Gradient Equilibrium Analytical Ultracentrifugation (DGE-AUC)

Akash Bhattacharya[1], Shawn M. Sternisha[2], Ross VerHeul[2], Abraham Wilson[2]

[1]Beckman Coulter Life Sciences, Loveland, IN,[2]Beckman Coulter Life Sciences, Indianapolis, IN

Introduction to viral vector characterization and quality control: Quality control of gene therapy vector like adeno-associated virus (AAV) relies on a battery of biophysical techniques such as Anion Exchange Chromatography (AEX), Transmission Electron Microscopy (TEM), UV spectroscopy, light scattering, mass photometry (MP) and Sedimentation velocity Analytical Ultracentrifugation

(SV-AUC); the last of which is considered the gold standard for quantification of empty vs partially loaded vs fully loaded AAV capsids (E/P/F ratio). Here, we present a new method called Density Gradient Equilibrium Analytical Ultracentrifugation or DGE-AUC to characterize Adenovirus, AAV and other gene therapy products.
DGE-AUC: DGE-AUC operates on the same principles as density gradient ultracentrifugation (DGUC): i.e, analyte particles are subjected to ultracentrifugation in the presence of a density gradient-forming material such as CsCl. At equilibrium, the CsCl forms a radial gradient of increasing density. Every analyte particle migrates to the radial position where the local density of CsCl corresponds to its own density. Thus, at equilibrium - empty, partially loaded and fully loaded capsids which have increasing density migrate to and accumulate in the form of bands at increasing radial positions.
Advantages of DGE-AUC and comparison to SV-AUC:
• ***Separation basis:*** DGE-AUC separates analytes only on the basis of particle density, while SV-AUC separates particles on the basis of sedimentation coefficient, which is a function of particle size, shape and density. Thus, DGE-AUC is an orthogonal technique to SV-AUC.
• ***Simplified analysis:*** The analysis of DGE-AUC data does not require specialized software (unlike SV-AUC). The output from a DGE-AUC experiment can be visually interpreted intuitively and analyzed similarly to a chromatogram. Quantification of different capsid species (E/P/F ratio) is achieved by identifying and integrating the peaks corresponding to the different species.
• ***Low sample consumption:*** DGE-AUC provides high resolution separation with significantly less sample (> 30-fold sensitivity) than SV-AUC.
• ***High throughput:*** DGE-AUC experiments can be completed within a couple of hours. Useage of 6 sector AUC centerpieces (as opposed to the 2 sector centerpieces used in SV-AUC) increases throughout. Here, we demonstrate a high throughput adenovirus packaging analysis experiment, running as many as 21 samples in 80 minutes.
• ***Flexibility with samples:*** SV-AUC requires relatively pure samples. DGE-AUC works with in-process dirty samples as well.
• ***No size limitation:*** SV-AUC is not suitable for large analytes such as Adenovirus and other large viral vectors that sediment rapidly without providing enough scans for analysis. DGE-AUC effectively has no size limitations w.r.t. particles and can be applied to these samples.
• ***Multiwavelength (MWL) experiments:*** SV-AUC experiments with MWL scans require more time for data acquisition, which is not always available for large samples that sediment quickly. MWL-DGE-AUC can acquire additional scans at different wavelengths after equilibrium has been established, which provide more fine-grained information on the capsid nucleic acid content.

1295 Determining the Efficacy and Mechanism of NKG2D-Based CAR T Cells

Jana Obajdin[1], David Marc Davies[2], John Maher[2,3], Daniel Larcombe-Young[1,2]

[1]Research Oncology, King's College London, London, United Kingdom,[2]Leucid Bio, London, United Kingdom,[3]King's College London, London, United Kingdom

Chimeric antigen receptor (CAR) T-cells are genetically modified to specifically target tumour-associated cell surface targets. Despite clinical success in patients with haematological cancers, their competence against solid tumours is hindered by an immunosuppressive environment, and further understanding of the functionality of these cells is required to improve potency and scope of treatable cancers. We have investigated the use of NKG2D as a device to target CAR T-cells against stress ligands that are commonly expressed on solid tumour cells. This concept was originally developed by Sentman et al. More recently, several other groups have explored the use of second-generation CARs targeted by NKG2D with a view to improve anti-tumour activity. Clinical development of NKG2D-targeted CARs is currently being led by Celyad Oncology in a number of indications. However, a systematic comparison between the function and mechanistic properties of NKG2D-targeted CARs has not been undertaken. In my project, I compared a panel of second generation NKG2D-based CARs, with differing structures and sources of signalling moieties. They were assessed for their ability to re-target T-cell specificity against solid tumour cell lines. *In vitro*, they were assessed for their ability to continuously re-stimulate on cell lines, exerting cytotoxicity and secreting pro-inflammatory cytokines for several cycles. Additionally, T cells were phenotypically characterised both in culture and after tumour cell stimulation. Anti-tumour activity was additionally assessed in preclinical models using NSG mice bearing established xenografts, using both intraperitoneal/intraperitoneal (i.p/i.p) and subcutaneous/intravenous (s.c/i.v) models. Tumour burden was assessed using bioluminescence imaging to monitor disease status for the i.p/i.p model, and using calliper measurements to define tumour growth in the s.c/i.v model. NKG2D-based CAR T cells were also subject to bulk RNA sequencing post stimulation, with the aim of uncovering mechanistic insights into the functionality of these CAR T cells, including mechanisms governing their differentiation, cytolytic capacity, intracellular signalling, and metabolic status. We will present a comparative analysis of NKG2D targeted CAR T-cells in which CAR configuration and the source of stimulatory domains have been modified to assess their importance in overall function.

1296 High Systemic Dosing of an Engineered rAAV9 with TLR9 DNA-Based Immunomodulatory Sequence Allows Higher and Persisting Transgene Expression in Rats

Mickael Guilbaud, Laure Carre, Samer Masri, Nicolas Jaulin, Johanne LeDuff, Manon Lucas, Anthony Mellet, Manon Loirat, Gwladys Gernoux, Virginie Pichard, Oumeya Adjali

Nantes University, Nantes, France

Recombinant adeno-associated virus-derived vectors (rAAV) have become an essential part of the gene therapy landscape. Despite the growing successes, the immune response directed to the vector and/or the transgene product nevertheless appeared in patients as a major limitation for a successful clinical translation of systemic rAAV products. One way to overcome rAAV-directed immune response is to prevent their initiation through the inhibition of the innate immune system activation. Several pattern recognition receptors (PRR) have already been described to detect pathogen-associated molecular patterns (PAMPS) present either in the capsid or the viral vector genome itself. Among them, the Toll-like-receptor 9 (TLR9) is shown to play an important role

in the detection of unmethylated CpG dinucleotides contained in the vector genome. Moreover, its inhibition by an antagonistic sequence added to the rAAV viral genome is reported to have an immunomodulatory effect on transgene expression after gene transfer. Here, we evaluated the effect of a novel engineered rAAV9 genome carrying a TLR9 DNA-based immunomodulatory sequence (TLR9 DIMS) after high systemic vector dosing. After *in vitro* validation, our TLR9 DIMS sequence was inserted in the vector genome of a rAAV9 cassette expressing the reporter gene Green Fluorescent Protein (GFP) and intravenously administered in rats at 1e14 vg/kg. Biodistribution and immunogenicity analyses were performed at three months after injection. Results didn't show any significant difference in anti-capsid humoral and cellular immune responses in presence of rAAV9 containing TLR9 DIMS. However, anti-GFP antibody titers were found lower with the engineered vector as compared to the control. Moreover, by RT-qPCR, we determined that rAAV9-TLR9 DIMS was correlated to significantly higher levels of transgene transcripts in skeletal muscles, heart and liver. Finally, the expression of the transgene was maintained until at least 3 months post-injection in the liver of all rats injected with rAAV9 TLR9 DIMS (6/6) *versus* 6/9 in the control group. In conclusion, although there was no impact on anti-capsid immunogenicity, our rAA9 TLR9 DIMS-engineered vector significantly increased the efficiency of gene transfer when injected at systemic high doses and allowed the maintenance of transgene expression. These findings confirm that rAAV engineering with immunomodulatory sequences holds a great promise to suppress or at least modulate rAAV immunogenicity while allowing persisting transgene expression.

1297 Shortening Lentivirus Process Development Timelines Using a Templated Approach

Joe S. Orlando

MilliporeSigma, Bedford, MA

The field of Lentivirus GMP manufacturing is relatively new, with only a handful of existing therapies on the market today. However, the success of these life-saving therapies is potentiating the development of novel Lentivirus-based therapies and supporting a growing need for Lentivirus GMP manufacture. Further, the timelines for getting regulatory-approved novel therapies to the clinic are compressed due to factors such as patient outlook and the competition. There is a need in the industry to simplify the path to rapid, robust, and compliant manufacture of Lentivirus-based therapeutics. To address the key drivers of Lentivirus manufacturing, we developed a vendor-agnostic, standard manufacturing template containing beginning-to-end guidelines to ensure that the process meets Upstream and Downstream performance metrics, raw materials meet compliance requirements and timelines are predictable. Here we show a case study using this Lentivirus manufacturing template for a model therapeutic. Using DOE-based approaches, we show rapid optimization of Upstream BioProcessing and achieved harvest titers of >5x10^{8}TU/ml. The template permitted rapid and efficient scale-up to 50L scale and generation of high titer material for purification. Using pre-determined template parameters, we were able to obtain efficient recovery of the product with limited iterations. Step recoveries of each step in the Downstream process will be shown. The collective reduction of process development time using this Lentivirus template containing established protocols and compliant raw materials enables rapid manufacture and delivery of life-saving therapies to patients.

1298 Development of a 3-Day DashCAR-T Cell Therapy Against C-Type Lectin-Like Molecule 1 (CLL-1) for Acute Myeloid Leukemia

Chien-Tsun Kuan[1,2], Kao-Jean Huang[1], Alex Chang[1], Hom-Ming Yeh[1], Shun-Jen Yang[1]

[1]ARCE Therapeutics, Taipei, Taiwan,[2]Pathology, Duke University Medical Center, Durham, NC

Acute myeloid leukemia (AML) characterized by overproduction of immature myeloid cells in the bone marrow is the most common acute leukemia in adults and the second most common leukemia in children. AML standard treatments with chemotherapy, radiation therapy, targeted therapy, and allogeneic hematopoietic stem cell transplantation (alloHSCT) had limited improvements in recent decades as the prognosis of refractory/relapsed AML remains poor and the 5-year survival rate is below 50%. Patients are in urgent need of novel therapeutic strategies. Chimeric Antigen Receptor (CAR) T cells are recognized as one of the most promising breakthrough in the treatment of hematological malignancies that mediate tumor cytotoxicity in a major histocompatibility complex (MHC)-independent manner. Human C-type lectin-like molecule-1 (CLL-1; CLEC12A) is highly expressed on differentiated myeloid cells, AML blasts and leukemic stem cells (LSCs) but not on normal hematopoietic stem cells (HSCs), suggesting that CLL-1 is a compelling target with low off-tumor toxicity for novel AML treatment. A developing CLL-1 DashCAR-T cell in the second generation CAR format, targeted with a human single-chain variable fragment (scFv) against the CLL-1 antigen, was optimized to 3 days in the manufacturing bioprocess, conferring DashCAR-T cells with characteristics of high percentage of CAR population (>80%), high percentages of memory-like phenotypes of T_{scm} and T_{cm} (>70%) and profound effector cytokine production (IFN-γ, granzyme A, perforin and granulysin) as well as specific cytotoxicity against various AML tumor cells both *in vitro* and *in vivo*. In the AML U937-Luc xenograft mouse model, the CLL-1 DashCAR-T cells with CD28 co-stimulatory domain exhibited superior anti-tumor activity than those with 4-1BB domain, and prolonged the survival time with CAR-T cell persistence more than 48 days post CAR-T cell infusion. Furthermore, the xenograft mice receiving as minimum as 3 x10^5 DashCAR-T cells per mouse were able to elicit effective recall responses after tumor rechallenge and survived for more than 60 days. In the aspect of on-target off-tumor toxicity, hematotoxicity assessment revealed that CLL-1 DashCAR-T cell candidates were well tolerated as they exerted modest colony formation inhibition of CD34+ cells derived from normal bone marrow in 5%-23% at E/T = 1 (n=3) and 1%-34% at E/T = 4 (n=2), but had no effect with either E/T ratio on colony formation of CD34+ cells derived from normal peripheral blood. Moreover, autologous CLL-1 DashCAR-T cells were successfully prepared from relapsed/refractory AML patients and were demonstrated to mediate specific cytotoxicity to primary AML blasts and LSCs derived from the same patients. Taken together, the CLL-1 DashCAR-T cell candidates have demonstrated excellent anti-AML

potency and efficacy with minimum safety concerns, and warrant to be further developed preclinically for the treatment of relapsed/refractory AML patients.

1299 Use of Highly Enhanced Autologous Natural Killer Cells for Advanced Alzheimer's and Parkinson's Disease

Paul Y. Song[1], Lucia Hui[1], Yoonmi Kang[1], Yongman Kim[2]

[1]NKGen Biotherapeutics, Santa Ana, CA,[2]NKMax, Seoul, Korea, Republic of

Background: Alzheimer's Disease (AD) and Parkinson's Disease (PD) are two very common neurodegenerative diseases with no disease modifying treatments. As more evidence emerges on how misfolded amyloid and alpha-synuclein protein deposits elicit a cascade of autoreactive neuroinflammation and damage, it is clear that removing these proteins by themselves will not fully address the complex process. Natural Killer (NK) cells are an essential part of the innate immune system that have been found to slow progression of amyloid and synuclein protein deposition. NK cells have also been reported to identify and eliminate autoreactive T-cells and damaged neurons via DNAM-1 and NKG2D. But immunosensece has been reported in many patients with neurodegenerative diseases. While NK cells have always been challenging to grow and enhance ex vivo especially when derived from older or heavily pretreated donors, SNK01 is a first-in-kind, autologous non-genetically modified NK cell product with significant increased cytotoxicity and over 90% activating receptor expression that can be consistently produced from any donor. We hypothesize that SNK01 could be consistently produced from any patient with advanced AD or PD, and that it would be safe and potentially beneficial. **Methods:** In preparation for a full Phase I dose escalation study, SNK01 was administered intravenously (IV) to four patients with confirmed advanced AD or PD via compassionate use. **Results:** NK cells were successfully activated and expanded from each patient. Average cytotoxicity was increased over 400% and average activating receptor expression was greater than 90%. There were no adverse events reported in the over 20 total doses given. Each patient had noticeable improvement from their pre-treatment baseline evaluation. **Conclusion:** SNK01 with high cytotoxicity and activating receptor expression can be consistently produced from patients with advanced AD and PD. SNK01 is very safe and may have some clinical activity in AD. This will be expanded into a full Phase I/II trial with a more prolonged dosing schedule.

1300 Engineered Virus-Like Particles Enable High Efficiency of Base Editing in hiPSC-Derived Motor Neurons

Yuan Zhou, Chen Zhang, Haiwen Li, Yuanbojiao Zuo, Renzhi Han

Indiana University School of Medicine, Indianapolis, IN

Base editing shows great promise for the treatment of human diseases. For now, adeno-associated viral (AAV) vectors are the primary delivery vehicles for *in vivo* applications. However, the prolonged expression of base editing agents delivered in AAV may cause accumulations of off-target mutagenesis and increased immunogenicity. A prior study reported that the engineered virus-like particles (eVLPs) could efficiently package and deliver base editor or Cas9 ribonucleoproteins (RNPs) with reduced off-target editing. Here, we used eVLPs to deliver base editors into motor neurons derived from human pluripotent stem cells (hiPSCs) of a spinal muscular atrophy (SMA) patient, who carries homozygous for the deletion of exons 7 and 8 in survival motor neuron 1 (SMN1) gene. The paralogous gene *SMN2* is different from *SMN1* by a silent C-to-T transition in exon 7, resulting in the skipping of exon 7 in most *SMN2* transcripts and production of only low levels of SMN protein. Thus, increasing the exon 7 inclusion in *SMN2* has been pursued as a therapeutic approach for SMA. Our results showed that eVLP-delivered base editor and gRNA induced around 40% T-to-C editing of *SMN2* in motor neurons. The editing increased the expression of full length *SMN2* transcripts. SMN protein was also notably detected in the edited motor neurons. This study highlights the therapeutic potential of eVLP-delivered base editor RNPs for SMA treatment.

1301 Non-Viral Gene Therapy Utilizing Transcutaneous Ultrasound-Mediated Gene Delivery

Barry R. Campbell[1], Surabi Rao[1], Bert Frederich[1], Adel Alonso[1], Brit Ventura[1], David Kim[2], Katie Benthall[2], Brian Christie[2], Julia Poniatowski[2], Ivan Krivega[2], Ken Greenberg[3], Steve Feinstein[3]

[1]Platform Technology, SonoThera, South San Francisco, CA,[2]Gene Therapy, SonoThera, South San Francisco, CA,[3]SonoThera, South San Francisco, CA

Transcutaneous ultrasound-mediated gene delivery (UMGD) is a minimally invasive gene delivery strategy utilizing microbubbles and naked DNA. DNA and microbubbles can be delivered through systemic IV administration and ultrasound used to guide DNA into the cells of the organ of interest. A strong body of literature suggests UMGD as an efficient approach for transgenic DNA delivery into various organs including the liver, kidney, pancreas, and heart. However, the lack of systematic data supporting the efficacy, durability, and safety of ultrasound-mediated gene therapy vector delivery prevents its usage for developing genetic medicines. To confirm the feasibility of using UMGD for efficient transgene delivery in the liver, we developed a reporter transgene expression cassette built in various next-generational non-viral gene therapy vectors. Upon ultrasound-mediated delivery of systemically administrated DNA vectors, strong, durable, and dose-dependent transgene expression was detected in rat and mouse livers. Transgene expression was detected as early as 3 hours post treatment suggesting fast kinetics of DNA delivery to hepatocyte nuclei. Subsequent evaluation of safety endpoints one-day post-treatment showed no elevation of ALT, AST, or IL6 levels in blood, confirming safety of ultrasound-mediated transgene delivery to the liver. This study provides a promising strategy for using minimally invasive ultrasound-mediated transgene delivery of next generation gene therapy vectors for developing genetic medicines.

1302 Automated Monitoring, Analytics, and Machine-Learning for Improved Large-Scale AAV Vector Production

Mark Miller, Brian Williams, Andrey Smelter, Asher Baltzell, Kristin Marks, Jennifer Israel

Kriya Therapeutics, Inc., Research Triangle Park, NC

Manufacturing viral vectors for gene therapy requires large-scale, highly controlled production of recombinant adeno-associated virus (AAV) via expensive and time-consuming processes. Therefore, optimizing these processes to maximize vector quality, minimize expense, and avoid manufacturing failures is critical. We sought to improve the overall yield and purity of AAV manufacturing batches by 1) collecting and analyzing manufacturing equipment data during 50L and 500L AAV manufacturing batches, 2) using these data to benchmark against previous batches, and 3) using these data as inputs to a machine-learning (ML) system that forecasts purified AAV output on a per-batch basis. Throughout upstream and downstream processes, we combined data recorded from in-process instrument readings and assay results, processed these data in automated pipelines, and stored these data in a relational database. We then created online dashboards to communicate manufacturing process trends and in-progress status across the organization. Finally, we identified key predictive features from the batch data as inputs for ML models to forecast ultimate yield and quality for in-progress batches. ML Forecasting models were substantially more accurate than naïve estimates of batch output (i.e. the median output of similar runs) over a sample of 50L and 500L manufacturing batches: these forecasts provide valuable insight into the manufacturing process and are potential inputs for prospectively assessing batch results. Additionally, predictive features identified via automated ML feature selection (e.g. cell viability, metabolite levels) provide candidate targets for subsequent manufacturing process improvements. Overall, this system provides a framework to improve AAV manufacturing output by better understanding the root causes of process variance and prospectively identifying likely manufacturing failures through automated analytics and ML-modeling of the manufacturing process.

1303 Autologous Bone Marrow Aspirate Injection as an Adjunct Biological Treatment in Patients Undergoing Lumbar Microdiscectomy

Ji Tu[1], Pravesh Gadjradj[1], Sertac Kirnaz[1], Alikhan Fidai[2], Branden Mendary[1], Catherine Mykolajtchuk[1], Rachel Yerden[1], Jacob Goldberg[1], Fabian Sommer[1], Lawrence Bonassar[2], Roger Härtl[1]

[1]Department of Neurological Surgery, NewYork-Presbyterian/Weill Cornell Medical Center, New York, NY,[2]Meinig School of Biomedical Engineering, Cornell University, Ithaca, NY

Introduction Lumbar degenerative disc disease (DDD) is a common pathology in the general population that causes severe disability and societal costs. Sciatica caused by lumbar disc herniation is a common consequence of DDD. Though microdiscectomy has positive outcomes for sciatica patients, the degeneration of the discs progresses post-operatively, often resulting in re-herniation of the disc or the worsening of DDD symptoms such as lower back pain. Therefore, alternative treatment options aimed at disc regeneration are warranted. Injection of autologous bone marrow aspirate (BMA) is a potential biological treatment to treat degenerative disc disease, aid in regeneration of the endogenous disc, and alleviate symptoms related to microdiscectomies. However, data on safety of BMA as an intradiscal injection in patients undergoing microdiscectomy are lacking. Therefore, we aimed to assess the safety and feasibility of injecting BMA at the disc site during lumbar discectomy in patients with sciatica. **Methods** A Phase I clinical trial was designed, which included patients with an indication for microdiscectomy due to a single-level, symptomatic, lumbar disc herniation. In this clinical trial, following tubular decompression of the nerve root, processed BMA (harvested from the iliac crest) is injected at the disc site under fluoroscopic guidance. The rest of the surgical procedure is conformed standard practice.Outcome measures include an extensive physical examination, the numeric rating scale (NRS) for leg pain and back pain, and the Oswestry Disability Index (ODI). These data were collected at baseline, 1 day, 3 months, 6 months, and 12 months after surgery. Additionally, MRI-scans were collected at baseline and 3 and 12 months after surgery. Complications were extensively monitored throughout the trial follow-up. This study was approved by the IRB of Weill Cornell Medicine and written informed consent was collected from all patients prior to inclusion. **Results** Thirty-nine patients have been included. At baseline, patients had a mean NRS of 7.5 and 7.0 for leg and back pain, respectively, and an ODI score of 49.3. At 6 months of follow-up, all patient-reported outcome measures showed statistically significant decreases compared to baseline values. Leg pain decreased to 2.0±1.2, back pain to 2.5±1.7 and the ODI to 27.5±11.8. None of the patients experienced (serious) adverse events or complications related to the surgery or BMA-injection. The MRI T2 mapping showed significantly improved for both disc height signal intensity at 12 months follow up. **Conclusion** Based on the data of the included patients, BMA seems to be a safe and feasible potential treatment adjunct to treat lumbar DDD. Further comparative studies are warranted.

1304 A Phenolic-Molecule Mediated Co-Delivery System for Multiple AAV Vectors

Zheng Rong Lau[1], Miri Kim[2], Il-Sun Kim[2], Yu Ri Nam[3], Sung Jin Lee[4], Ginah Han[1], Haeshin Lee[3], Jeong Eun Shin[2], Jae-Hyung Jang[1,4]

[1]Department of Chemical and Biomolecular Engineering, Yonsei University, Seoul, Korea, Republic of,[2]Yonsei Biomedical Research Institute, Yonsei University College of Medicine, Seoul, Korea, Republic of,[3]Department of Chemistry, Korea Advanced Institute of Science and Technology (KAIST), Daejeon, Korea, Republic of,[4]GluGene Therapeutics Inc., Seoul, Korea, Republic of

Introduction Biomedical techniques often require simultaneous delivery of multiple adeno-associated viral (AAV) vectors, especially in CRISPR gene editing and direct reprogramming. However, sample dilution during delivery can hinder the efficacy of delivering all vectors into each target cell, therefore requiring a novel delivery system for robust co-delivery of multiple AAV vectors. **Methods** Biomimetic phenolic molecules have a strong affinity for peptides and biomolecules. Previous research indicated that polyphenolic molecule-treated AAV vectors improved heart transduction *in vivo*. Our hypothesis is that the peptide affinity of phenolic molecules could enhance co-delivery of multiple AAV vectors. To test this hypothesis, we conducted *in vitro*

and *in vivo* experiments and analyzed the co-expression of delivered genes. We also generated a hypoxic ischemic encephalopathy (HIE) mouse model and co-delivered multiple factors to directly reprogram reactive astrocytes into functional neurons, evaluating the recovery of sensory and motor functions. **Results** Our *in vitro* experiments revealed improved co-transduction efficiency of multiple AAV vectors with phenolic molecule treatment, despite localized cell administration. *In vivo* delivery to HI-injured mouse brains showed increased gene expression in reactive astrocytes, as demonstrated by dual staining of GFP and astrocyte markers. The proportion of cells co-transduced with GFP and E2crimson was also higher when treated with phenolic molecules. Lastly, the recovery of sensory and motor functions in mouse models with HI injury through the *in vivo* direct reprogramming of reactive astrocytes into functional neurons will be discussed further. **Conclusion** This study is the first to show improved co-transduction of multiple AAV vectors with phenolic molecules. Future research will focus on optimizing the formulation and exploring its use in CRISPR gene editing and co-expression of intein-split peptides. Overall, the ability to effectively co-transduce multiple vectors has the potential to enhance the therapeutic outcomes of both biomedical and genetic techniques.

1305 IL-2 Preferentially Expands a Less Functional, CD27-Negative CAR T Cell Subset and Compromises Antitumor Potency

Dongrui Wang[1], Xinghua Liang[1], Darya Alizadeh[2], Renate Starr[2], Alfonso Brito[2], Brenda Aguilar[2], Lu Xiao[3], Yongxian Hu[1], Behnam Badie[2], He Huang[1], Stephen J. Forman[2], Christine E. Brown[2]

[1]The First Affiliated Hospital of Zhejiang University School of Medicine, Hangzhou, China,[2]City of Hope National Medical Center, Duarte, CA,[3]Canyon Vista Medical Center, Midwestern University Consortium, Sierra Vista, AZ

Chimeric antigen receptor (CAR) T cell therapy has been a promising approach to treat some hematological malignancies, but treatment failure and disease relapse are frequently observed across different clinical studies. The characteristics and fitness of CAR T cell products, especially the memory-like phenotypes, have been shown to closely correlate with therapeutic outcomes. *Ex vivo* expansion, usually supplemented with interleukin (IL)-2, is necessary for generating clinical-grade CAR T cell products, but extended expansion can also result in the loss of memory-associated signatures and a compromised effector potency. The cellular dynamics of CAR T cells during *ex vivo* expansion and its impact on antitumor function, however, remain poorly understood. Here we revealed that the expression of CD27, a memory-associated costimulatory molecule, gradually decreased during IL-2-mediated CAR T cell expansion. On the other hand, a differentiated, effector-like CAR T cell subset characterized by the lack of CD27 expression (CD27-), was particularly responsive to IL-2-driven expansion, which became dominant and occupied more than 90% of total CAR T cells after extended culture. This CAR T cell subset was also featured by the exclusive expression of T cell activation markers including CD25 (IL-2 receptor), and the superior responsiveness to IL-2 as demonstrated by a >10 fold proliferative advantage over CD27-expressing (CD27+) CAR T cells. Despite their expansion potency with IL-2, the CD27- CAR T cells were less functional compared to CD27+ cells, especially against large xenograft tumors as well as tumor cells with low antigen expression. The induction of CD27 costimulatory signal requires the interaction between CD27 and its ligand CD70; consistently, the cytotoxicity of CD27+ CAR T cells against CD70-expressing tumor cells was diminished with CD70-blocking antibodies. Meanwhile, CAR-driven tonic signaling and the subsequent acquisition of early-exhaustion signatures, mainly occurred in the CD27- subset. Further, we analyzed 58 CAR T cell products expanded in IL-2, and revealed that CD27 expression was correlated with effector function against recursive tumor cell challenge. The outgrowth of CD27- CAR T cells was suppressed using IL-15-mediated expansion, generating memory-like CAR T cell products and enhanced antitumor efficacy. These results provided the cellular mechanism of IL-2-driven differentiation when expanding therapeutic T cells, revealing the critical need to refine manufacturing procedures and preserve CD27-expressing CAR T cells. This work also suggested the potential of CD27 as a biomarker for the functional quality of CAR T cell products.

1306 LNP-AAV Hybrid Delivery of a DNA Gene Writer System Corrects Severe Ornithine Transcarbamylase Deficiency in Neonatal Mice and Improves AAV Potency in Adult Mouse and NHP Livers

Philip Zakas[1], Sharon C. Cunningham[2], Ann Doherty[1], Stephanie Yu[1], Bef Mekonnen[1], Raed Ibraheim[1], Brendan Lang[1], Elizabeth English[1], John Solitro[1], Mayuri Singh[1], Eva B. van Dijk[2], Gang Sun[1], Miles Duncan[1], Matthew Benczkowski[1], Robert C. Altshuler[1], Malvenderjit Jagjit Singh[1], Emily Kibbler[1], Gulen Tonga[1], Jane Wang[1], Guangde Li[1], Jeff An[1], James B. Rottman[1], Yanfang Fu[1], Robert J. Citorik[1], Jacob R. Rubens[1], Cecilia Cotta-Ramusino[1], William Querbes[1], Ian E. Alexander[2,3], William E. Salomon[1]

[1]Tessera Therapeutics, Somerville, MA,[2]Gene Therapy Research Unit, CMRI, Westmead, Australia,[3]Discipline of Child and Adolescent Health, Sydney Medical School, The University of Sydney, Westmead, Australia

The use of adeno-associated virus (AAV) for gene transfer and the treatment of genetic diseases has tremendous promise but continues to face challenges in clinical translation such as dose-limiting toxicity and dilution and/or loss mediated by target cell division. One approach to overcome these challenges is to apply methodologies that integrate genes into the genome using integrating viral vectors or by utilizing nuclease-mediated gene transfer. These approaches offer some improvement over AAV's episomal expression in durability of effect but still have undesirable safety risks and/or limited efficiency. To address some of the limitations of previous genetic therapies, we utilize Gene Writer systems - an engineered mobile genetic element - along with its cognate nucleic acid template that is used for integration into the genome. Here, we describe a DNA Gene Writing system that co-delivers the *Sleeping Beauty* (SB) transposable element mRNA via a lipid nanoparticle (LNP) along with an AAV encoding a template for correction of ornithine transcarbamylase deficiency (OTCD) in the *spf^{ash}* neonatal mouse model. The transient mRNA expression of the SB transposable element combined with AAV delivery of the human OTC gene DNA Writer template mediated genomic integration and

led to sustained phenotypic correction of urinary orotic acid levels over 10 weeks. When neonatal mice were treated with the AAV delivered DNA Gene Writer template alone or with an AAV construct designed to express hOTC episomally, the level of hOTC expression when mice reached early adulthood was sub-optimal which resulted in orotic acid levels comparable to untreated mice. Only animals that received the complete DNA Gene Writer system survived after residual murine OTC activity was significantly reduced by silenced expression with an shRNA. Furthermore, application of the LNP-AAV hybrid delivery of the SB DNA Writer system to adult mice or NHPs allows for significant improvement of AAV mediated gene transfer. In adult mice, we demonstrate a nearly 40-fold increase in reporter production delivered with our Gene Writer system compared to an equivalent dose of AAV alone - an effect that cannot be attributed to cell division loss in an adult mouse. In NHP we demonstrate, through use of the non-immunogenic secreted reporter rhesus chorionic gonadotropin β-subunit (rhCG), that the DNA Writer driven stable integration shows 10-fold increased serum concentrations after 13 weeks and did so with enhanced potency, requiring a 5-fold lower AAV dose. Utilization of the SB DNA Gene Writer system could enable dosing at a lower and safer level of AAV as compared to higher levels required for traditional AAV episomal driven expression. Although the current SB DNA Gene Writer system is not site-specific, it is specific in the DNA sequence that is integrated as opposed to random AAV genome integration. These findings of stable and potent delivery of genes mediated by a DNA Gene Writer system exemplify the transformative potential of Gene Writing *in vivo* to treat devastating genetic diseases.

1307 Delivery of PMP22-Targeting shRNA by ARMMs as a Disease-Modifying Therapeutic Approach for Charcot Marie Tooth 1A

Nedyalka Valkov, Shu-Lin Liu, Chris Chatzinakos, Bhavesh Gurwani, Qiyu Wang, Lucy Sun, Kristin Luther, Adam Francoeur, Leah Gens, Alysia Bryant, Joseph F. Nabhan

Vesigen Therapeutics, Cambridge, MA

Charcot Marie Tooth type 1A (CMT1A) is a genetic disease caused by duplication of the Peripheral Myelin Protein 22 (PMP22) gene. It is considered the most common inherited demyelinating peripheral neuropathy. Overproduction of the PMP22 protein in Schwann cells leads to myelin loss, axonal damage, and muscle atrophy. Reducing PMP22 expression to non-carrier levels is likely to alter the course of disease. However, to date, there are no disease-modifying therapies for patients due to the absence of an appropriate vehicle that safely deliver molecules, such as short hairpin RNA (shRNA), to suppress PMP22 expression levels in the disease-affected Schwann cells. We engineered ARMMs (ARRDC1 mediated microvesicles), a distinct class of human extracellular vesicles, to actively load short hairpin RNA (shRNA) using ARRDC1 fused to an RNA-binding domain as an active recruitment handle. In non-human primate (NHP) biodistribution studies, we identified Schwann cells as a specific target cell type transfected by ARMMs after intrathecal administration. Using an *in silico* screening approach we prioritized human and NHP PMP22 targeting shRNA sequences, that 1) may yield optimal shRNA knockdown; 2) have limited potential off-target activity; and 3) can target both NHP and human PMP22 transcripts. shRNA candidates loaded into ARMMs were shown to yield functional delivery as evidenced by target engagement in human primary Schwann cells. PMP22 targeting shRNA delivered via ARMMs downregulated PMP22 mRNA in a dose-dependent manner and reduced PMP22 protein levels in Schwann cells. Our data provide evidence for the therapeutic potential of ARMMs loaded with PMP22 shRNA as a disease-modifying strategy for CMT1A.

1308 Synthetic DNA Templates Accelerate Development of mRNA Based Therapeutics and Vaccines

Amy Walker, Ángel Picher, Heikki Lanckriet

4BaseBio, Cambridge, United Kingdom

The manufacture of high-quality, GMP grade DNA is a major bottleneck in the production of mRNA for use in gene therapy and vaccines. 4basebio has developed a proprietary, scalable synthesis process for the production of linear DNA constructs via our Trueprime™ amplification technology. The opDNA™ produced is devoid of any bacterial backbone and the manufacturing process circumvents cumbersome fermentation processes required for plasmid DNA. The process is size and sequence independent, enabling the incorporation of polyA tails >120 bp, and allows for large scale production of linear DNA with high yield and purity in less than a week. Unlike plasmid DNA, 4basebio DNA eliminates contamination from endotoxins or host proteins, and excludes bacterial sequences such as antibiotic resistance genes. Critically, opDNA ™ does not need to be linearised prior to use in an IVT reaction, removing an enzymatic step from mRNA bioprocessing workflows. Here, we compared the synthesis of *in vitro* transcribed (IVT) mRNA using opDNA™ versus linearised plasmid DNA, and achieved significantly higher mRNA yields irrespective of construct size, ranging from 1.8kb reporter genes to 9.5kb samRNA constructs. Proinflammatory cytokine/chemokine levels in primary human PBMCs were comparable to mRNA produced from linearised plasmid, as was 3‘ heterogeneity of the transcripts and levels of dsRNA impurities. 4basebio's targeted, non-viral delivery platform, Hermes™, allows targeting towards specific cells or tissues of interest, and is suitable for a range of nucleic acid and biological payloads. Using Hermes™ nanoparticles, mRNA reporter constructs were encapsulated and transfected in a range of cells models (HEK293, C2C12, primary human chondrocytes and primary human hepatocytes, PBMCs), and transgene expression was equivalent to mRNA produced from linearised plasmid. Comparable expression was also achieved in mouse models via I.M and I.V routes of administration. We have demonstrated that opDNA™ templates can be used for the production of IVT mRNA. Moreover, the technology could overcome the difficulties associated with complex polyA tails for mRNA constructs, which are inherently difficult to synthesise via bacterial propagation systems. The combination of 4bb mRNA and Hermes™ non-viral delivery platform can greatly accelerate the therapeutic development of gene therapy and vaccine programmes.

1309 Generation of HLA-A2-Specific CAR Engineered CD8 Tregs with Robust *In Vitro* and *In Vivo* Suppressive Activity

Subhash Kumar Tripathi[1], Noelle P. Dahl[1], Peter J. Cook[1], Yuchi Honaker[1], Martina Hunt[1], David J. Rawlings[1,2]

[1]Center for Immunity and Immunotherapies, Seattle Children's Research Institute, Seattle, WA,[2]Departments of Pediatrics and Immunology, University of Washington, Seattle, WA

Regulatory T cells (Treg) are key players in peripheral immune tolerance and homeostasis. Thymic derived, endogenous CD4 and CD8 tTreg exhibit regulatory activity across a wide range of animal models and human diseases, including autoimmune disorders, solid organ transplantation and graft vs. host disease (GvHD). Adoptive transfer of gene edited, engineered Treg (EngTreg) has emerged as promising therapeutic approach to induce immune tolerance. We previously described use of homology-directed-repair (HDR)-based gene editing to introduce a ubiquitous promoter into the *FOXP3* locus to generate CD4+ EngTreg with high level FOXP3 expression and stable Treg phenotype and function. In comparison to polyclonal Treg, antigen-specific Treg are vastly more efficient in suppressing autoimmune responses and preventing disease in vivo. As an approach to achieve antigen specificity in organ transplant or GvHD, several groups have introduced chimeric antigen receptors (CARs) derived from anti-HLA-A*02 specific mAbs (A2-CAR) into human tTreg. Compared to polyclonal tTreg, A2-CAR tTreg exhibited more potent suppression of immune responses induced by HLA-A*02 mismatched Teff. In the current study, we expand upon these previous efforts, by utilizing HDR-gene editing and LV delivery to generate either CD4 or CD8 A2-CAR EngTreg. Notably, as part of the HDR editing cassette, we introduced FRB-IL2RB and FKBP-IL2RG fusion proteins (referred to hereafter as chemically inducible signaling complex or CISC), to mediate IL2 like signaling in the presence of a chemical dimerizer, e.g., rapamycin or rapalog. Using this approach, CD4 and CD8 CISC A2-CAR EngTreg were generated and enriched to high purity using rapamycin. Cell products exhibited stable A2-CAR and FOXP3 expression, expression of key Treg markers, and minimal proinflammatory cytokine production but robust TGF-β expression upon stimulation. Like their CD4 counterpart, CD8 A2-CAR EngTreg were able to suppress effector T cell proliferation. Next, we tested whether CD4 or CD8 A2-CAR EngTreg could suppress effector T cells in an allogeneic GvHD NSG model. Our data show that both CD4 and CD8 A2-CAR EngTreg exhibit robust suppressive capabilities against HLA-mismatched allogeneic effector T cells in NSG recipient mice. To compare the effective dose of CD8 vs. CD4 A2-CAR EngTreg, we performed a dose response study that revealed marked efficacy of CD8 A2CAR EngTreg in the allo-GvHD NSG model. Together, our results demonstrate the relevance of the CAR engineering and T cell editing approach to develop antigen-specific CAR/CISC expressing CD8+ EngTreg with potential for clinical application in transplantation, and potentially in other diseases.

1310 A Novel Rat Model for Type A Cystinuria Replicates Pathobiological Features Observed in Patients

Florin Craciun[1], Nicholas Ngai[1], Mandy Smith[1], Matthew Deriso[2], Xiaoyou Ying[2], Mostafa Kabiri[3], Lilu Guo[4], Christian Mueller[1], Herve Husson[1]

[1]GMU, Sanofi, Waltham, MA,[2]TIMS, Sanofi, Cambridge, MA,[3]TIMS, Sanofi, Frankfurt, Germany,[4]PMCB, Sanofi, Cambridge, MA

Cystinuria (CYS) is the most common rare kidney stone disease, affecting ~14 in 100,000 individuals globally. It is caused by mutations in either SLC3A1 gene encoding for rBAT (type A cystinuria) or SLC7A9 gene encoding for b0,+AT (type B cystinuria) subunits of a neutral and basic amino acid transporter of Cystine, Ornithine, Lysine and Arginine (COLA) expressed in the kidney proximal tubular epithelial cells and in the intestine. If all COLA have been shown to be increased in urine, only increased cystine levels lead to precipitation of crystals and continuous formation of stones in the urinary tract. The current standards of care aim to prevent calculi formation aim at reducing the concentration of cystine (ie diet), increase its solubility (ie D-penicillamine and mercaptopropionylglycine), or to dissolve stones that have formed over time by lithotripsy (ie ultrasound). However, they have limited efficacy and cause adverse events leading to poor drug compliance and stone recurrence which may lead to kidney damage and even kidney failure in some cases. Patients require repeated ureteroscopy interventions to remove larger stones if they are not eliminated naturally. We engineered a new CYS rat model by deleting exons 1 and 2 of the Slc3a1 gene. This deletion caused complete loss of Slc3a1 mRNA and protein expression in kidney proximal tubules of rats that are homozygote for the KO allele (HOM), with normal expression maintained in heterozygotes (HET). SLC7A9 protein expression was also altered in HOM, with an intracellular localization detected in the proximal tubule compared to apical plasma membrane location in wild-type (WT) and HET. The lack of transporter resulted in a specific increase in urinary COLA in HOM animals. Cystine concentrations were above the solubility level for all HOM rats at 8 weeks of age, the earliest time measured. All KO rats had numerous pathognomonic hexagonal crystals in urine. Bladder stones were detected by μCT scan as early as 9 weeks of age in some of the animals. By contrast, all HET animals had normal urinary COLA levels. Overall, this novel rat model of CYS recapitulates the pathobiological features of the disease observed in humans. We plan to use the CYS rat for pharmacological testing of novel therapeutic interventions for this debilitating disease with high unmet medical need.

1311 Weak Promoter and High Vector Dose to Restore Retinal Function in FAM161A Deficient Ciliopathy (RP28)

Yvan Arsenijevic[1], Younes El Fersioui[1], Ning Chang[1], Carlo Rivolta[2], Eyal Banin[3], Dror Sharon[3], Corinne Kostic[4]

[1]University of Lausanne, Hôpital Ophtalmique Jules-Gonin, Lausanne, Switzerland,[2]Institute of Molecular and Clinical Ophthalmology Base, Basel, Switzerland,[3]Hadassah-Hebrew University Medical Center, Jerusalem, Israel,[4]Jules Gonin Eye Hospital, Lausanne, Switzerland

FAM161A encodes for a protein expressed in the photoreceptor connecting cilium (CC). Biallelic loss of function mutations in this gene cause autosomal recessive retinitis pigmentosa-28 (RP28). No treatment exists to cure or slow down disease progression. We developed a gene augmentation approach to restore retinal function and slowdown retinal degeneration. The human *FAM161A* gene produces two major isoforms (Long, L; Short, S) in the retina. We first tested in PN15 *Fam161a* knockout mice AAV2/8 vectors (10^{10} genome copies, GC/uL) coding for IRBP-GRK1-L or -S, or in combination. Single vectors did not improve retinal function, but partially protected the retina. At 3 month post-injection (mpi) of vector combination (L+S), FAM161A was expressed in the CC but also extended to the photoreceptor cell body and behind. ONL was thicker in treated eyes compared to control eyes by around 200%, but retinal function (in scotopic condition) only transiently and modestly improved at 2 mpi (P=0.0055), being similar to control eyes at 3 mpi (n=18 for each group). A lower vector dose (10^{9} GC/uL) did not ameliorate the treatment effect. We thus investigated whether a fine regulation of the protein expression is necessary to recover retinal function and tested with the AAV2/8 vector the endogenous core *FAM161A* promoter with the Crx-binding-region-1 (CBR1) or CBR2. At PN14, the subretinal injections of the CBR2-core-S *hFAM161A* vector (10^{10} GC/uL) provoked a robust gene expression in the CC and ONL at 1 mpi (n=9), while CBR1-core-S (n=6) vector induced a faint expression, only in the CC. A higher injection dose of CBR1-S or L vectors (10^{11} GC/uL) increased the number of FAM161A-positive CCs only, but did not improve retinal activity (n=5 and 7 respectively). However, co-injection of CBR1-core L and S vectors ($0.5x10^{11}$ GC/uL each) induced both homogenous retina labelling in the CC only and functional improvement 3 mpi (n=4, P=0.0004). Retinal integrity was also best improved by administering combinations of vectors. The ONL thickness was similar to WT retina where FAM161A-positive CC density was the highest. We thus propose to use the weak *FAM161A*-core promoter with *CBR1* and high vector doses to treat RP28 with the two isoforms of the FAM161A gene.

1312 Gene Therapy Candidate for Metachromatic Leukodystrophy (MLD): Optimization of HMI-204 Development Candidate

Jacinthe Gingras[1], Thia St Martin[1], Katherine Gall[1], Andrew Pla[2], Jason Lotterhand[1], Israel J. Rivas[1], Nancy Avila[1], Jenn Newman[1], Teresa Wright[3], Omar Francone[1], Albert Seymour[3]

[1]Homology Medicines, Inc., Bedford, MA,[2]Prevail Therapeutics, New York, NY,[3]Homology Medicines, Bedford, MA

Metachromatic leukodystrophy (MLD) is an inherited autosomal recessive lysosomal storage disorder (LSD) with a great unmet medical need. This fatal neurodegenerative LSD occurs in three forms: late infantile (prevalence of 1 in 40,000), juvenile, and adult. The first two forms represent the majority of the MLD patients where mortality at 5 years is estimated at 75% and 30%, respectively. MLD is most commonly caused by mutations in the *ARSA* gene and patients suffering from the disease are deficient in arylsulfatase-A (ARSA) enzyme activity. The disease is characterized by accumulation of sulfatides to supraphysiological toxic levels in the peripheral organs and nervous system. In the brain, excess sulfatides lead to the destruction of myelin, a key protective sheath that forms a layer around the nerve fibers that enhances propagation of action potentials. Herein, we report the outcome of the optimization and nomination of a development candidate, HMI-204, for the treatment of MLD. The optimization addressed both biology and manufacturability. The goal was to maintain an intravenous (I.V.) delivery route for HMI-204 to target this disease systemically, while also providing the expression of high levels of ARSA activity in the brain of *Arsa* knockout (KO) mice, predicted to lead to direct motor deficit improvements as demonstrated with the previous lead construct. The team also sought to lower, but not eliminate, ARSA expression in the heart tissue. Following a single I.V. dose of HMI-204, anti-ARSA expression patterns in the brain of adult *Arsa* KO mice remained nearly identical to that of anti-murine Arsa distribution in wild type age-matched littermates, confirming successful crossing of the blood-brain barrier (BBB). A dose-response in ARSA brain activity was achieved in adult and neonate *Arsa* KO mice, reaching normal human levels of expression as measured in normal post-mortem human brain tissue samples. This range covered the expression levels predicted to lead to motor deficit prevention in the MLD mouse model (50-100% of normal human levels) across multiple doses. In the heart of adult *Arsa* KO mice, the biodistribution of anti-ARSA was significantly reduced, while that in the liver remained similar, when compared to the previous lead construct. In neonatal mice, a dose-response in ARSA activity was achieved in heart and liver tissues, as well as in serum, leading to a durable systemic expression for the entire study duration (12 weeks). Lastly, the manufacturing productivity profile of HMI-204 (vg/L) was substantially improved as compared to the previous lead construct. In summary, a single I.V. dose of HMI-204 achieved a broad and sustained systemic biodistribution, including the central nervous system, while lowering expression in heart tissues. Levels of ARSA activity detected in each organ tested reached normal human levels for the corresponding organ, at one or multiple doses. Lastly, the optimization improved both the biological

and manufacturability profile of HMI-204 and these preclinical data continue to support the potential of HMI-204 as an effective gene therapy for the treatment of MLD.

1313 CRISPR-Cas9 *RAG2* Correction via Coding Sequence Replacement to Preserve Endogenous Gene Regulation and Locus Structure

Ayal Hendel[1], Daniel Allen[1], Orli Knop[1], Bryan Itkowitz[1], Ortal Ortal Iancu[1], Katia Beider[2], Yu Nee Lee[3], Arnon Nagler[2], Raz Somech[3]

[1]The Mina and Everard Goodman Faculty of Life Sciences, Bar Ilan, Ramat Gan, Israel,[2]The Division of Hematology and Bone Marrow Transplantation, Sheba Medical Center, Ramat Gan, Israel,[3]Pediatric Department A and the Immunology Service, Sheba Medical Center, Ramat Gan, Israel

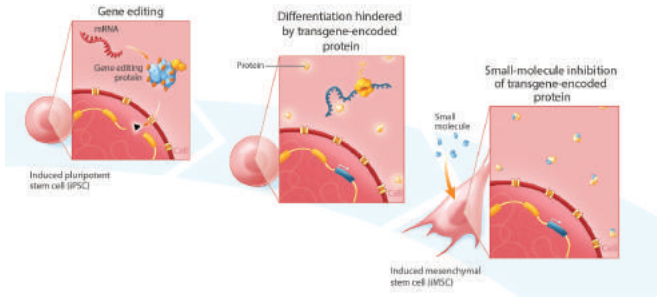
RAG2-SCID is a primary immunodeficiency caused by mutations in *Recombination-activating gene 2 (RAG2)* which is intimately involved in the process of lymphocyte maturation and function. *Ex-vivo* gene editing of a patient's own hematopoietic stem and progenitor cells (HSPCs) using a combination of CRISPR-Cas9 and rAAV6 vectors could provide a therapeutic alternative to the only current treatment for *RAG2*-SCID, allogeneic hematopoietic stem cell transplantation (HSCT). To do so, we established the most conducive transgene design for efficient homology directed repair (HDR) at the *RAG2* genomic locus while maintaining endogenous regulatory and spatiotemporal elements. As a proof-of-concept single-allelic gene correction, we established a *knock-in/knock-out (KI-KO)* strategy in healthy donor (HD)-derived $CD34^+$ HSPCs via multiplexed HDR. *KI* of our *RAG2* correction donors that replaced the entire endogenous *RAG2* coding sequence (CDS) to preserve endogenous gene regulation and locus architecture led to successful development from $CD34^+$ HSPCs into $CD3^+TCR\alpha\beta^+$ and $CD3^+TCR\gamma\delta^+$ T cells and promoted the development of highly diverse TRB and TRG repertoires in an *in-vitro* T-cell differentiation (IVTD) platform. We present a method to correct the *RAG2* gene while maintaining *RAG2* expression regulation and locus structure and a workflow to determine the optimal configuration for CRISPR-Cas9/rAAV6 correction of genes with strict spatiotemporal gene regulation.

1314 Directed Differentiation of Gene Edited iPSCs by Small-Molecule Inhibition of a Transgene-Encoded Protein

Raven Dance Klee[1], Taeyun Kim[2], Kyle M. Garland[1], Christopher B. Rohde[2], Matthew Angel[1,2]

[1]Eterna Therapeutics, Inc., Cambridge, MA,[2]Factor Bioscience, Inc., Cambridge, MA

Indoleamine 2,3-dioxygenase 1 (IDO1) is an inducible, heme-containing enzyme that is critically involved in tryptophan catabolism and known to be a prominent immune regulator. Cell therapies with increased IDO1 expression are of high interest for a variety of indications, including autoimmune disorders, inflammatory diseases, transplant recovery, and wound healing. In particular, iPSC-derived mesenchymal stem cells (iMSCs) engineered to overexpress IDO1 may be ideal for suppressing dysregulated immune cells while simultaneously promoting expansion of regulatory T lymphocytes and the M1 (pro-inflammatory) to M2 (anti-inflammatory) polarization of macrophages. Here, we report the development of an iMSC cell line containing an IDO1 transgene under the control of a JeT promoter that was inserted into the AAVS1 safe-harbor locus in mRNA-reprogrammed iPSCs. A clonal population of edited cells (*i.e.* IDO1-iPSCs) was isolated using single-cell sorting. Bi-allelic insertion of the IDO1 transgene was confirmed by amplicon sequencing. The IDO1-iPSCs were then differentiated to IDO1-iMSCs. During differentiation, we found that the IDO1-iPSCs showed an unexpected, cuboidal morphology and noticeably decreased proliferation rates relative to control iPSCs, possibly indicating that IDO1 was interfering with the differentiation process. Two small-molecule IDO1 inhibitors, Epacadostat, which binds to holo (heme-bound) IDO1 and inhibits the enzymatic function of the protein and IDO1-IN-5, which binds to apo (heme-dissociated) IDO1 and inhibits IDO1-dependent cell signaling, were added to the culture for the final five days of differentiation. The addition of both IDO1 inhibitors (each at a 10μM concentration) increased the proliferation of the partly differentiated IDO1-iPSCs (6 h reduction in doubling time) with a population doubling time approaching that of control iMSCs (29 h vs. 27 h). While both inhibitors could enhance proliferation independently, Epacadostat alone had a larger effect on population doubling time than the IDO1-IN-5 alone (6 h vs. 2 h reduction in doubling time), suggesting that the anti-inflammatory enzymatic function of IDO1 may be most responsible for decreased proliferation during differentiation of IDO1-iPSCs. Notably, we also found that when administering both IDO1 inhibitors to non-engineered control iMSCs, the population doubling time increased relative to untreated test cultures (34 h versus 27 h), suggesting a possible minimum IDO1 protein level required for optimal iMSC culture. These results suggest that small-molecule inhibition of transgene-encoded proteins may form a key element of directed differentiation process development for knock-in iPS cell lines, and may be useful for the scale-up manufacturing of IDO1-iMSCs in particular.



1315 PKC Agonists as Small Molecule Inducing Agents for Enhancing Lentiviral Vector Production

Charles Moore-Kelly, Thomas M. Evans, Jordan Wright, Dan C. Farley, Ian T. Matthews, David Pulido-Gomez, Olotu Ogonah, Kyri Mitrophanous, Nicholas Clarkson, Rui André Raposo

Oxford Biomedica, Oxford, United Kingdom

Achieving high upstream lentivector (LV) titres is fundamental to the development and manufacture of a commercially viable gene therapy

product. However, product titres can vary considerably with different therapeutic transgene sequences despite being produced in the same mammalian cell system, so implementing new technologies that are able to recover low titres or improve high titres further can be invaluable. Induction is a key stage of the upstream LV production process that typically involves increasing the expression of LV genes in production cells with the histone deacetylase inhibitor, sodium butyrate. A series of recent screening experiments revealed to us that titres of LV products can be further increased by using an additional class of molecules known as PKC agonists alongside the induction step. Here, we describe how, through optimisation of dosing concentration and timing, LV titres can be enhanced 2- to 9-fold with the non-tumour promoting PKC agonists prostratin and ingenol 3-angelate in a product-specific manner. Importantly, LV produced using PKC agonists have comparable or superior particle-to-infectivity ratios, and residual PKC agonists are removed from the vector product following downstream processing. Furthermore, we demonstrate that PKC agonists act synergistically with an in-house technology based on LV RNA-targeted U1 snRNA to achieve log-fold-increases in titre without detriment to product quality attributes. Having established the benefits of introducing PKC agonists to our platform process and in our packaging/producer cell lines, we provide insight into the mechanisms by which these agonists are acting on production cells and now intend to transfer this technology to GMP manufacturing for commercial products.

1316 Translating Preclinical Efforts into Clinical Gene Therapy Trials: A Systematic Literature Review in the Leukodystrophies

Jasna Metovic, Yi Gong, Amanda Nagy, Florian Eichler

Department of Neurology, Massachusetts General Hospital, Harvard Medical School, Boston, MA

Background: Leukodystrophies are progressive single gene disorders affecting the white matter of the brain. Several gene therapy trials are emerging to address the unmet need in this patient population. Yet many preclinical efforts stall and do not progress to trials in humans. **Methods:** We performed a comprehensive literature review using the PubMed online electronic database regarding the application of gene-based therapies in leukodystrophies and compared these results to trial listings in www.clinicaltrials.gov, through January 2023. The search was performed using the following keywords: "name of the disease" AND gene therapy. We noted which indications and approaches had received approval by EMA or FDA. Where available, delivery route, targeting cell type, and side effects of treatments were documented. **Results:** Among the approximately 30 disorders characterized as classic leukodystrophies (Vanderver et al, 2015), only 5 have progressed to clinical trials in the field of gene or cell therapy, namely, metachromatic leukodystrophy, X-linked adrenoleukodystrophy, globoid cell leukodystrophy, Canavan disease and Alexander disease. Preclinical studies focusing on varied treatment approaches have been published in another 9 well-characterized disorders, that had not entered human trials yet. While multiple therapeutic approaches have been studied in leukodystrophies including *in vivo* (e.g., adeno-associated virus), *ex vivo* (e.g., lentiviral), and antisense oligonucleotides, only *ex vivo* lentiviral gene therapy for X-linked adrenoleukodystrophy has thus far received EMA or FDA approval. Several challenges emerged in both preclinical and clinical studies: chemical design, proper cell targeting and successful intracellular delivery, intervention window, immunogenicity of the viral vector and associated transgene leading to safety concerns. **Conclusions:** Even in preclinical studies of gene and cell therapy a careful alignment of biological characteristics and target cells specific to each leukodystrophy and trial design recognizing mechanisms relevant to the intervention window is essential. Standardizing monitoring procedures and management of immune responses will need to be addressed before these types of therapies become a widely accepted treatment in the leukodystrophies.

1317 A Robust AAV Production Platform with a Novel 293 Cell Line

Huimin Kong, Huilan Zhang, Peng Zhang, Yanqun Shu, Jay Hou

Skyline Therapeutics, Cambridge, MA

In the past decade, recombinant Adeno-Associated virus (rAAV)-based gene therapies have attracted increasing interest for the treatment of monogenic disorders. Complexity and cost of large-scale rAAV production are still serious obstacles for the development and commercialization of AAV gene therapy products. Several platforms are commonly used to produce rAAV, such as transient triple plasmid transfection of HEK293 cells, recombinant herpes simplex virus (rHSV) infection of HEK293 (or BHK-21) cells, recombinant baculovirus infection of *Spodoptera frugiperda 9* (Sf9) cells, and stable rAAV producer cell lines. Currently, triple transfection of HEK293 cells is the most popular platform due to its simplicity, flexibility and potential for facilitating the vector development from research to clinic trials. To increase the production efficiency and yield, we had spent effort on selection of single cell clones that produced rAVV with high yield. Out of 234 clones, a HEK293 clone, 8F8-4G1, was identified, which produced 3-7 fold more viral vectors compared to parental cell line. The cells were cultured in serum-free medium and grown in suspension, therefore the culture volume could be readily scaled up. In addition, the cell line is stable and can be cultured for multiple passages with high density. After further optimization, with this rAAV production platform, same quantity of the vector was produced using 3-7 fold less culture volume than its parental cell line for large-scale production, resulting consequently in 3-7 fold reduction in the cost. The establishment of the platform with this novel cell line will greatly accelerate the vector research and discovery, and facilitate the cost control in CMC manufacture.

1318 Development and Optimization of Novel Super piggyBac®-Based Hybrid Gene Therapy Approach

Bernard Kok, Kevin Johnson, Peter Griffin, Fernando Lopez, Mu Li, David Ebeid, Nairika Meshgin, Ryan Loveless, Johannes Schwerk, Khal Hajj, Michael Bennett, Pavan Battiprolu, Brent Warner, Blair Madison, Joshua Rychak

Poseida Therapeutics, San Diego, CA

Conventional adeno-associated virus (AAV) therapies have provided an avenue to treat a broad range of diseases. Despite their advantages, AAVs exhibit limited durability when applied early in life. Transgenes
